Postgraduate offerings

Postgraduate Diploma in Industrial Engineering
FOCUS: DATA SCIENCE

Develop innovative optimisation and machine learning techniques to produce novel, efficient and robust data science technologies, for use in Industrial Engineering, Engineering Management and related applications.

- Structured module-based degree on NQF level 8
- Part-time and full-time study options available
- 8 core modules
- 1/2 year commitment

For more information contact Dr Martina Frei at mfrei@sun.ac.za

Masters in Industrial Engineering
FOCUS: DATA SCIENCE (STRUCTURED)

Develop an in-depth understanding of machine learning models and learn applications in real-world problems.

- Structured module-based degree on NQF level 9
- Part-time and full-time options available
- 8 modules (5 core, 2 electives, and 1 specialisation module) and a research assignment in industry relevant topics.
- 2/3-year commitment

For more information contact Dr Martina Frei at mfrei@sun.ac.za

Masters in Engineering Management
(STRUCTURED)

Educating innovative, future-focused leaders to solve the world's complex sociotechnical challenges.

- The MEM is composed of 7 core modules to enhance engineering and management skills.
- The curriculum can be customized with an elective and special interest research assignment, to support individual professional goals and curiosities.
- Designed with early to mid-career engineers and scientists in mind.
- 2-3 year part-time programme with a hybrid online delivery mode that allows students to study from anywhere in the world.

To find out more send an email to masterseng@sun.ac.za or visit https://mem.sun.ac.za/.

Masters in Industrial Engineering / Masters in Engineering Management
(RESEARCH)

The luxury of two years' dedicated skills development on a topic of your choice, with a topic guru as supervisor.

- Deliverables: 180 credit Thesis and finalized journal paper
- Thesis hand-in due dates:
- End August for December graduation
- Middle November for March graduation
- NQF level 9 qualification
- Full-time or part-time registrations possible

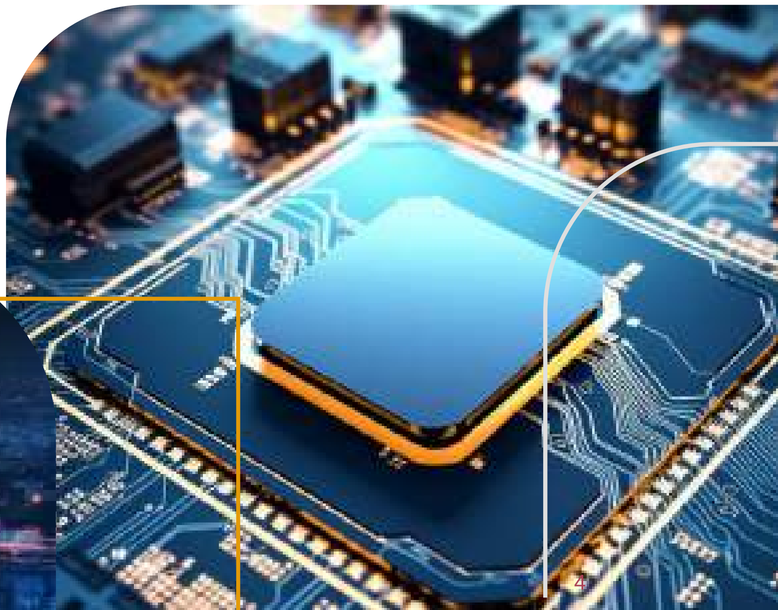
For more information contact Melinda Rust mrust@sun.ac.za

PhD Industrial Engineering and Engineering Management programmes

- Industrial Engineering offerings includes PhD studies.
- Research programme comprising 240 project-work credits in the form of a research dissertation.
- Minimum residency of 2 years.

For more information contact Dr Megan Forster meganforster@sun.ac.za

FIND OUT MORE: www.ie.sun.ac.za



Preface

I am delighted to welcome you to ISEM2023. Some of the older hands in industrial engineering, systems engineering and engineering management may still remember ISEM2011, the first such event jointly organized by SAIIE, INCOSE (SA Chapter) and the University of Pretoria's Graduate School of Technology Management (GSTM) more than a decade ago. This took place at the Spier Wine Estate. With the enthusiasm so prevalent when something new happens it was hoped to organize an ISEM conference every two years. But reality prevailed and it was not to be. Every year following that first ISEM conference "another ISEM" was mooted whenever SAIIE and INCOSE members touched sides. Then, a once in a century global disaster struck. The dark clouds of Covid-19 put paid to any hope repeating the success of ISEM2011. Late one afternoon in November 2021 I received a phone call from Dieter Hartmann now the ISEM2023 Organizing Committee Chair suggesting that we really must do something towards another ISEM. This resulted in an early 2022 meeting, drinking lots of coffee at the dairy farm in Irene - my favourite "business meeting venue" – at which we agreed that the time has come for the next ISEM conference. Now, almost two years later, ISEM2023 is a reality.

In the light of many things happening in our country - good and bad - our theme for ISEM2023 – *be the piece* - is appropriate and fits the immense challenges South Africa face. Especially now that the world is busy building a new puzzle, one in which we all can, and should, play the role of a (puzzle) piece. Incidentally, the early seeds for the ISEM2023 conference theme and logo were planted during another coffee drinking meeting at the dairy farm! (dairy farms have turned out to be truly productive places!).

Back in 2011 ISEM2011 attracted some 120 paper abstracts. For ISEM2023, aware of the fact that the country just emerged from the Covid-19 pandemic and ongoing energy shortages, we hoped to attract at least close to the 100 abstract submissions of ISEM2011. We were pleasantly surprised when, at reaching the abstract deadline, we had 282 abstract submissions! Despite some attrition we still ended with 215 draft full paper submissions. Following a number of withdrawals and a paper review cycle we ended with 146 accepted final papers. These, together with 19 abstract-based presentations, 7 workshops, 1 panel, a number of keynote addresses and social events promise a trendsetting conference!

We invite you to enjoy ISEM2023 in the fairest Cape of them all! And accept the challenge to be a piece in the puzzle!

The submission and review process

For this conference, prospective speakers were invited to submit full papers or abstracts only.

Abstracts for the full-paper track were initially screened based on suitability, with successful authors invited to submit a draft full-length paper. These were reviewed by reviewers from our ISEM2023 Reviewer Panel (121 reviewers), all of whom were carefully selected after an open invitation to experts in the fields of industrial engineering, systems engineering and engineering management. All submitted papers were screened using the Turnitin plagiarism software tool to uphold academic integrity. Submissions that passed this screening process were then reviewed using a double-blind, peer-review process. The review process was managed through an online conference system (Easychair) that allowed reviewers to provide online feedback and recorded all reviewer feedback and editorial decisions taken during the process. All papers were allocated at least two reviewers, often teaming up academics and industry experts to facilitate a true peer-review process. Only papers that passed the peer-review process are published in the conference proceedings. As has become the tradition of SAIIE conferences, the best papers were selected to appear in a special edition of the South African Journal of Industrial Engineering (SAJIE). The selection process of these papers considered reviewer feedback, reviewer ratings and suitability checks by the journal's editor. These conference proceedings contain submissions from 10 of the 11 academic institutions with industrial engineering departments in South Africa. Added to this are 3 institutions who also offer post-graduate programmes in engineering management as well as systems engineering. No institution contributes more than 30% towards the papers published in the proceedings.

A total of 146 full paper submissions were accepted after the peer-review process, by far exceeding the number of conference papers accepted for any previous SAIIE or INCOSE conference. Twenty-four of these papers were selected for the special edition of the journal that will be published separately. As a consequence, these papers were withdrawn from the proceedings. A full list of these papers is included on the next page.

The conference, therefore, has three outputs:

- The ***Conference Event*** This includes an abstract of each paper shared with conference delegates using the online conference app and programme and abstract book. The conference event also includes interactive discussions in parallel sessions, themed by paper topic at the conference.
- The ***Conference Proceedings*** (this document) is an electronic document distributed to all delegates and contains full papers submitted, reviewed and approved for the full paper track. The purpose of the proceedings is to give full open access to the output from the conference. The proceedings are available online via the SAIIE website.
- The **Special Edition of the South African Journal of Industrial Engineering (SAJIE)** will be published in November 2023, honouring the best work submitted to this conference. The Special Edition also contains submissions from other related conferences.

Acknowledgements

To organize a conference as large as this takes many people. It is not possible to name each person but be assured we owe our thanks to each and every one who contributed, no matter how large or small your contribution was – you made a difference. But the following people deserve a special word of thanks:

- Thank you to our authors for sharing your magic with us through this conference. And for truly embedding yourselves as a piece of the puzzle! You make a difference.
- Thank you to our many reviewers whose time, experience and wisdom made a positive contribution to every paper. You truly embody the concept of sharing. Without you it will not be possible for our authors to deliver quality papers.
- Thank you to the sub-editors who administered the review process: Chanel Bisset, Chantelle du Plessis, Hanneke Meijer and Philani Zincume. These four people slaved away behind the scenes for many many hours! Much of your work happened late at night and over weekends. You give true meaning to the word "commitment"!
- Thank you to Chantelle du Plessis for putting together the final conference proceedings and Lynette Pieterse for your tireless administrative support. And of course Teresa Hattingh who always was ready with support and suggestions when needed.
- Thank you to the entire conference organising committee, whose enthusiasm and unwavering standards make the conference what it is.
- And lastly, thank you to Dieter Hartmann who, so long ago, called me to insist it is time for another ISEM, and when the going got tough motivated me to continue amidst late submissions, non-compliance to templates and some reviewers going AWOL! Danke Schön!

I trust that you will find the work presented as part of this conference truly outstanding – welcome to our marvellous engineering world. And remember to be a piece of the puzzle!

Dr Jörg Lalk PrEng

ISEM2023 Editor
September 2023

PIECING TOGETHER the puzzle

Global engineering challenges give birth to innovative solutions. With a postgraduate qualification from the Graduate School of Technology Management (GSTM), you can be the missing piece to complete the puzzle.

GSTM offers internationally recognised postgraduate programmes for practising engineers and scientists at honours, masters and doctoral level. The degree programmes address specific industry needs. A strong focus on research in project management, engineering management as well as in the technology and innovation management groups, ensures local and international relevance.

Degree programmes (part-time and online):

- Masters in Engineering Management (MEM)
- Masters in Project Management (MPM)
- Masters in Technology and Innovation Management (MTIM)
- Honours in Engineering and Technology Management (ETM)
- PhD

Continued education courses and programmes:

- Two-, three- and five-day programmes
- Offerings: in-house, contact and online
- CPD points

Scan the QR code below for more information on our continued education courses and programmes.

UNISA
THE DEPARTMENT OF INDUSTRIAL ENGINEERING

150 YEARS
Reclaiming Africa's Intellectual Futures

About the University of South Africa

Unisa is the largest open distance learning institution in Africa and the longest-standing dedicated distance education university in the world. UNISA enrolls nearly one-third of all South African students. Given our rootedness in South Africa and the African continent, Unisa today can truly claim to be the African university in the service of humanity. UNISA offers an unparalleled range of study choices, ranging from short courses and certificate programmes, to three-and four-year diplomas, advanced diplomas and degrees. It further offers post graduate diplomas, masters and doctoral degrees, with close to 400 000 current students. The Department of Industrial Engineering located within the School of Engineering in the College of Science, Engineering and Technology (CSET) offers a range of undergraduate industrial engineering programmes which are accredited by the Engineering Council of South Africa. The Department of Industrial Engineering also offers post graduate qualifications. The globally respected and widely referenced Times Higher Education (THE) World University Rankings 2023 (www.timeshighereducation.com), which rates over 1700 universities across 104 countries and regions has placed UNISA's Engineering disciplines across the board in joint first place in South Africa. UNISA joins North-West University and Stellenbosch University in the top spot.

About the Department of Industrial Engineering

The Department of Industrial Engineering offers the following flexible and inclusive programmes:

- Diploma in Industrial Engineering (NQF6)
- Advanced Diploma in Industrial Engineering (NQF7)
- Bachelor of Engineering Technology Honours (NQF 8)
- Master of Engineering (MEng) (NQF 9) by research
- Doctor of Philosophy in Engineering (NQF10)

About the Industrial Engineering Profession

The domain of industrial engineering is concerned with the design, installation, and continuous improvement of integrated systems of people, materials, information, equipment, and energy. The discipline draws knowledge and skills in mathematical, physical, and social sciences together with principles and methods of engineering and analysis and design to specify, predict, and assess the outcomes to be attained from such systems.

Research focus in the Department of Industrial Engineering

The research interests in the Department of Industrial Engineering include amongst others:

- Systems Thinking
- Systems Engineering
- System Dynamics
- Lean Manufacturing
- Quality Engineering
- Digital Transformation
- Productivity and Optimization
- Safety Engineering
- Supply Chain Engineering
- Advanced Manufacturing
- Technology Adoption

SAJIE Special Edition Papers

School of Industrial Engineering

Conference

INDUSTRIAL ENGINEERING IS A MULTIDISCIPLINARY FIELD INTEGRATING OTHER ENGINEERING AND SCIENTIFIC DISCIPLINES, WHILE CREATING OPPORTUNITIES FOR COMPETITIVE ADVANTAGE.

AVAILABLE PROGRAMMES:

1. **BEng in Industrial Engineering –**
   - A 4-year, full-time, contact programme that is targeted at undergraduate students who are interested in becoming Industrial engineers.
   - For More information please visit *https://engineering.nwu.ac.za/industrial-engineering*

2. **Postgraduate diploma in Industrial Engineering –**
   - A 2-year, part-time, distance programme that is targeted at individuals who aspire to advance their career or change direction by gaining specialised IE knowledge and skills.
   - For More information please visit *https://engineering.nwu.ac.za/industrial-engineering/postgraduate-diploma-industrial-engineering*

3. **Postgraduate degrees in Industrial Engineering –**
   - Several postgraduate degrees are offered such as MEng in Industrial Engineering, PhD-Eng in Industrial Engineering, and MScEng in Industrial Engineering
   - For more information please visit *https://engineering.nwu.ac.za/industrial-engineering*

UNIVERSITY OF PRETORIA

DEPARTMENT OF INDUSTRIAL AND SYSTEMS ENGINEERING

LEARN

Click to learn more about us

Are you ready to start your postgraduate journey?

WHY CHOOSE THE UNIVERSITY OF PRETORIA?

The University of Pretoria's Department of Industrial and Systems Engineering is an intensive research unit that works towards the integration of contributions from all engineering disciplines into a functional and cost-effective product by using systems knowledge and understanding. The Department's focus areas include:

- Supply chain management
- Enterprise engineering
- Optimisation

WHY ENROLL FOR A POSTGRADUATE QUALIFICATION?

A postgraduate qualification in Industrial and Systems Engineering can develop your ability to identify opportunities to integrate the contributions of various specialists, identify and adapt appropriate technology, and expand your global perspective. In this way, new processes and technology may be developed to solve problems and handle situations that may, at present, be unknown.

