## Abstract

Advanced functionalized nanomaterials are indispensable for the efficient production of solar fuels via the reduction of CO<sub>2</sub> under solar light. This approach simultaneously addresses two major issues: (a) global warming due to anthropogenic CO<sub>2</sub> production and (b) the ongoing energy crisis. Owing to their high catalytic activity and visible-light absorption, MoS2 has recently emerged as a suitable candidate for the photocatalytic production of solar fuels from water splitting and CO<sub>2</sub> reduction. However, it currently shows poor conversion efficiency because of low adsorption of reactant gases, fast radiative recombination, and low chemical stability; these factors limit their practical applicability. In this CO<sub>2</sub> photoreduction and H<sub>2</sub> production were enhanced by integrating photoabsorber MoS<sub>2</sub> and N-containing conducting polymer polypyrrole (PPy) on reduced graphene oxide (rGO). rGO-MoS<sub>2</sub>/PPy nanocomposites with various amounts of PPy were fabricated and morphologically, structurally, and optically characterized using several techniques. The optimal rGO-MoS<sub>2</sub>/PPy nanocomposite was found to exhibit a remarkable production of CO (3.95  $\mu$ mol g<sup>-1</sup> h<sup>-1</sup>), CH<sub>4</sub> (1.50  $\mu$ mol g<sup>-1</sup> h<sup>-1</sup>), and  $H_2$  (4.19 µmol  $g^{-1} h^{-1}$ ) in the photocatalytic reduction of  $CO_2$  in an aqueous suspension under simulated sunlight. The enhanced photocatalytic performance of the nanocomposites was attributed to the beneficial combination of the rGO skeleton, MoS<sub>2</sub> nanosheets, and *in situ* polymerized conductive PPy; this effectively promoted charge transfer, delayed recombination, improved light absorption, and CO<sub>2</sub> adsorption. In summary, this study describes an inexpensive non-noble metal photocatalyst with three components for the efficient photoreduction of CO2 into clean solar fuels.