OUR POSTGRADUATE DEGREES

- BEngHons Industrial Engineering
- BScHons Applied Science
- MEng Industrial Engineering
- PhD Industrial Engineering

APPLY

Are you ready?

Click to follow the steps in EBIT's Postgraduate Lifecycle

Never stop improving systems and processes. As an Industrial and Systems Engineer with a postgraduate qualification, you will be in the position to not only to improve the systems that you are responsible for, but to enable the best possible solution.

Join our world-class institution.

ABSTRACT

Despite research demonstrating the operational benefits of lowering the number of product offerings, manufacturing companies commonly service markets where customers require a wide range of products with various feature options at unpredictable intervals. While lean manufacturing principles have been recognised as enablers of operational excellence in high-volume manufacturing operations, doubts remain concerning the concepts' application in high-mix, low-volume, make-to-order contexts. This project investigates the applicability of Toyota Production Systems within this manufacturing environment. To be competitive, the company must produce high-quality, low-cost goods that fulfil customer standards with short lead times. Using a qualitative research design with a case study analogy and implementing waste elimination, mistake proofing and pull methods, a production cell increased the percentage of sales delivered on time to the customer by 15%.

Keywords: Toyota Production Systems, lean thinking, customer satisfaction

* Corresponding Author

1 INTRODUCTION AND BACKGROUND

The study was conducted at a company that provides competitive manufacturing solutions to major original equipment manufacturers (OEM)'s and 1st tier suppliers in the South African automotive industry and export markets. A variety of operations are conducted in the company's plant, and they include metal stamping and welding, polymer injection moulding, metalworking, forging, tube bending, synthetic leather stitching, and various surface treatment processes (galvanizing, e-coating, powder coating, wet spray painting), as well as many highly automated assembly processes. The company is currently experiencing major production related problems such high work in progress between the workstations of the e-coating line, inconsistent operation times, frequent machine breakdowns, inconsistent quality of coated products and high overtime cost.

This study was conducted at the e-coating plant and the approach would be to focus on a monthly based study for analysis. A standardized production data collection sheet which is was used to identify problems such as machine breaksdowns, poor productivity on the production line. In order to ensure data validity, physical observations were also conducted.Statistical analysis were also conducted to analyse production related data, including cross tabulation of collected machine downtime data. A cause and effect diagram was used to investigate potential causes of machine downtimes

2 LITERATURE REVIEW

This section of the paper focuses on the literature around the strategies that are commonly used for improving of manufacturing performance and these include the lean philosophy, six sigma, theory of constraints and just in time. These concepts inform some of the recommendations proposed to improve productivity and reduce machine breakdowns.

2.1. The concept of lean manufacturing

The discovery and removal of waste from processes to improve the overall value supplied to the customer are commonly understood principles in the lean methodology. Table 1 depicts the seven wastes as defined by Taiichi Ohno in the Toyota Production System, as well as Liker's definitions in The Toyota Way [1]. High-Mix Low-Volume (HMLV) and Make-to-Order (MTO) manufacturing environments can create a variety of challenges for organisations adopting these principles and removing waste in the production process. HMLV environments must deal with product line cycle time variability as well as increased volatility in demand and delivery dates. An MTO firm, by definition, manufactures solely to client order, but the actual batch size in the customer order can vary significantly. The value stream mapping is particularly complex in MTO businesses due to the enormous number of product lines that must be designed for flow [2]. These variables might make locating and eliminating waste challenging.

Table 1: The 7 Wastes of the Toyota Production System

Waste	Definition
Over-production	Producing ahead of demand
Waiting	Idle for a machine, key inputs, or slack with no deadlines
Transportation	Moving materials or information inefficiently
Over-processing	Performing unnecessary steps in process
Inventory	Excess material, work in process or finished goods

Waste	Definition
Movement	Wasted motion employees perform during work
Defects	Production of defects and correction

Making value-creating steps flow while allowing the client to pull value is risky without expensive inventory. Another operational disadvantage is that the economies of scale associated with bulk ordering are not achieved. According to Biller et al. [3], low-volume commodities usually have poor prediction accuracy, resulting in higher safety stock and higher procurement and shipping costs. All businesses must strike a balance between inventory and service level, but these businesses have a higher percentage of stock keeping units (SKUs) with high prediction error.

Despite the difficulties in implementing lean to the manufacturing process in this setting, there are instances of successful implementations in investigated use cases and useful beginning points to explore for implementation. Mudgal et al. [4], discovered that doing a commonality study based on Bills of Materials (BOMs) and shared sub-processes was beneficial in grouping the various assemblies in an MTO manufacturing environment to comprehend the product families.

Irani [5] categorises classic lean tools based on whether they have proven use cases to decrease waste and increase flow in HMLV contexts. Although Biller et al. [3] does not specifically mention lean methodology, he does highlight two benefits that modular product architecture provides to a production system with a large number of product variations: it requires part standardisation across products to reduce the SKU level.

There are also inventory models that have the ability to reduce inventory waste while still allowing customers to pull value. Most HMLV or MTO firms have stochastic demand at component level, lead times for components are more than zero and the replenishment model is multi-period, indicating that orders can be fulfilled in the next period if there is a backlog. The continuous review policy appears to be more appropriate for this setting than the periodic review model because it ensures item availability at the lowest inventory holding cost level for the items. In general, a continuous review policy improves inventory control since products are tracked instantly during transactions and reordered in optimal quantities only when they reach predetermined reorder points. One significant disadvantage of this strategy is that it can be more expensive to track inventories in real time, although in this case, the organisation already has a system that accomplishes this and procures in the best manner described by this model. As the literature implies, inventory holding costs for HMLV and MTO enterprises can be significant due to fluctuation and service requirements; this type of approach should reduce such costs. There have been studies that showed the usefulness of continuous review policies in organisations facing similar issues, such as an automotive factory with volatile demand and a hospital that provides pharmaceuticals and medical equipment.According to the literature, lean principles and methodologies need care in application, but when used appropriately, they can provide value for organisations functioning in an HMLV and MTO environment.

3 RESEARCH METHODOLOGY

A qualitative approach was used with a case study analogy to gain insight into the daily performance of work using the Gemba walk during working hours. During the Gemba walk, notable observations were recorded, and discussions were held with operators and supervisors to gain an understanding of the current phenomena. These records were critically analysed to identify shortcomings in the process.

Interviews were conducted to gather the necessary information on how the organisation reached its daily production targets. The departmental employees and supervisors were consulted from the beginning of the project, where the aims and objectives of the study were outlined. A sample of 15 operations personnel and five supervisors was consulted on a regular basis to extract the required information on the current performance of the department.

Time study is a work measurement technique used to establish the time necessary to perform a task. Time study was used in this research to find line efficiencies and to determine cycle time and takt time in order to identify bottlenecks in the modification processes. Current processes were analysed to find the root cause of the problems.

Observation through the Gemba walk was used to gather more information and to help identify bottlenecks and areas of improvement, and to gain a better understanding of the processes while engaging with those who do the actual job.

A process flowchart is used in a variety of industries to analyse, create, document and manage a process or programme [6]. In this project, the process flowchart was used to evaluate the movement of the elements of each fitment.

Control charts are used to evaluate a process and to check if the process is stable or needs intervention. These charts are achieved using statistical process control, which is a quantitative approach, or analysing data. An X-bar chart is used to evaluate the averages in order to identify problems relating to the stability of a process to avoid assembling defective products. A cause and effect diagram was used in this study to identify the root cause of the problems faced in the organisation.

4 RESULTS AND DISCUSSION

The data analysis process summarises the information gathered. It entails the use of analytical and logical reasoning to data in order to identify patterns, correlations and trends. In order to provide value to customers, obtain a competitive edge and grow, the company attempted to enhance material and information flows to achieve operational excellence. This project examined numerous aspects of the organisation's operations using Lean concepts, with the ultimate goal of increasing responsiveness to its customers. The key mechanisms for achieving this goal were as follows:

4.1. Lead times for components

Lead times in days ranged from 0 to 60 for these items at the plant for the 12 months ending in May 2022. Customers' expectations of lead times can vary due to variances in the quality of engineering or design that an order requires, the uniqueness of components contained in the product or the perceived differences in assembly hours. This truth has a couple of ramifications for how the production team operates. First, when the customer demand rate is not reasonably steady, it is exceedingly difficult for the organisation to use lean approaches derived from takt time analysis. Furthermore, one can imagine a scenario in which orders with customer lead times of 7, 14 and 21 days all result in the same needed date by the customer, placing a burden on the ability to deliver. Given these circumstances, the organisation can maintain client flexibility by reducing processing times per product.

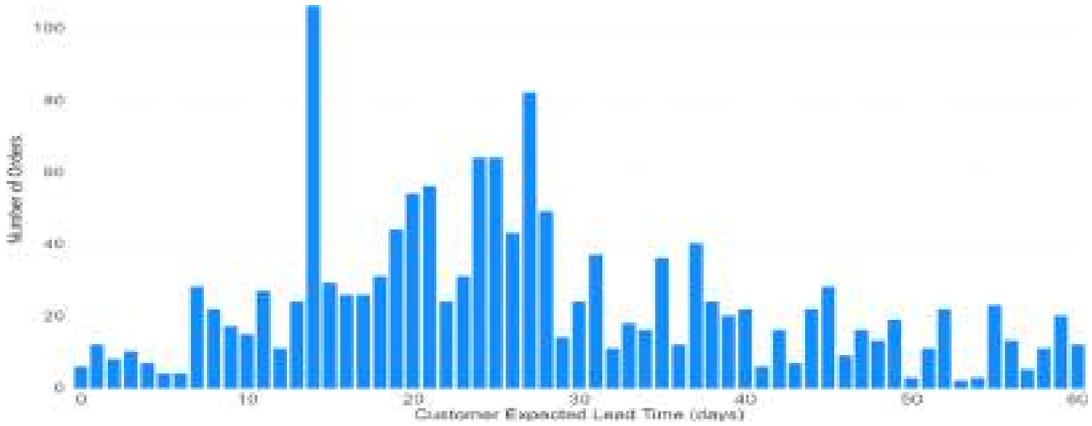

Figure 1: Number of orders by customer expected lead time in days, June 2021 – May 2022, limited to 60

4.2. Commonality based on BOMs

The first step in specifying the product lines is to perform a commonality analysis utilising the BOM data from the client specifications and the business system. Table 2 displays the number of possible product codes and filter housings, as well as the assembled products and unique product codes ordered in the 12 months before 1 June 2022, to offer context for the product diversity and low volume.

Table 2: Characteristics of the product variation and volumes within production cell. The volume and unique codes ordered are from June 2021 – May 2022

Item	Number
Possible product codes	Z212
Possible filter housings	15
Production volume	426
Unique product codes ordered	70

Thirteen of the 15 available filter housings in the customers' design were ordered in the same 12-month period. This mix, as proposed, allowed the classification of the various filter housings as runners, repeaters and strangers, with the actual occurrence of the filter housings among orders given. Upon evaluation of the production steps of the product families, it was discovered that almost 70% of the volume came from four of the top five filter housings that follow similar processes. This helps to appreciate both the mix and the opportunity to focus on efforts to improve.

Two separate pairs of filter housings belong to the same product family because their configurations are identical and safe for the filter housing; however, one filter housing is limited by component size requirements. Aside from the filter housing, the number of available combinations varies by product family, based on the configurations required for system integration. Figure 2 displays the possible configuration choices that allow end customers to choose from hundreds of product codes as an example of how the product family can vary.

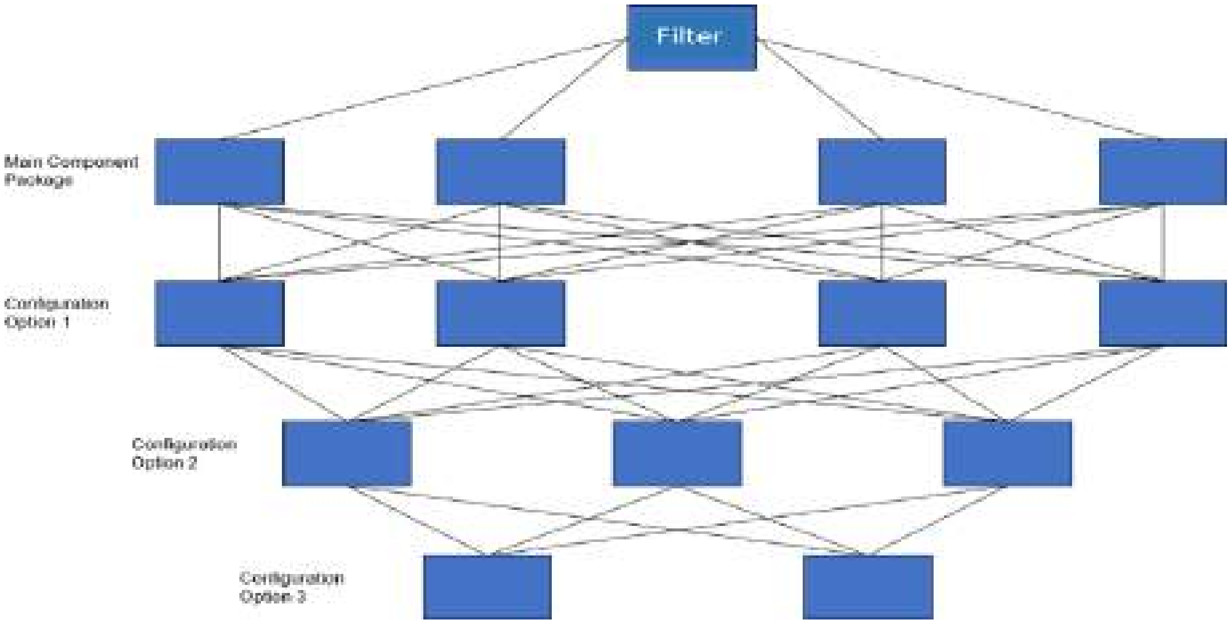

Figure 2: Configuration options for one product family that has 96 end product codes

Upon reflection, it was reassuring to see that of the 13 product families, three accounted for 68% of the volume and ten accounted for 88% of the volume. This depiction of actual production data assisted team members to understand the relative value of the various families in addition to their most recent experience. It also showed that, while variety occurred in the Z212 end product assemblies, genuine variation was less common since certain families were far more popular than others.

4.2.1. Visualising Order Flow

As an MTO company, the organisation provides a product in the form of an assembled filter. This section maps the process flow diagrams connected with the order and product status changes from order receipt to shipment.

4.2.2. Process Flow Diagrams

The organisation combines many of its processes through its business system and has adapted the business system to improve visibility of production progress in addition to the usual order processing. The results show that the flow of the business system standard "order status" processing at a high level. The diagram shows that the majority of the information required to understand the operational procedures is contained in the "Pending Fulfilment" stage, where production takes place [7].

The order is sent to the manufacturing team via the business system, the product is assembled and dispatched, and the sales staff update the business system to reflect the shipment and invoice issuing. The manufacturing process is depicted with the customised "work status" stages.

The business system did not prevent the user from changing the employment status from one status to another; therefore, the paths were the most typical paths based on conversations with employees and observations. In addition, some of these stages could be skipped. Some production cells, for example, employed "New Order" and "Need to Assemble" to sort visibility on forthcoming orders, while others began with "Need to Print Pick Ticket" and progressed immediately from "Parts Pulled" to "In Assembly." Overall, updating an order's job status created a shared understanding among employees across the organisation. It is also worth noting that five of the nine stages that reflect a deviation from the optimum path are related to parts shortages. Because the organisation designated this list of stages, one can deduce that parts availability was a likely source of frustration for the manufacturing crew.

4.3. Production Process Mining

Figure 3 was generated as a preliminary pass to comprehend the quantity of orders that are "In Assembly Waiting for Parts" and "In Assembly" at each window. Figure 3 shows how, at various points, particularly in 2022, orders in production began to encounter increased interruption due to missing parts

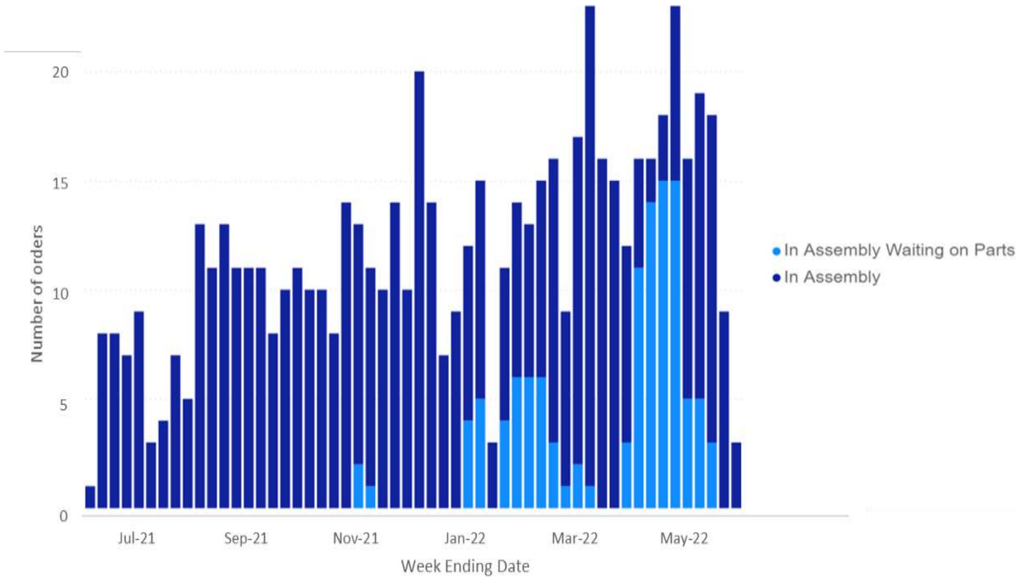

Figure 3: Comparison of quantity of orders in assembly with quantity of orders in assembly waiting on parts, June 2021 – May 2022

Because there were so many distinct end product assemblies that were offered at varying prices, it was critical to assess whether the impacted orders were reflective of the total mix, as opposed to solely affecting orders of lower or higher price. To do this, a ratio indicator that compares the number or value of impacted orders to the total number or value of orders at this point was implemented.

Equation 1 represents this measure.

$$Waiting\ Ratio = \frac{Order\ in\ assembly\ waiting}{Orders\ in\ assembly\ waiting + Orders\ in\ assembly} \quad (1)$$

Figure 4 depicts this ratio in terms of both order quantity and order sales amount. Parts shortages clearly affected sales order amounts, or revenue to be gained, with the same frequency as sales order quantity.

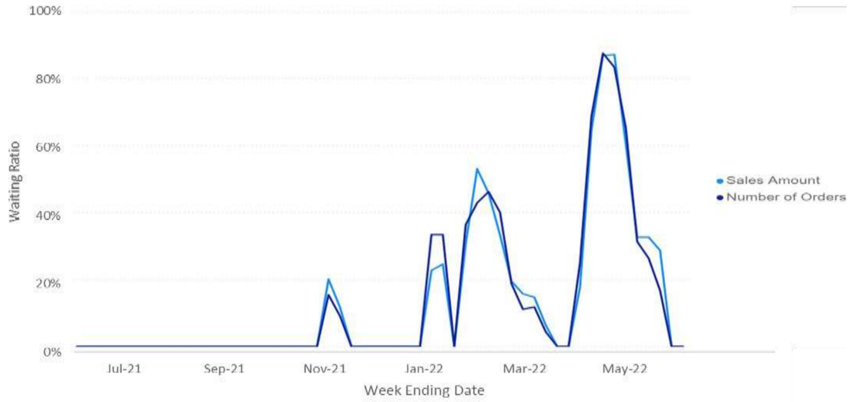

Figure 4: Waiting ratios of quantity of orders and sales amount of orders, June 2021 - May 2022

These numbers indicate that it is difficult to have the proper parts accessible for assembly when needed. Parts shortages have on impact on delivery performance.

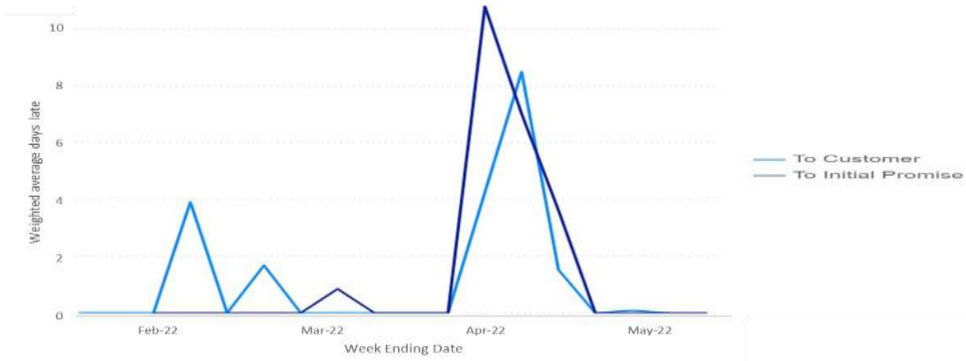

Figure 5: Weighted average days late to want and to initial promise, February - May 2022

4.4. Visualising Material Flow

The spaghetti diagram is a handy tool for visualising how materials move through a manufacturing facility as they are changed from raw ingredients to final goods. In this situation, it will provide a general overview of the material placements within the facility as well as the first steps towards identifying transportation or movement wastes. The spaghetti diagram in Figure 6 uses red lines to indicate the movement of the parts in final assembly.

The cell arrangement within the huge panel assembly area is intended to support U-shaped product flow. Several product families require the installation of components weighing more than 500 kg in the filter housing; therefore, racks of the required sizes are available to allow the rotation and bracing of filter housings, and a top-running crane is used to safely transport heavy goods within the crane area [7].

Estimates of the distance spent on material movement are done by taking into account the fact that these movements require round trips for team members to move to and from the location with material, estimating the number of trips required during production of each product from runner or repeater families, and measuring the distance involved in the movement. Table 3 indicates the results from applying this strategy to the material movements.

It is also crucial to evaluate how the material is stored in the facility and how it is transferred, in addition to where it is stored. Based on the feedback from team members and personal experience, it was discovered that the filter housings, their accompanying pieces and panels, and two of the bigger internal components caused problems for the warehouse team and production cell [8].

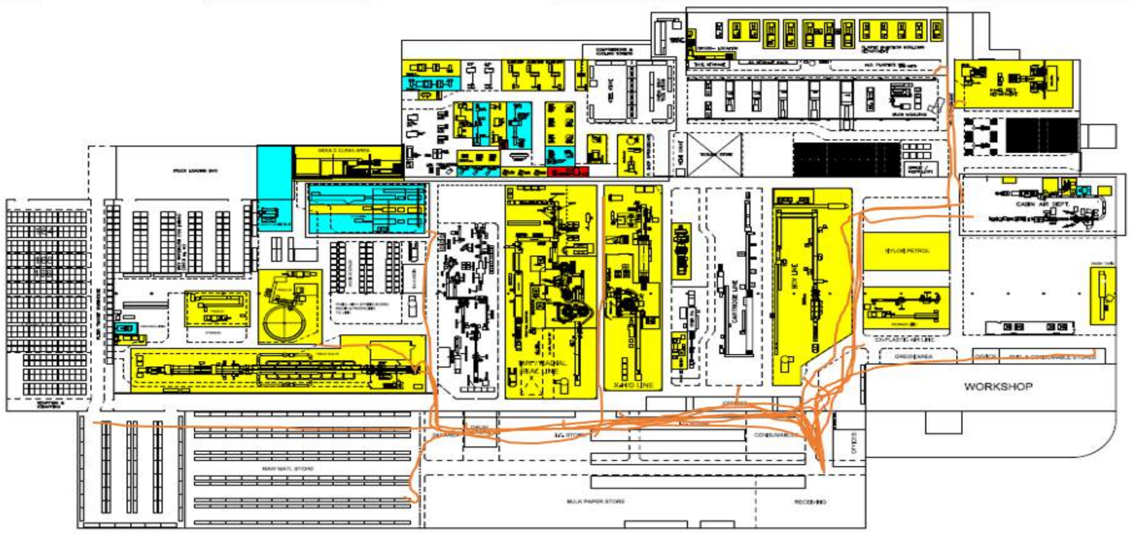

Figure 6: Spaghetti diagram of material movements within the factory

Table 3: Current state of material transportation and employee movement distances for various components common to products from runner and repeater families

Material	Per Product	Distance [m]	Total [m]
Cans	1	150	300
Seals	2	185	740
Washers	1	185	370
Element assembly	1	175	350
Centre tube	1	50	100
End caps	2	220	880
Media	1	40	800
Labels	1	80	160

4.5. Picking, Sub Assembly Production, Testing, and Shipping

The next step in the fulfilment process is to pick the order and gather the necessary components for assembly. Employees from the warehousing department carried out this action after obtaining a picking ticket from the manufacturing cell's team leader. All of the required smaller components were loaded onto a cart, labelled with the matching order information and a status form, and staged in allocated open space in the warehouse room until carried to the assembly area by a member of the production cell. Larger components housed in the storage bay or outside were fetched immediately by production cell members when needed for the order.

Four of the seven product families that were runners or repeaters necessitated the creation of sub-assemblies in different portions of the facility. If a sub-assembly was necessary for an order, the business system created a work order, and the production cell team leader filed a picking ticket to the warehouse section to gather those components. Team members who built the sub-assembly drew the staged cart and assembled the sub-assembly in their work locations. The sub-assembly work for this production cell mostly consisted of cables and smaller filters that were later placed into the bigger filter. Team members from the production cell would pull these sub-assemblies for installation as needed when finishing the final assembly [9].

The final product assemblies were tested for safety and quality by the production cell team leader. When an assembling team member finished the product they were working on, they would transport it to the testing part of the cell so they could start working on the next order. The Quality Management System classified problems into four basic categories: Wiring failures occur when components are not properly connected; connections fail when terminal connections are not secure; component failures occur when incorrect components are used within the product; and label failures occur when labels fail to reflect correct panel ratings or information about the product or components within the product. The team leader offered input on any problems discovered to the team member who assembled the product so that it might be corrected in future for that product and similar items. The quality system used a variety of measures, including panel first pass yield and defect kinds. Figure 7 depicts the production cell assembly error type per month [10].

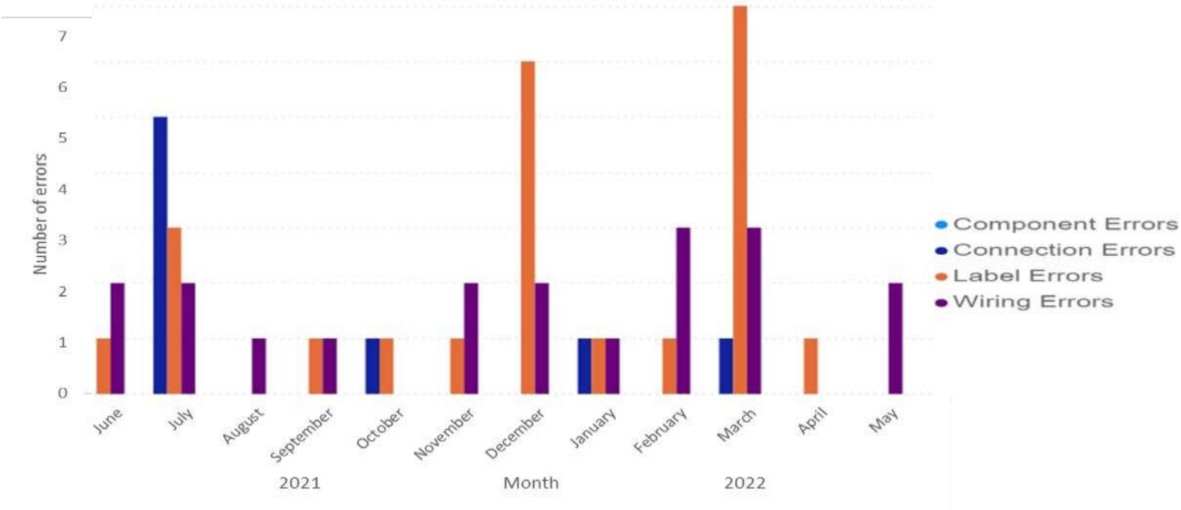

Figure 7: Breakdown of production cell assembly error type per month, June 2021 - May 2022

5 RECOMMENDATION AND CONCLUSION

This research revealed the complexity of the processes involved in the filter industry. Lessons about which strategies are effective as well as the limitations of the methods that the organisation can use were revealed in this investigation.

5.1. Theme 1 - standardisation

The first theme that can be effective across the multiple dimensions of product manufacture was standardising the products and processes as much as is feasible. This enabled the discussion and execution of standard work, reduced time spent due to seeking and enhanced team members' perceptions of operational processes and interactions.

The modular design offered by suppliers was one of the most effective techniques of enabling flexibility and pooling volatility in demand. This decreased the need to handle each order based on its unique requirements rather than a set of known requirements, allowing for advances in capacity and quality. According to the research literature, the supply chain was easier to manage when the parts were shared across multiple product versions.

5.2. Theme 2 – improved service

Improved service levels were experienced by internal and external customers while reducing inventory levels for numerous items with higher holding costs by learning how to extract data linked to lead times and demand and implementing the continuous review inventory replenishment policy. The results show that such a model may be effective in this environment despite the complexity of SKUs and demand.

5.3. Theme 3 – improved information flow

Efforts to improve information flow centred on enhancing access to the information required each team member to make choices and create redundancy in the communication that already occurred between team members. The greater understanding of how their actions affected the value stream boosted team members' skills to make individual judgments that were more helpful to the entire system. These advancements were also aimed at leveraging the business system as the one source of truth, so that each team member could relate to the issue from the same contextual perspective [11].

5.4. Theme 4 – automation

Team members appreciated the relatively basic automation created for the quality it ensured, the annoyance it alleviated and the capacity it added to the operations. The key to this automation was that it was not limited to specific use cases but could be applied to any product variation experienced by the team members. As a result, rather than being regarded as a step with significant setup costs and limited impact, it could become ordinary and standard.

Using data from the business system in process mining assisted in visualising the steps of the manufacturing process and alleviating the shortage of data surrounding the manufacturing processes. This was a workaround, but it might be used in conjunction with a system to track actual production times to better evaluate operational performance.

5.5. Theme 5 - groupings

The whole menu of product variations was understood and characterised by product codes and groupings, which was a vital condition for the deployment of many of the initiatives that enhanced efficiency. This enabled one to structure the analysis around product families, collect and categorise usage data, take advantage of modular design opportunities and automate numerous phases in the process. None of these efficiencies could be reached without product codes or a complete grasp of the number of different configurations, what they have in common or how they differ and what the product family groupings are.

5.6. Theme 6 – data integrity

The inability to track actual production times using business system data and the data integrity underlying the analysis limit the use of the process data analytics. Understanding the lead time or demand characteristics at the SKU location level would have been impossible if the business system had not been a trustworthy source of data for how components flowed in and out of the plant. Further examination of operational performance would be possible if there is continuance to refine which metrics are tracked and how data are recorded.

5.7. Theme 7 - investing in fixture or production automation

Clarifying the influence of machine automation investment on various steps of this manufacturing process is one area for future investigation. Because of the variance and confined places in which most of the assembly happens, the existing method is highly human, and there are several constraints to using fixture automation in this setting. This application potential will expand as robotic technology progresses and machine manufacturers continue to create and produce adaptable solutions. There are only a few case studies involving the effective deployment of machine tools in this type of HMLV and MTO setting with these production restrictions, and this research might benefit from them.

5.8. Theme 8 - information architecture

This study provides basic insights into how data processing can be used to create information architecture for individual team member decision making. There is more opportunity to investigate the implications of ideal information architecture for enterprises manufacturing in this environment and utilising approaches such as Industry 4.0. The applicability of establishing an information architecture throughout the production processes, like other decisions requiring investment in this technology, depends on how effectively the development will handle the mix and volume.

5.9. Theme 9 - replenishment model refinement

The supply chain modelling research revealed the early promise of the continuous review policy in an HMLV and MTO environment, but there is still room to learn about the following stages of supply chain evolution. Aside from simply applying the models presented in a more systematic manner throughout the organisation, there is a strong possibility that one could continue to improve performance at a lower cost by conducting a multi-echelon inventory optimisation analysis within the facility and treating on hand and available inventory as separate demand stages with different characterisations. Additional research into the appropriate length of historical demand to consider in the model best suited for this environment may be conducted [12].

ABSTRACT

The optimization of supply chain processes in the e-commerce retail food distribution environment is critical as it assists in ensuring optimal costs and profit for the companies. Furthermore, identification of bottlenecks ensures that any issues related to meeting customer orders and on time delivery. The increase in demand for doorstep delivery led to an increase e-commerce activity. This study was conducted at organization that had launched in South Africa to meet the increased demand for online shopping. The company experienced frequent complaints related to large quantities of stock being sent back to distribution centers, especially perishable goods such as fruits and vegetables and dairy products. These complaints include stale products, late orders, wrong orders. The cost implications of this have been very high as these products have had to be disposed of due to their low shelf life. The organization concerned is mainly a grocery retail store that delivers basic groceries and basic medication. A qualitative methodology in the form of a case study was employed for the study. The results of the study benefitted the organization in the form of improvements in process capability, brand loyalty, waste reduction and the management of products.

Keywords: optimisation, supply chain optimisation, e-commerce

1. INTRODUCTION AND BACKGROUND

E-commerce can defined as the electronic process by which individuals or organisations buy, sell, transfer or exchange products, services and/or information and it effectively eliminates the need for large investments or outlays on physical infrastructure to develop a global presence, resulting in a revolution in the way in which business is conducted globally [1]. In this sense, e-commerce not only automates the transaction process by eliminating paper and unnecessary steps but also assists in moving organisations into a more efficient manner of operation by going fully electronic and utilising internet of things tools.

The research study was conducted in a start-up tech business in the South African market aimed at meeting the demand of people needing faster delivery services of their orders on essential groceries, fresh produce, medication, and more. The company originally established in one of the developing countries in Asia as a response to the high demand of people needing essentials delivered to their doorstep during the COVID19 pandemic. The company was very successful in its home state and therefore, decided to branch into other markets, which led the company to South Africa. The South African launch was successful, and it saw the company contribute to reducing the unemployment problem faced in the country by employing over 200 South African citizens and going into business partnerships with freelancers and delivery personnel.

The company experienced frequent complaints related to large quantities of stock being sent back to distribution centers, especially perishable goods such as fruits and vegetables and dairy products. These complaints include stale products, late orders, wrong orders. The cost implications of this have been very high as these products have had to be disposed of due to their low shelf life. Various issues ranging from incorrect stock management practices, inventory management at distribution centres, and the incorrect handling of perishable goods (fruits and vegetables) and other customer complaints that have negatively impacted the organization.

The large quantities of stock are being sent to back to the company distribution centres, especially perishable goods such as fruits and vegetables and dairy products. The cost implications of this have been very high as these products have had to be disposed of due to their low shelf life. Figure 1 chart shows a summary of the frequent customer complaints that the business is faced with.

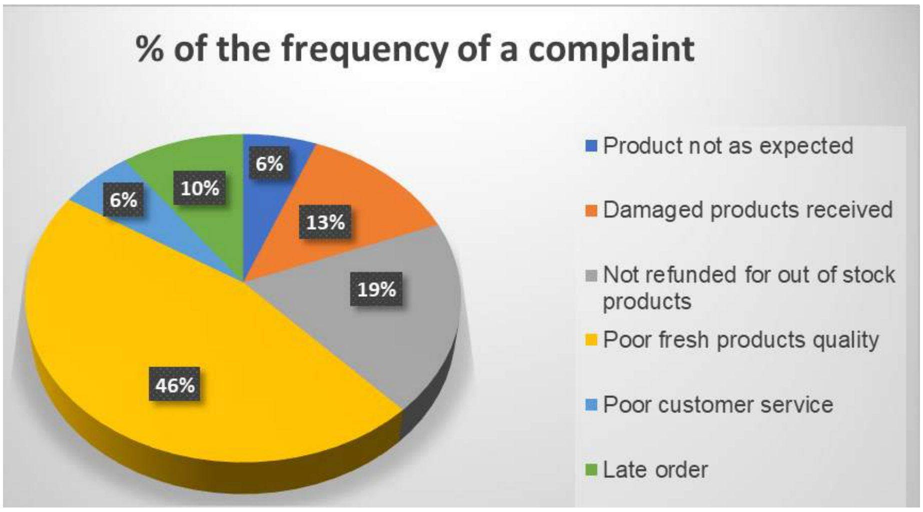

Figure 1: Most frequent customer complaints.

The study was aimed at developing an efficient optimized supply chain process in the e-commerce space and good inventory management practices that will result in businesses providing good and quality customer service. The study objectives include

- Developing a good stock management strategy for an E-commerce tech business to improve product quality.
- improving customer management practices to increase the number of loyal customers.
- reducing management costs

The study is significant because it would be of great benefit to the E-commerce businesses that are being launched in the following ways:

- It will help start-up businesses develop efficient inventory management standard operating procedures.
- It will help start-up businesses in this field determine the most important key performance areas, and how to ensure they excel in them to build a loyal customer base that trusts them.
- It will shed light on the state of the e-commerce business in South Africa and the South African online buyer's behaviour.

Furthermore, this research will help organisations offer customers shorter lead times and lower inventory costs because of optimized processes and improve on-time availability of stock.

2. LITERATURE REVIEW

This section covers the literature around supply chain, inventory management, electronic data interchange, product availability and last mile delivery.

2.1. Importance of supply chain and inventory management

To ensure the efficiency of an e-commerce business, its supply chain processes must be optimised and this can result in enterprises achieving smooth, real-time supply chain integration with a competitive edge [2]. Therefore, the e-commerce applications must be multi-layered and feature rapid decision-making to achieve real-time efficiency. Furthermore, versatile processes with high service levels should be fully linked to the international supply chain. Importantly, processes by which online retailers can achieve higher inventory turnover and just-in-time delivery practices is inventory management. In e-commerce, flexible systems that respond to customer demand and inventory uncertainty are critical [3].

2.2. Inventory management and order fulfilment strategies

Inventory management is a methodical approach to acquiring, storing and selling stock, which includes both raw materials (components) and finished goods. It means the right stock, at the right levels, in the right place, at the right time and at the right cost and price. Inventory management, as part of an organisation's supply chain, consists of elements such as controlling and overseeing purchases (from suppliers and customers), maintaining stock storage, controlling the number of products for sale and ensuring order fulfilment [4].

The primary goal of inventory management in a business is to monitor stock levels so that the business can balance the number of products without running out of stock or ordering products in excess. This is the most effective way to maintain profits while reducing retail waste [5]. The essential elements of inventory management are discussed next.

2.2.1. Traceability

It is very important for business owners to be aware of changes in the movement of their organisations' inventory, from product transfers to inventory losses such as damaged goods or missing products, so that when the time comes, they are in control of matters rather than overwhelmed by irregularities. It is also critical for a business to have detailed inventory management reports organised in one location. Collecting inventory data is important for determining areas for improvement. Therefore, it is essential to record all information available in order to optimise processes.

2.2.2. Stocktakes

Cycle counting is a check-and-balance method used by businesses to ensure that physical inventory counts match inventory records and entails performing regular counts, recording specific product adjustments, and have counted all of their possessions over time [6]. The purpose of cycle counting can then be summarised as identification and correcting any discrepancies in inventory records.

2.2.3. Out-of-stock products

Assisted by detailed cycle count, accurate demand forecast , an organisation may be able to identify which products are missing and which are selling the most, assisting with the determination of the reorder point for stock. This element of inventory management allows businesses to act quickly to remove out-of-stock products from e-commerce platforms, ensuring that they do not sell products that are not available.

2.2.4. Product identification and description

A major part of inventory management is being organised. Businesses should keep clear and informative descriptions, for example, names, sizes and colours, of their products. Without this detailed information, businesses will not be able to fully understand their reports and see the total picture. All products should be clearly labelled or marked so that the products can be identified at a quick glance. This aspect is vital for speeding up fulfilment processes, as well as making sure no mistakes are made when it comes to stock counts.

2.2.5. Storage space

A clean, spacious and well-kept work environment will help to limit the amount of time spent looking for products. According to research, such a work environment may improve the effectiveness of a business and its employees. If the storage or warehousing space of a business is not already well organised, it would be worthwhile to devote time to improving inventory management. There are no flaws in doing so, only pure profit.

2.3. Last-mile delivery

Last mile delivery includes all the activities required for the consumer to receive the items purchased. The last mile is the only point of contact between a customer and a company. The front door has evolved into the new marketplace. Giving shoppers what they want is essential, but providing a consistent experience from order to delivery has become the golden standard for retailers worldwide. Last-mile delivery is an important part of providing a world-class brand experience and keeping customers loyal to a brand. In the last mile, the consequences of poor service are incredibly high. Positive last-mile interaction leads to increased brand equity and loyalty. Last-mile delivery has several cost implications, which include the following:

- Last-mile delivery is estimated to account for 53% of the total cost of moving a product over the first, middle and last miles in delivering it to a customer [7].
- Returns are costly for retailers, especially when one considers the initial delivery cost as well as the return logistics. In addition, some orders that are returned must be reduced in price in order to be resold.

- Given that consumers demand fast and free delivery, online retailers must contend that “free to consumers” does not imply “free to the business”. To keep customers coming back, brands need to absorb delivery costs.

2.4. The last-mile logistical challenges in e-commerce

The final step in the delivery process is logistics. When a customer places an order, the last mile begins. The brand or logistics provider collects and prepares the order for delivery before delivering it to the customer via the method selected [8]. the following last-mile logistical challenges are commonly experienced by online retailers: order picking, order fulfilment and inventory strategies, last-mile delivery strategies, reverse logistics and delivery service quality. Most major retailers have storage facilities that are solely devoted to fulfilling online orders. The first step in ensuring that a customer's order is filled is order fulfilment process [9].

2.4.1. Order preparation and picking

Inventory management entails managing stock-keeping units (SKUs) in such a way that an online retailer can fulfil online orders in advance of consumer demand, which can be easy for dependent demand but difficult for independent demand. The main challenges that are encountered in order preparation and picking are as follows:

2.4.2. Substitution

Substitution entails having a variety of options that customers can pick from in case the items they want are out of stock. This is one of the biggest challenges most South African online grocery stores and omnichannel retailers face because, in such instances, the pickers do not know what items the customers would prefer as replacements. Start-ups, in particular, do not have the resources to have substitution built into the back end of their online applications. Methods of order picking can range from manual in-store picking to fully automated picking processes. Picking processes have significantly improved over time because of automated replenishment methods, improved order preparation methods and optimal vehicle utilisation [9].

2.4.3. Sensory quality

Sensory quality pertains to the quality of products that is difficult for consumers to evaluate online, particularly in the case of perishable food items that must be refrigerated. Groceries are touchable and perishable items, making the online evaluation of items, particularly items that are not enclosed in product packaging, more difficult.

Customers are generally sceptical of a retailer's ability to choose the best quality on their behalf. Grocery purchases involve physical interaction with products, implying that people would prefer to check the condition of items before purchasing them. It is thus clear that a big disadvantage of e-commerce entities that sell groceries is that they limit the sensory observation of products [9].

2.4.4. Order fulfilment

To be competitive in the e-commerce industry, it is important for an organisation to determine the methods of order fulfilment that will best suit its business structure. The products and the services that the organisation will sell to the public represent the main factor that will determine the best techniques to use.

The geographical market is another important factor to take into consideration in determining which order fulfilment methods to use. Online grocery retailers can use distribution centres and existing stores, partner with traditional grocers or offer a pick-up service to deliver products to customers. To achieve fulfilment, omnichannel retailers use a variety of strategies; however, food retailers tend to structure fulfilment and last-mile activities in-house, whereas non-food retailers are more likely to collaborate with external logistics providers.

2.5. Quality Management in the food retailing supply chains

2.5.1. The cold chain and customer expectations

Online retailers need to ensure that they meet the requirements of cold chain distribution, and that cold stock gets delivered to customers in a good and condition. Customers are frustrated and unhappy when they have to wait long before being served. Customers prefer a service that is flexible, on time , with correct quantities, reliable and customer-service orientated.

2.6. Reverse logistics

Among the main challenges that online grocery retailers face in the food industry is product return. Owing to the perishable nature of food products, they have expiry dates and require quick and effective distribution operations. Because of the unique characteristics and the perishability of certain grocery products, coupled with difficulty in tracking non-barcoded products, reverse logistics is extremely difficult. Product returns in an online food supply chain are even more complicated because it is simply not profitable for online grocery retailers to incur additional costs to collect food items that cannot be reused.

2.7. Electronic Data Interchange

Organisations use electronic data interchange (EDI) to bring trade online and this entails using computer technology to exchange information (or data) electronically [10]. EDI optimises the efficiency of a business by streamlining processes and improving the flow of information within the organisation. The advantages of implementing EDI in a business include:

- Reduced operating costs owing to the elimination of manual activities and unnecessary or non-value-adding processes
- Improved efficiency owing to streamlined processes
- Improved accuracy
- Greater visibility of supply chain activities
- Improved security of the organisation’s intellectual property
- Better business management processes

In EDI, data are structured according to a particular configuration that is recognised by both exchangers, allowing computers to exchange relevant information without human involvement or the need to re-enter details at both ends of the path [11]. The main components of EDI are:

2.7.1. Standards of EDI

EDI standards offer ways of encoding data to facilitate electronic transmissions. The exchange of electronic documents or data takes place in a ready-made format agreed upon by the two parties to the transaction. Great efforts have been made to develop such standards at the international level.

2.7.2. The software for EDI

The primary function of EDI software is to convert and format data and to send messages. A practical program is one of the most important and fundamental infrastructures for electronic commerce [11].

2.8. EDI Communication services

Communication services send and receive transmission files from and to trading partners directly or through a value-added network (VAN) [12]. A VAN is a telecommunications network that is primarily intended for data transmission but also processes data; as a result, the network provides services that go beyond simple data transmission [11].

2.9. Types of e-commerce businesses and EDI

E-commerce businesses can be categorised into different types based on the type of relationship between different sides of commerce [13]. The types of e-commerce businesses are as follows:

Table 1: Types of businesses in the e-commerce space

Type of e-commerce business	Description
Business-to-business (B2B)	Manufacturers that sell to distributors and wholesalers that sell to retailers are examples of companies that do business with one another. Pricing is determined by the number of orders placed and is, in many instances, negotiable.
Business-to-consumer (B2C)	Businesses that sell to the public fall in this category. They use catalogues and shopping cart software.
Consumer-to-business (C2B)	In the case of C2B, consumers post their work online with a set budget, and companies review the consumers' requirements and bid on the projects within hours.
Consumer-to-consumer (C2C)	In the case of C2C, customers make use of sites offering free classifications, auctions and forums where individuals can buy and sell their products.

3. RESULTS AND FINDINGS FROM THE STUDY

The results obtained using the method specified in the previous section are presented in this section. The first part of the findings deals with data obtained from historic company performance reviews. It dissects the company's order fulfilment process in relation to its efficiency and its contribution to cost implications in respect of product disposals owing to poor stock management. The second part of the findings focuses on the observations made by the researcher. The researcher made observations on stock management and reporting, the management of perishable goods, the training of employees and the utilisation of standard operating procedures (SOPs). The third part of the findings reviews the performance of the business in terms of customer management and the number of complaints received. This section also identifies and discusses the different types of service failures within last-mile delivery. It quantifies the data with a view to giving insight into the effectiveness of the relevant department and identifying opportunities for improvement. The fourth part of the findings relates to the results from the researcher's interviews and group discussions with the different members of the team.

3.1. Inventory Management – Performance Reviews

3.1.1. Order fulfilment

Data were collected regarding the amount of stock received by one of the organisation's 13 local distribution centres located in the north of Johannesburg, Gauteng, South Africa. The specific distribution centre (DC) services areas such as Sandton and Rosebank. Figure 2 indicates the amount of stock the DC received as against the amount of stock that was disposed on the same day, demonstrating the typically happens within the organisation's DCs on a daily basis. Almost all the stock that is received back to the distribution centre is disposed as it has reached its end of life.

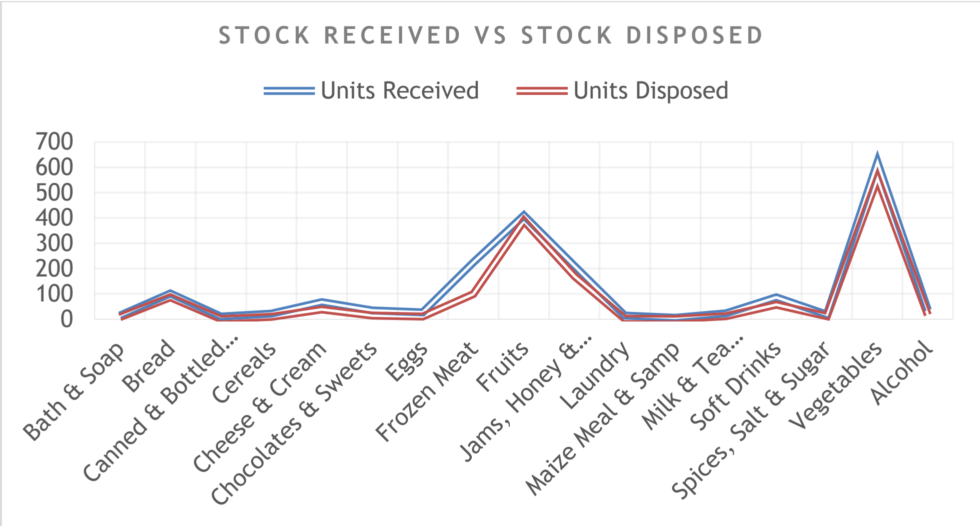

Figure 2: ***Stock received vs stock disposed at a certain distribution centre in Johannesburg***

Having either too much or too little inventory leads to a waste of money. Whether a business does not order enough stock or overorders stock, it could place itself in financial jeopardy if it does not have the right amount of inventory [14]. The pie chart below is a direct representation of the cost implications of the above-mentioned disposals at the DC.

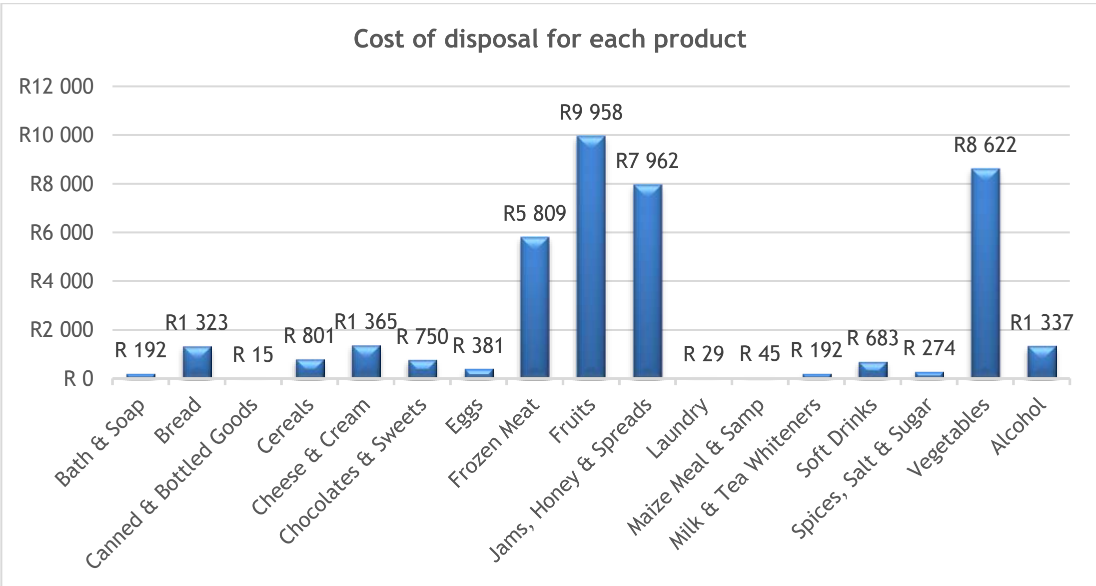

Figure 3: The cost implications of disposals

3.2. The Researcher's Observations

3.2.1. Inadequate stock-on-hand/out-of-stock report

The organisation has an enterprise resource planning (ERP) system that can be used to download stock data, but the report does not show exactly what each DC requires. Consequently, a lot of manual work is required. Supervisors and managers must, for example, indicate what products are needed at the DCs, what products they sell the most of and what new variations of certain products they need. As a result of so much manual work, human errors occur, leading to unnecessary stock being sent to distribution centres. Such stock takes up space and represents a waste since it is unutilised inventory.

3.2.2. Manual addition of stock to the ERP system

This practice is the result of every shipment being sent to distribution centres that have extra items that are not included in the systematic purchase orders used to receive the items. When stock is sent from the central mid-fulfilment centre, that centre is supposed to create purchase orders for all the DCs to use when checking in the stock. This procedure promotes the traceability of, and accountability for, each item checked into a DC. However, owing to the manual activities that the organisation performs, the mid-fulfilment centre ends up adding items that are not on the purchase orders and ships them to the distribution centres. The distribution centres are then required to check in these items ad hoc. Items checked in ad hoc are problematic because it is difficult to investigate an item that does not have a purchase order or any form of documentation as to why it is in the warehouse.

3.2.3. Management of perishable goods (fruit and vegetables)

The management of fruit and vegetables is an area that requires improvement and continuous monitoring. As per the data provided above, fruit and vegetables account for the largest portion of losses that occur as a result of disposals. It was observed that perishable items are not stored in the correct way at the DC. Fruit and vegetables are kept in a very cold area, which results in them rotting within the first two to three days of their arrival at the DC.

3.3. Training of employees

The warehouse operators require continuous refresher courses owing to regular system updates, the behaviour of employees and how quick they are to grasp new concepts.

3.3.1. Interviews with store managers and live operation leads

Store managers and live operation leads were interviewed to determine their views of the organisation's operations and policies. The main findings of the interview sessions are as follows:

- Platform integrity issues with the customer app vs the picker (dark store) are not coordinated for some products. As a result, the wrong items are picked for customers in some cases. This situation leads to increased operational costs at the warehouses because customers must either be credited or provided with exchanged items.
- The riders lack customer service etiquette, which leads to customers having unpleasant experiences in the last mile of delivery. This aspect directly contributes to whether a client will return to the business or not.
- Most of the riders are demotivated because they believe the income they split with the company is not a good deal. This leads to them not being on their best behaviour when they make deliveries, which harms the company's reputation directly. They would like a tip option added to the organisation's app.

- The training of store operators is not sufficient. The operators are sourced through a third-party agency, which is believed to have offered the people sent to express warehouse basic training on stock management, as the service level agreement. This has proved not to be the case – when the employees arrive at the dark store, they lack skills such as the ability to perform daily quality assurance checks, basic stock counting skills and the ability to use a digital scanner. As a result, the company receives orders for out-of-stock items, and products that are not of a good quality and that have packaging defects are picked.
- Owing to outsourced marketing resources, most of the dark stores are not living up to their potential because people are unaware of the availability of the service in their area.
- There are no standard operating procedures. The operators are supposedly trained by the agency they come from. However, upon their arrival at the dark stores, they are not familiar with the process to be followed, making it difficult to identify gaps in the process.
- There is a lack of live visibility of the operation; the ERP system only updates after 12 to 24 hours.

4. DISCUSSION

The findings of the study clearly indicate that there is a large market for e-commerce in the country in that the numbers presented show that customers do, indeed, buy from online grocery retail outlets. The most important aspect of the study is that it identifies gaps in the processes of the organisation that was studied. The organisation needs to implement measures to optimise its operations to be able to meet customers' expectations. The company's status as a start-up in South Africa might be a contributing factor to its current non-value-adding activities or inefficiencies, given that it is still in a phase of self-discovery and the solidification of its position in the country and on the African continent.

The company does not have SOPs, making it very difficult to identify opportunities for improvement or to determine who needs what training to be able to reach a desirable level of performance. This is why issues related to platform integrity are the leading causes of complaints received by the company. Employees do not have a standard to follow and merely perform tasks as per their contracts or offer letters.

From the literature review it is evident that the topic under investigation is fairly new to the South African market since there are gaps in the extant literature. This is something that became more popular during the COVID-19 pandemic, that is, from late 2019 to early 2022. The government restrictions forced citizens to use online modes of shopping.

The findings of the study will give South African online grocery retailers a better understanding of their customers' online grocery needs and service quality expectations. Based on the findings, online grocery shopping is still in an early stage of becoming a profitable business model.

Many factors were identified as contributing to a low level of confidence in online grocery shopping. Among these factors is order picking, in that consumers are still not confident that pickers will select the correct quality of perishable goods. Moreover, the return of goods may be an inconvenience for consumers, and consumers are not always able to receive their orders in person OR consumers are not always present to accept the delivery of their orders?. All these factors present an opportunity for retailers to capitalise on potential market opportunities that can help build consumer confidence while increasing their market share.

Consumers have high expectations regarding the level of service they receive based on their willingness to pay for delivery services. Meeting high service level expectations at a low cost poses a significant challenge for service retailers. Retailers should consider offering free delivery for orders exceeding a certain value as a way of increasing online orders.

this study provides valuable information for any retail company looking to increase its market share through a better understanding of consumer needs and expectations regarding online grocery shopping. These findings can help guide the development of grocery retailers' business strategies. The findings of this study also add to the limited information that the country has on the e-commerce industry, particularly the food and grocery sector.

5. RECOMMENDATIONS

5.1. Developing Standard Operating Procedures

A standard operating procedure is a set of written instructions that describes the step-by-step process that must be followed to perform a routine activity correctly. To ensure that an organisation remains consistent and in compliance with industry regulations and business standards, SOPs should be followed the same way every time. This will eliminate or reduce the level of complaints received, in that all departments will know what is required of them. From the platform integrity team to the delivery team, all the elements of the process will be noted. Every team member should sign an acknowledgement of the SOPs to show that they understand what is required of them.

This approach offers the following advantages:

- There could be a reduction in the number of complaints resulting from a lack of quality assurance because everyone will know how to perform quality assurance checks.
- There could be a reduction in instances where the wrong items are packed into customers' orders because the platform integrity team will have an SOP that gives step-by-step instructions on how to add an SKU to the app.
- Reporting on metrics could be improved, in which case it would no longer be necessary to wait 24 hours for management to refresh the app to see performance.
- The team will know how to conduct weekly cycle counts and daily stocktakes to ensure that the physical stock matches the customer app to prevent orders for out-of-stock items.
- Training provided to the store operators will help to create an efficient operation.

The use of SOPs has two major advantages: consistency and a reduction in the number of errors made. SOPs can also assist an organisation in evaluating employee performance, saving time and money and creating a safer workplace. Furthermore, SOPs can help to improve communication throughout an organisation. If a task changes, the relevant SOP is updated and redistributed to everyone who uses it, allowing the organisation to communicate the change to everyone who is affected in an efficient manner. SOPs also reduce the possibility of misunderstanding because the detailed steps leave little room for debate or questioning.

The implementation of SOPs may help an organisation by

- improving the efficiency of the operation
- helping improve management of the operation and employee training activities
- helping ensure the organisation produces reliable results
- aiding in the identification of areas for improvement
- improving internal communication
- helping with the implementation of a stock-on-hand reporting system

5.2. Developing Business Management Policies

It is general knowledge that customers manipulate systems once they figure them out. It is therefore very important to develop business management policies that clearly outline the procedures for a returned item, an exchange, a refund and the crediting of a customer's account.

5.3. Review the supply chain process

Steps for reviewing the supply chain process of online grocery retailers such as the organisation that was included in the study are as follows:

- On the basis of identified challenges, problems and bottlenecks, review the supply chain process on a high level to come up with a process that is optimised and saves the organisation money. Review the last mile of delivery to be able to provide riders with a market-related income split as the organisation's external logistics providers.
- Review the order fulfilment process and identify areas for improvement.
- Improve the cold chain of the organisation. From the above findings it is evident that a leading cause of customer complaints is the quality of perishable products and frozen meat.
- Optimise the digital scanners and have them linked to the platform integrity app or system.
- Implement daily stock-on-hand reporting to be able to track out-of-stock goods and to establish reorder points from the demand trend.
- Keep a stock-on-hand report or an out-of-stock report that reflects the fast movers in a certain DC, the rate of sale of products and a formulated reorder point to be able to manage the amount of each SKU being sent to the warehouses.
- Implement a delivery schedule plan in relation to stock availability and product rate of sale.

5.4. Improve online platform integrity

Steps for improving the platform integrity of the website of an online grocery retailer such as the organisation that was included in the study are as follows:

5.4.1. Creating a multilingual site

Having a multilingual site would promote diversity and inclusion, given that South Africa is a multicultural nation. Most customers would prefer being spoken to in their mother tongue. A connection is made with customers when they are communicated with in their own language. When it comes to e-commerce, the likelihood of making sales is higher when customers are communicated with in their mother tongue. Translating a website into different languages would not require much work, and the potential advantages of doing so are immense. Since the present markets are already saturated, making a website multilingual would aid in an organisation's exploration of new markets.

5.4.2. Improving the quality of product photographs

A high-quality picture can speak a thousand words. The best way to grab people's attention is by using appealing images. Every online store should make an investment in dependable, premium images. Images reassure online buyers and help them find the products they are looking for. E-commerce companies should take advantage of the visual nature of the world.

5.4.3. Adding a live chat option for customer support

A poor customer care experience results in the loss of a customer. The presence of a live chat option helps to convert browsers into customers of an online store. Customers are more likely to make purchases from an online store that provides online chat and support options, according to research.

5.4.4. Making site navigation better for simpler product searches

The navigation and the layout of a website must be consistent. A website must be simple to navigate and straightforward for users. An online store could lose clients because they cannot find products on its website and leave the site thinking the store does not carry those products. How simple it is for a visitor to find a product on an online store's site depends on the layout of the main website and the flow of products. In the case of a multilingual website, it is preferable to develop a landing page where customers can select a preferred language. The wording and the vocabulary used on a website should be consistent.

5.4.5. Optimising the site for speed

An online store can improve customer experience by optimising the speed of its site.

5.4.6. Focus on food safety

Many retailers focus on promoting food safety since e-commerce is growing and accounts for a relatively high share of overall sales, especially in the light of the shifting fulfilment landscape. Retailers will be compelled to modify their fulfilment procedures in order to comply with the requirements for food safety.

5.4.7. Reduce Capital Expenditure

While automation and micro-fulfilment facilities have their uses, most merchants will continue to run their businesses by using their physical locations as e-commerce distribution centres. Operating models will be developed that assist merchants in lowering capital expenditures and scaling up swiftly to meet surges in consumer demand, without having to set aside a sizable amount of space for order staging. As far as space is concerned, it is common practice for merchants to convert underperforming sites into dark stores in order to enable online orders.

5.4.8. Increase payment options

Many South Africans will continue to grapple with unemployment and underemployment during the economic recovery. Online stores should increase the payment options they offer by introducing, for example, non-fungible tokens or cryptocurrency, thereby opening up online purchasing to a rapidly expanding market segment

5.5. The future of e-commerce in South Africa

The value of e-commerce operations in South Africa is expected to increase by 150%, to R225 billion, by 2025 because of a significant shift in consumer behaviour and expectations brought about by COVID-19 unprecedented events [15]. First National Bank (FNB) has seen average e-commerce spend grow by 30% year-on-year during the first half of 2020 compared to 2019, whereas physical spending declined by 12% year-on-year during the first half of 2020 compared to 2019. The above statistics clearly indicate the growth that the country has seen in the e-commerce sector. It is therefore of the utmost importance to continue educating online retailers about this emerging market and to find ways of competing in it successfully to contribute towards the economic growth of the country.

ABSTRACT

Queuing is a common insight in the banking industry. The high demand for the use of Automated Teller Machines (ATMs) has posed some significant problems which includes poor service facilities and delivery which remains an unavoidable cause to the long waiting queues, poor service patterns which in turn affects queue discipline, and poor service delivery at the shopping centres in South Africa. This study describes the application of queuing theory designed to support the decision-making process by the banks to meet the demand. The study demonstrate how well queuing models can be applied to analyse and understand the behaviour of the queues particular in the banking sector. Considering our findings, we are of the view that there is a significant need for efficient ATMs service facilities and awareness of the benefits of automated teller machines to improve the adoption of a cashless policy in South Africa.

Keywords: automated teller machine, queuing theory, process optimization, industrial engineering

1 INTRODUCTION AND BACKGROUND

The high demand for the utilisation of Automated Teller Machines (ATMs) in shopping centres has posed some significant challenges which comprises poor service facilities and delivery which remains an unavoidable cause to the wastage of customers' time, lengthy waiting queue discipline and poor service delivery which could result in poor service facilities affecting the overall bank performance. ATM machines can perform extra functions such as money transfer and cell phone recharge [1]. South Africans continue to use the most popular applications for bill payment, cash withdrawals and balance enquiries. Thus, the physical movement of currency is reduced, compared to regular bank visits [2]. The adoption of ATMs has brought major challenges to the banking industry in terms of risk exposure and long waiting times. Several studies have been carried out on the effect of ATMs on the performance of deposit money banks in South Africa with different conclusions and results [3]; [4]; [5]. These remain factors to the perception of consumers about the ATMs and their banking companies. The need to see how the ATMs can be more efficient and speedily servicing consumers has prompted this study to be conducted.

Queues are part of our daily lives and are one of the most inconvenient aspects of modern life. Queues are formed as a result of an increase in service demand. if a service facility is unable to fulfil the customer's service within a certain time frame, the client will require excessive time to receive service [6]. Customers often dislike having to wait for a service. Consumers frequently regard time-saving and convenience as two of the most essential reasons for acquiring a good service.

The world has witnessed an upsurge of ATMs instruments meant to facilitate trade and simplify payments [7]. Bank customers had to walk long distances to do transactions of all kinds. They had to queue up and spend hours to talk to a teller to make their transactions and inconveniences were caused by these long queues [8]. New information technology (IT) is turning into the most important factor in the future development of banking, influencing bank's business goals and marketing strategies. Information development comprises the data that a banking business makes and uses, similarly as a wider extent of more composed advances that communication of data offers [9]. Computerisation of consumers' accounts and information recuperation, store and withdrawal ATMs permit access to accounts from any Bank are generally examples of information advancement for Banks. The usage of ATMs makes financial transactions more convenient. As a result, it is not a surprise that the use of ATMs has grown in most South African shopping centres. The ability of a business to sustain and retain existing customers is more important than gaining new ones.

2 LITERATURE REVIEW

2.1 Concept of Queuing Theory

Queuing can be defined as a line of entities waiting to be assisted [5]. A queue occurs when a customer or an entity arrives faster than they can be served. Queuing theory can be described as the study of waiting lines. Queuing theory is one of the quantitative analysis techniques that is used to analyse queues [1;7]. Queuing theory is applied in situations where decisions need to be made to reduce waiting times with the least amount of investment [3]. Queuing models are used in a situation where a waiting line criterion is met. A waiting line criterion is met when a waiting line consists of the components of waiting line.

Queueing systems are simplified mathematical models to explain congestion. Broadly speaking, a queueing system occurs any time 'customers' demand 'service' from some facility; usually both the arrival of the customers and the service times are assumed to be random. There are four assumptions made when using the queuing model: 1) customers are infinite and patient, 2) customer arrivals follow an exponential distribution, 3) service rates follow an exponential distribution, and 4) the waiting line is handled on a first-come, first-serve basis

[11]. An ATM allows customers with credit or debit cards to carry out basic banking transactions without the aid of a human bank teller. Customers can use them to withdraw cash, and check their balance. Card readers, cash dispensers, PIN pads, receipt printers and monitors are some of the basic hardware components that go into all ATMs. Many ATMs also have components for wireless connectivity, check scanning, or even dispensing gift cards [11].

2.2 Multichannel Queuing Model -M/M/S MODEL

Queuing model is essential to decision making predominantly on how to manage queuing systems in the most effective and efficient manner. The queuing theory and the most-widely used model is the M/M/s model which is the single line, multi-server, single-phase model assuming there are 's' identical servers, the service time distribution for each server is exponential, and the mean service time is $1/^{\mu}$ [5];[10]. Further to this, Multichannel queuing systems mean when there is more than one counter to serve the same service to a different customer.

ATM Transaction Model:

The Queuing or waiting line is commonly labelled as M/M/c/K, where first M represents Markovian exponential distribution of inter-arrival times, second M represents Markovian exponential distribution of service times, a positive integer (c) represents the number of servers, and K is the specified number of customers in a queuing system [10].

M/M/1 queuing model:

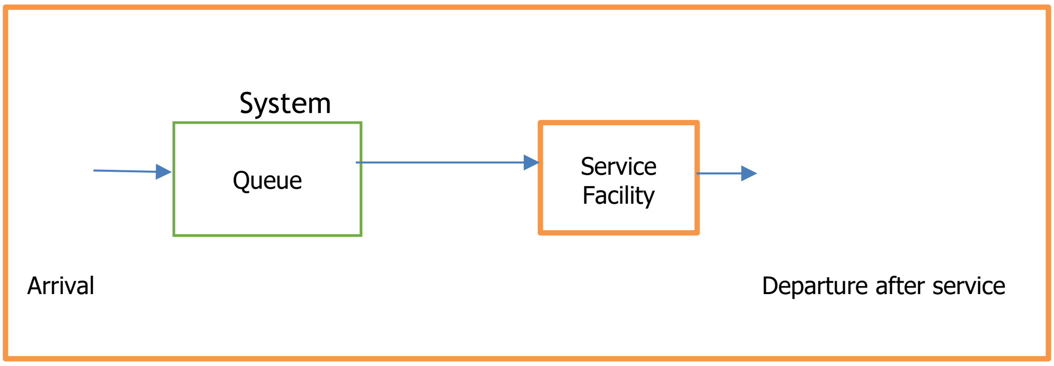

Figure 1: M/M/1 queuing model

M/M/1 queuing model means that the arrival and service time are exponentially distributed (Poisson process). For the analysis of the cash transaction counter M/M/1 queuing model, the following variables will be investigated:

λ: The mean customers arrival rate

μ: The mean service rate

$\rho = \frac{\lambda}{\mu}$: utilisation factor *(1)*

Probability of zero customers in the ATM: *(2)*

$P_0 = 1- \rho$

The probability of having customers in the ATM: *(3)*

$P_n = P_0 \rho^n$

The average number of customers in the ATM: *(4)*

$L_s = \frac{\rho}{\ } = \frac{\lambda}{\ }$

$1-\rho \qquad \mu-\lambda$

The average number of customers in the queue: *(5)*

$$L_q = L \times \rho = \frac{\rho^2}{1-\rho} = \frac{p\lambda}{\mu-\lambda}$$

W_q: The average waiting time in the queue: *(6)*

$$W_q = \frac{L_q}{\lambda} = \frac{\rho}{\mu-\lambda}$$

W_s: The average time spent in the ATM, including the waiting time *(7)*

$$W_s = \frac{L}{\lambda} = \frac{1}{\mu-\lambda}$$

Now, the study discusses the same for M/M/s Model

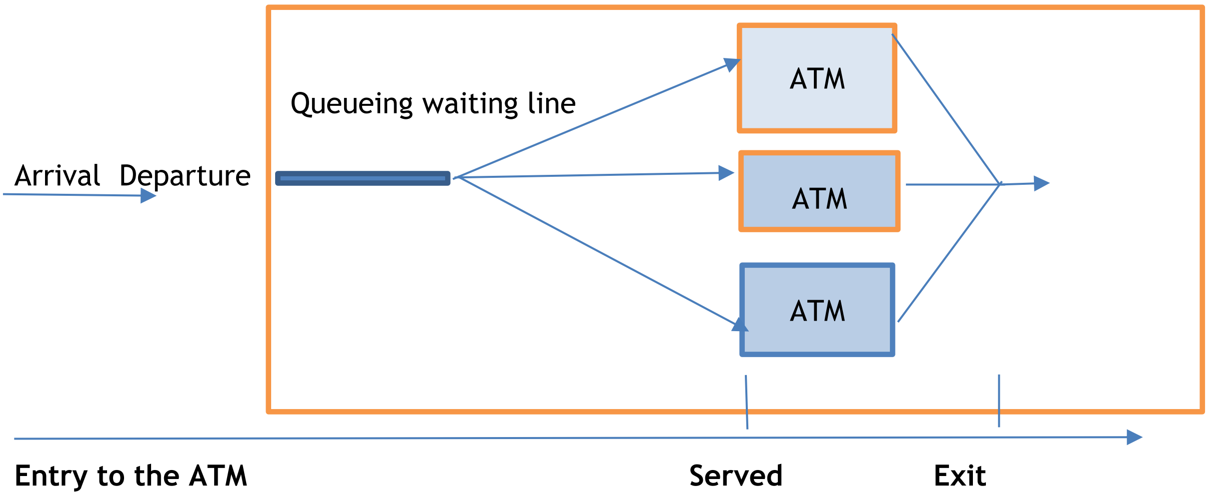

Figure 2: Single-Line, multi-server, single-phase model

The assumption that determines the parameters of the queuing model depicted in Figure 2 is subject to the following:

a) The customers' arrivals at the ATMs are random rather than schedule;

b) The customers' arrival time is unlimited or infinite;

c) Customers are service in the order they arrive and apply a notion of first come first serve (FCFS);

d) Customers arrive independently of each other and follow the Poisson distribution model;

e) Service times can differ from customer A to customer B, and are independent of each other and to note that customer A may have different service needs and times).

3 RESEARCH METHODOLOGY

3.1 Research Approach

A quantitative research approach was adopted to collect data, and analyse and answer the research questions. Furthermore, literature was reviewed to ascertain the current knowledge and data available on the effect of automated teller machines in the South African shopping centre. Participants from ABC Bank ATMs shopping centre consumers were selected using purposive sampling. The adoption of quantitative data analysis helped to turn raw numbers into meaningful data through the application of critical and rational thinking [12]. According to Creswell [13], quantitative data analysis may include the calculation of frequencies of variables and differences between variables.

3.2 Data collection

Data for this study were collected from ABC Bank in South Africa. The methods used for data collection were personal interview and observation by the researchers. Data were collected for two weeks. The following assumptions were made for queuing system which is in accordance with the queue theory. They are:

a) Arrivals follow a Poisson probability distribution at an average rate of customers per unit of time.

b) The queue discipline is First-Come, First-Served (FCFS) basis by any of the servers. There is no priority classification for any arrival.

c) Service times are distributed exponentially, with an average of customers per unit of time.

d) There is no limit to the number of the queue (infinite).

e) The service providers are working at their full capacity.

f) The average arrival rate is greater than average service rate.

g) ATMs here represent cash transactors.

h) Service rate is independent of line length; service providers do not go faster because the line is longer.

A set of both open ended and closed end questions were developed prior to the interview with the bank's consultant [14]. The questions were:

- How many days in a week does the ATMs operating?
- What are the operating hours for the ATMs?
- On average how long does a customer take when using the ATM?
- Do you have ATM statistics (how many people use the ATMs for an hour/day)?

For this study, the optimum number of ATMs in the Bank, two opposing costs must be considered in making these decisions: (i) Waiting time costs of customers and service costs. Economic analysis of these costs assists the Bank management to make a trade-off between the decreased waiting time costs and the increased costs of providing better service of customers from providing that service.

Expected Service Cost E (SC) = SC_s

Where, S =number of ATMs, C_s =service cost of each ATM

Expected Waiting Costs in the queue E (WC) = $(\lambda W_s) C_w$

Where λ = number of arrivals, W_s = Average time an equal spends in the queue

C_w = opportunity cost of waiting by customers

Adding (1) and (2) the study has,

Expected Total Costs E (TC) = E (SC) + E (WC)

Expected Total Costs E(TC) = SCs + (λW_s)

Other instruments - A watch was used to record the time. A clipboard and pen will also be used to assist with the data collection.

3.3 Data Analysis

The appropriate research design for the study had to be the one that addressed the 'what' and 'how' exploratory questions as unambiguously as possible in order to understand the concept of automated teller machines, the application of queuing theory using simulation tool in the South African shopping centre [15].

3.3.1 Customer Arrival and service rate

The average customer arrival rate in the system was computed based on the observation data [16]. An arrival distribution was determined and graphically displayed. A Poisson distribution was used to model the arrival distribution. The service rate at this point is the time it takes a customer to use the ATM.

3.3.2 Simulation Modelling

The queue system was simulated on Arena software to determine: a) the average number of customers in the queue b) average time customer spends waiting c) probability of waiting d) system utilisation factor.

3.3.3 Forecasting tool

The forecasting tool is populated on Microsoft Excel, and it consists of the moving average, weighted moving average, exponential smoothing and regression methods [17]. The actual hourly arrival rate was captured into the different models to measure the model's accuracy [11]. The accuracy of the model was tested using the different measures of accuracy methods. The results for each forecasting method were illustrated using a table and graphs. The following measures of accuracy methods were be used:

- Mean absolute deviation (MAD)
- Mean Squared Error (MSE)
- Mean absolute percentage error (MAPE)

4 RESULTS AND DISCUSSION

The ABC Bank had two ATMs and the first ATM handled withdrawals. The second on handled both deposits and withdrawals. Service time distribution for depositors and withdrawers was μ = 4 minutes/customer. The arrival rate for the depositors was λ =15/hour. The observers or researchers have assumed the opportunity cost of waiting by customers as Rs.1.6 per minute or Rs. 1/hour, as depicted in Table 1.

Table 1: Service time distribution for depositors and withdrawers

Performance Measures	For withdrawers (per hour	For depositors (per hour)
Arrival rate (λ)	16 customers	20 customers
Service rate (μ)	22 customers	22 customers
E (Service Cost)	Rs. 600	Rs. 600

Performance Measures	For withdrawers (per hour	For depositors (per hour)
E (Waiting Cost)	Rs. 250	Rs. 390
E (Total Cost)	Rs. 850	Rs.990
E (Grand Total)	Rs.1840	

If both the ATMs handle withdrawals as well as deposits, the following results are obtained using M/M/s model:

Table 2: Performance measures

Performance Measures	s=2
Arrival rate (λ)	36 customers
Service area (μ)	44 customers
E (Service Cost)	Rs. 1200
E (Waiting Cost)	Rs. 575
E (Total Cost)	Rs. 1775

The results show that optimal server level is achieved when both the ATMs handle deposits as well as withdrawals with a minimum total cost of Rs. 1775 per hour against the present total cost of R1840 per hour, as depicted in Table 2.

4.1 Verification and Validation of the Model

By definition, verification is the process of making sure the model operates as anticipated, based on the assumptions made during the modelling process. It is iteratively checking that the results of each stage in the construction of the simulation model meet all the criteria set forth by the preceding stage. Validation is making sure the model acts exactly like the real system. Validation entails ensuring the simulation model is developed in a way that represents the real system [1]; [7].

4.2 Verification and Validation Techniques

Historic data was used to validate the simulation model. The simulation results were compared with the collected historic data. Single entities were allowed to enter the model and proceed to go through the system. The results were monitored to ensure that the model data and logic is consistent and correct [5].

5 CONCLUSIONS AND RECOMMENDATIONS

The queuing characteristics at the ABC bank were analysed a Multi-server queuing Model and the waiting and service costs were determined with a view to determining the optimal service level. The results of the analysis indicated that the average queue length, waiting time of customers comprising the total cost could be reduced when the customers make deposits and withdrawals at the ABC bank ATMs. Th bank managers can recognise the trade-off that must be considered when dealing with the cost of customers waiting time and the cost of providing better service. Service cost rises as a business tries to increase its level of service, and the cost of time spent waiting on the line reduces. Thus, adding more ATMs in the same shopping centre could help optimise the operations of the ABC bank. Exploring on improving operational efficiencies and service quality through process improvements. Monitor/quantify the customers who leave the queue due to the length and waiting time. Hence, further studies can be conducted focusing on all ATMs from various banks in the same shopping centre, and the concept of online and mobile banking can be adopted in order to gather data will help to improve banking industry.

ABSTRACT

Due to the nature of the research problem, this study focused on the application of A3 Methodology to investigate the root-cause to poor performance at an E-coating plant. Preliminary observations showed that there were too many complaints from the production management team regarding the poor performance of the production line. The selection of this method allowed the researcher to collect numerical data to examine the application of the methodology. Qualitative data was used to collect and analyse data in terms of the favourability of the approach. The investigation showed that the A3 methodology can be used as a methodology to improve processes in the production environment. The results of this study ratified that the e-coating plant is performing below the target due to process variations in the production line and constant monitoring of the production area is required to highlight problematic issues.

Keywords: industrial engineering, A3 methodology, process optimisation

1 INTRODUCTION

The organization is a 3rd generation family business that has been providing competitive manufacturing solutions to major OEMs and Tier 1 suppliers in the South African automotive industry and export markets for approximately 50 years. The manufacturing facilities in Pietermaritzburg, KwaZulu-Natal, and Rosslyn, Gauteng, South Africa, produce a wide range of components using a variety of manufacturing technologies. Supplying some of the world's leading automotive companies requires world-class standards and a focus on continued competitiveness is driven daily.

In addition to metal stamping and welding, the organization encompasses a variety of manufacturing technologies to meet the needs of customers and products. Within the departments, the company offers polymer injection molding, metalworking, forging, tube bending, synthetic leather stitching, and various surface treatment processes (galvanizing, e-coating, powder coating, wet spray painting), as well as many highly automated assembly processes.

The pre-treatment process involves 13 tanks for cleaning the material and takes 38min. Pre-treatment is the first step of the process. This is where metal is cleaned and a phosphate is applied to prepare the surface for application of the e-coat. This process is significant to attaining the performance requirements anticipated by product customers. Electro coating applications use paint particles suspended in a fluid bath [1]. The process occurs as the metal part is dipped into the bath or paint tanks which allow these paint particles to mix and build up on the entire surface of that part which will form an even continuous, low-profile film.

2 LITERATURE REVIEW

2.1 Time studies and Capacity planning

Many companies still prioritize the application of work study when solving capacity planning problems. Work study is a universally accepted technique that includes method studies and work measurement to improve production effectiveness or productivity of the organisation by completely highlighting waste and unnecessary operations [2]. This technique is useful to identify non-value adding operations by looking at all the factors affecting the specific work performed [3].

2.2 Kanban boards:

The Kanban is a continuous improvement technique of materials handling in production that ensures a strong interrelationship between the assembly line or production line and the production support departments. The work Kanban is a Japanese version for visual record or visible documentation in English.

The Kanban which are represented as the production orders are collected in a box and it is called Kanban board. The board is completed comprise of a number of columns for each product and then separated into 3 different zones [4;5].

• There’s a Green Zone: This represents the highest production cost also means ahead of production. It has a low attention for following up to it which means it is a safe zone.

• There’s a White Zone (or Yellow): This represents production is normal. It receives the same attention as the green area, however it is a warning signal, and it cautions that are slowly about to be falling into the red zone arms.

• There’s a Red Zone: This zone represents an emergency and signals crucial production. This will immediately give an alert that there is a stock out for that specific product and means that instant container refill is required when the machine is available.

2.3 Gemba Walks

A Gemba Walk is a technique mostly used by a management team whereby they take a walk in the production line with the aim of observing and understanding how work either from the operators or the production supporting system is being performed [5]. Gemba is another word which is drawn from the Japanese word that is Gembutsu, and its English version means a real thing or real place [6].

A Gemba Walk has different elements to its function and the elements are:

Observation – This is watching the production team perform their tasks in-person.

Location – This is observing the production team at the actual location where their duties are performed.

Teaming – This is interacting with the production team performing the work.

The Gemba Walks approach offers an up-close, complete view of behaviours in action and also considered as useful tools for pinpointing process improvement opportunities and new possible ways to support the responsive team. This proves to be an effective method for the company's management to see how their active teams are demonstrating agile values [7].

2.4 A3 Methodology Evaluation

One of the most important ways to gather the necessary information to provide an effective solution is the A3 methodology. The A3 methodology was developed by Toyota in the early 1960s as a technique for problem solving and continuous improvement. In order to gather the necessary information and provide effective problem solutions, one of the main practices for identifying and solving problems is the A3 methodology, which originated from the systematic production of Toyota Motor Corporation [8].

In recent times, the pressure on the manufacturing industry to seek to run operations more efficiently has increased rapidly. Organizations realize that in order to help their organization achieve its goals or objectives, they need to improve their entire workforce [9].

The A3 report begins by identifying the problem, determining the current state of the process, determining the cause of the problem, determining how to solve the problem, evaluating improvements and determining the effectiveness of the process. The application of the A3 problem-solving process demonstrates the applicability and payoff of the approach in manufacturing [10].

Process reorganization and improvements have also increased the efficiency of assembly line balancing. The A3 technique was standardized so that it could be used for future improvement projects since it played an important part in the project and allowed for the monitoring of the efficacy of the various improvement activities undertaken [10]. In their never-ending quest for continuous development, Toyota has spent many years developing and perfecting this skill [11].

3 RESEARCH METHODOLOGY

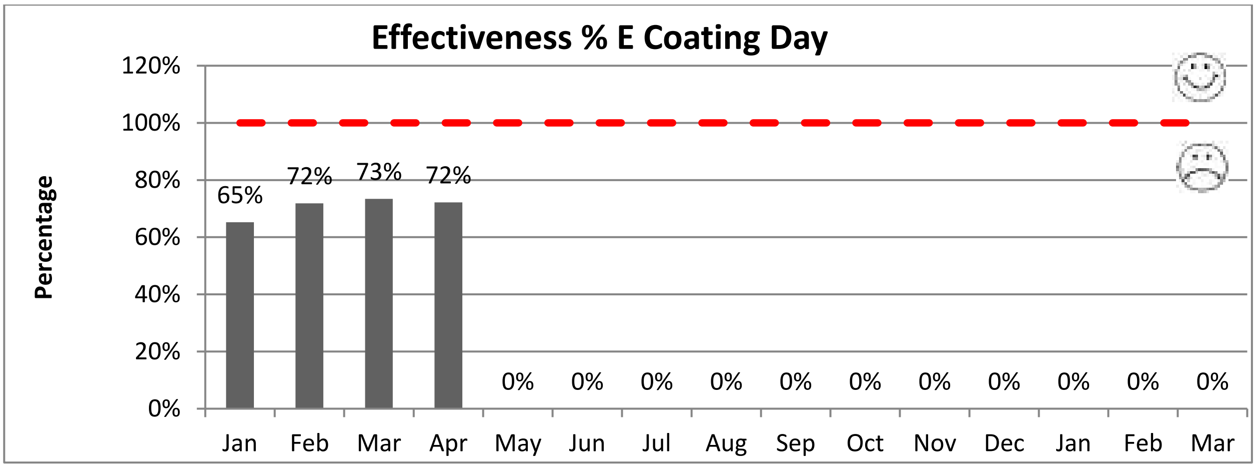
This research was conducted at an E-coating plant in Pietermaritzburg and the approach was based on a qualitative approach using case study analysis as a primary means of data collection. Direct observation using work-study principles were used to gather information from the production environment. Current data was collected through the recordings from production system. There's a total of 35 operators for the line, 4 for the Offline cleaning process (2 dayshift and 2 nightshift), 17 for the powder coating process (9 dayshift and 8 nightshift) and last is the 14 for the e-coating process (7 dayshift and 7 nightshift). The study is mainly focused on the 14 operators which would rotate weekly according to their production shift schedules.

4 DISCUSSION AND FINDINGS

4.1 Dayshift data collection and analysis

This primary data of the ethnographic study was captured using the production data collecting sheet was taken from the historical data of January, February, March and April which is the. The table below depicts the monthly trend of the E-coating production performance which shows that on average the dayshift does not reach the production target by at least **29%** compared to the **100%** target performance.

Table 1: Monthly E-coating production performance (Effectiveness %): Day - Shift



Following from the above effectiveness table is the Downtime percentages of the dayshift team which shows that on average the monthly percentage trend is **25%** with the highest downtime under Process with **18%.**

Table 2: Monthly E-coating production performance (Downtime %): Day - Shift

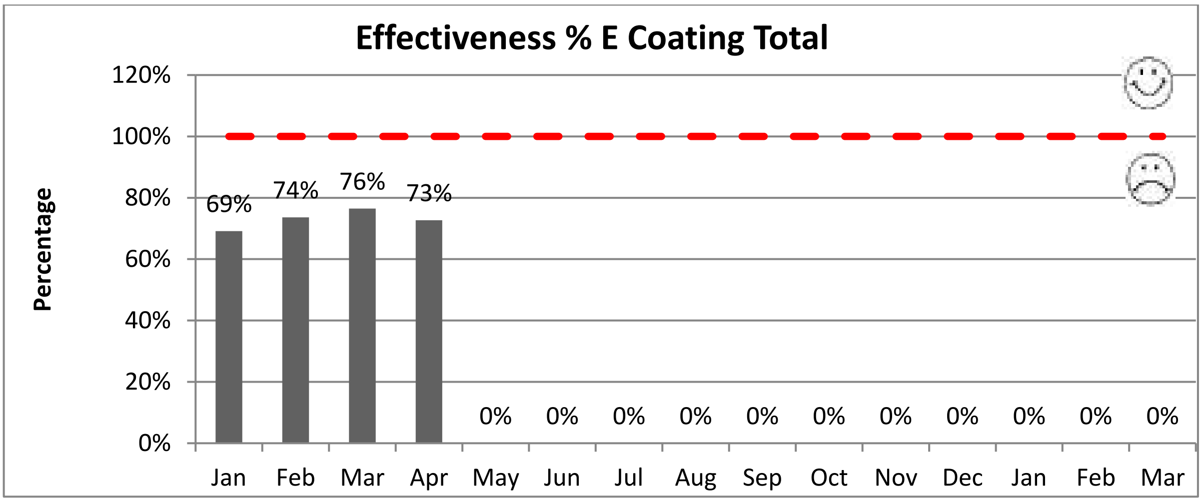
4.3 Dayshift and Nightshift data collection and analysis

When rating the total performance of the department, both dayshift and nightshift data is combined which is what gave a true reflection of the E-coating production performance. Normally the individual shifts data is separated for discussions during the shift's morning meetings whereby the shift-leader would be highlighting areas of improvements with the team in preparations to the Gemba Walks [12;13].

This is the continuous data from the individual shifts to show the combined results of the monthly trends for the 4 months. The results reflect that on average the department is at **27%** below from reaching the **100%** target performance.

Table 5: Monthly E-coating production performance (Effectiveness %): Day & Night - Shift



The below table reflecting the monthly trend for downtime percentage of the combined shifts, shows that on average the monthly percentage trend is **24%** with the highest downtime under Process with **16%.**

Table 6: Monthly E-coating production performance (Downtime %): Day & Night - Shift

Downtime % Effectiveness %

This is the weekly historical data of the e-coating production performance which reflect the background of the problem faced by the e-coating line. The graph shows that from a 100% target set, the line only achieved an effectiveness percentage of 83% and lowest downtime percentage of 19%.

This indicates that there are difficulties within the process that are affecting the production line to be fully utilized effectively. On analysis for possible root causes, the downtime percentages are then broken down to different categories to try and pinpoint the problem.

Table 8: Weekly downtime categories trend

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
C/O %	1%	1%	0%	1%	1%	1%	1%	1%	1%	0%	1%	1%	0%	1%	1%	1%	1%	1%
Reject %	1%	0%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%	1%
Material %	2%	2%	1%	1%	3%	6%	4%	1%	1%	0%	1%	1%	1%	1%	1%	2%	5%	2%
Process %	15%	16%	12%	15%	14%	16%	12%	17%	12%	12%	12%	14%	16%	14%	13%	22%	16%	14%

C/O % Reject % Material % Process % Machine % Man %

The table and graph highlights that E-coating production line has a high downtime percentage under the category of Process. The weekly data collected identifies the main problem occurs under the process which affects the utilization of the line.

4.4 Process Flow

The E-coating plant comprises of 4 different departments (Offline cleaning, E-coating, Powder coating and Assembly. All these departments operate in connection to each other with a common denominator which is the Offline cleaning. This is a pre-preparation process which most of the parts go through and it is effective because of zinc-phosphate chemical cleaning.

Below is the offline cleaning process tanks, manually operated using a crane in transportation of the Jigs from one tank to another:

Offline cleaning tanks

Table 9: Offline cleaning process

Time (in Sec)	Operation
240	Loading parts onto the JIG
25	Moving the JIG
240	Loading the JIG onto Tank 1(DEGREASER)
25	Moving the JIG
60	Loading the JIG onto Tank 2(RINSE)

Time (in Sec)	Operation
25	Moving the JIG
60	Loading the JIG onto Tank 3(RINSE)
25	Moving the JIG
480	Loading the JIG onto Tank 4/5(ACID)
25	Moving the JIG
60	Loading the JIG onto Tank 6(DRAG OUT)
25	Moving the JIG
60	Loading the JIG onto Tank 7(RINSE)
25	Moving the JIG
60	Loading the JIG onto Tank 8(RINSE)
60	Moving the JIG
60	Loading the JIG onto Tank 9(GRAIN REFINER)
25	Moving the JIG
180	Loading the JIG onto Tank 10(PHOSPHATE)
25	Moving the JIG
60	Loading the JIG onto Tank 11(RINSE)
25	Moving the JIG
60	Loading the JIG onto Tank 12(RINSE)
240	Loading the JIG onto Tank 13(NEUTRALIZER)
25	Moving the JIG to the Offloading bay
574	Offloading parts from the JIG

The process is designed that not all the parts pass through the offline cleaning when it is going to go through e-coating since the e-coating process begins with the cleaning tanks on its own.

Below is the process flow for Cover, Sub-Assembly Steering Column Hole RH & LH which is one of the components being manufactured.

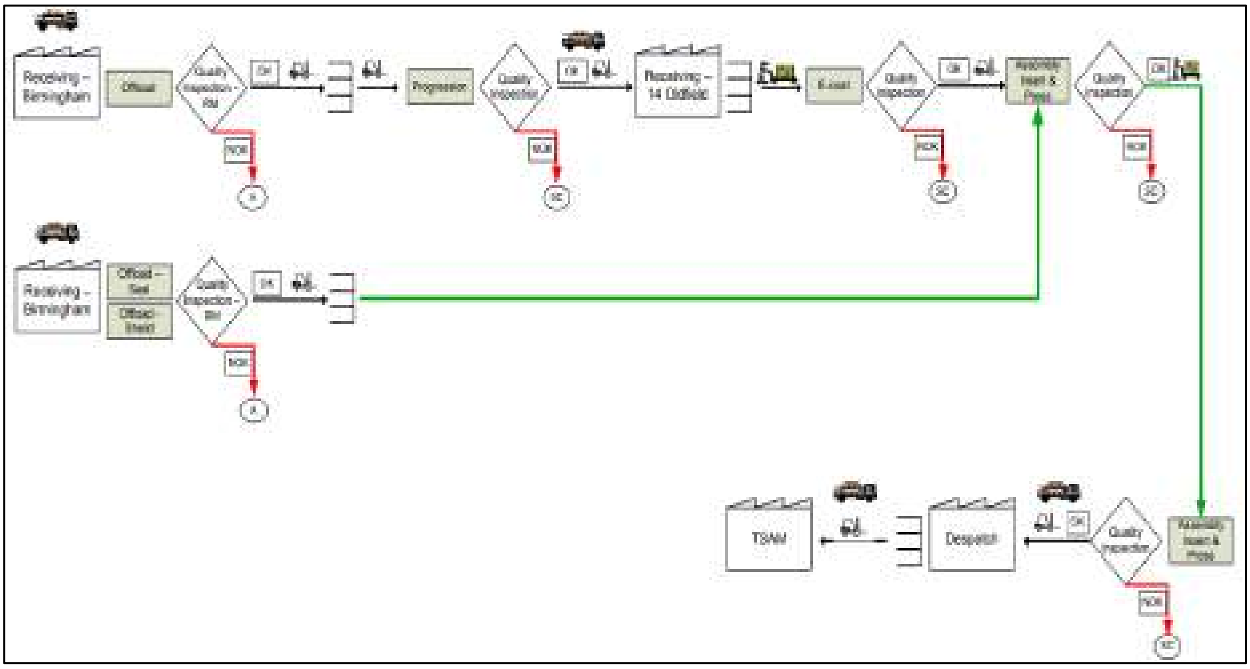

Figure 1: Process flow: Cover, Sub-Assembly Steering Column Hole RH & LH

The process flow displays the movement of the component from receiving until dispatch. This also shows all the quality inspection stages that the product is designed to pass through as per the process procedure. The main aim for the process flow is to show the area of focus for the problem and highlight the processes affected by the problem.

E-coating has 7 tanks for the process to complete:

- Tank 1 – Degreaser (Oil cleaning chemical tank)
- Tank 2 – Rinse tank (Cleaning degreaser to avoid chemical contamination)
- Tank 3 – Rinse tank (Cleaning degreaser to avoid chemical contamination)
- Tank 4 – D-ionized water
- Tank 5 – Primer Tank
- Tank 6 – Rinse tank (Preparing material for wet paint and removing excess primer)
- Tank 7 – Electronic coating

4.5 Investigation

The background scope of this study shows that the focus area is based on the process of the E-coating line. Under this process there's a number of difficulties faced as this is a chemical process which requires professional technicians.

Paint conformance: Testing of the paint is done only on Mondays at the end of the process. During the whole week all the parts run through the line based on the Monday's test results.

When the part's paint non-conformances to the specification than the whole batch is recycled on the conveyor but there are adjustments to the line as recycling only skips the other tanks and goes through tank 5, 6 and 7.

Falling of parts: During the e-coating process some parts may fall from the conveyor. If the components are small, the conveyor continues, however if it is large components fall then the line is stopped since it may damage the tanks.

Gaps on a conveyor: The conveyer speed is constant throughout the whole production time. The loading of parts is a manual process which requires that an operator ensures that all the hooks are loaded with the components.

This becomes a problem when there's a lot of components to load and the small items come in batches of 200 or more and thus to load the parts becomes difficult as the operator has to try and keep up with the speed.

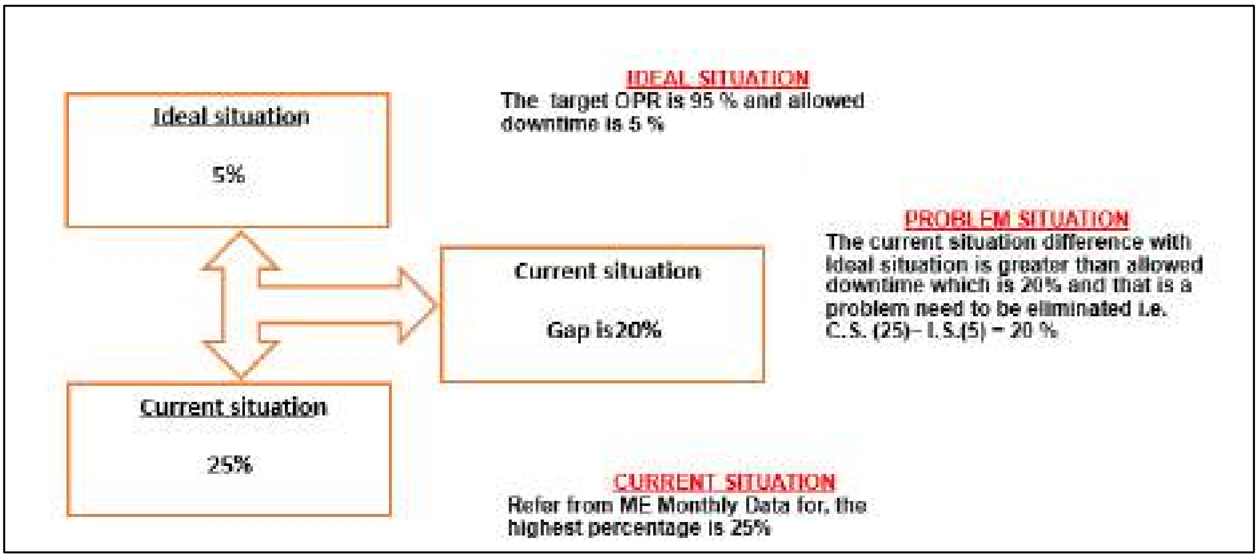

Figure 2: Current/Ideal situation

4.6 Root cause

Analysis of downtime

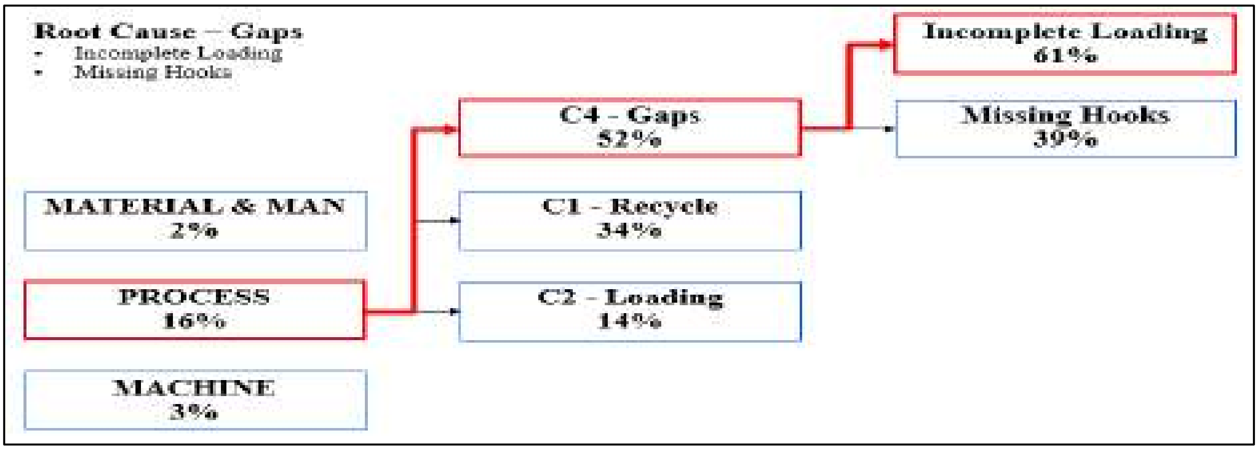

Figure 3: Identification of Gaps

4.7 Clarify the problem

In clarification of a problem, this step allows for an opportunity to analyse sub-problems and evaluate how to tackle each problem in order to find the solution.

1. Paint testing
2. Gaps on a conveyor
3. Parts falling of the conveyor
4. Product loading orientation

4.8 Investigation

The investigation phase involves interviewing production operators to solicit information regarding the sub-problems.

Table 10: Investigating sub-problems

Sub-problems	Investigation
Paint testing	Testing of the paint conformance at E-coating plant is one of the processes that require attention. This process occurs once a week during the weekly maintenance schedule. There is a two day lead-time for the results which are provided by a company located in Ballito. While the company waits for the results, the production can only hold-on to the parts until the tests are complete and approved.
Gaps on a conveyor	Investigation phase
Parts falling of the conveyor	Investigation phase
Product loading orientation	The loading procedure requires that each product has an identified hook for loading as per the standard operating procedure. Some of the large parts are loaded separately from the other small parts since they require human labour when loading. This means that they take a lot of space on the conveyor.

4.9 Set the target

In motivating for the study, the sub-problems aim for investigating possible solutions to the main problem as they highlight or prove to be possible root-causes.

Table 11: Set the target

SET THE TARGET	
1	Develop an efficient process for Paint Test.
2	Review the cycle times for the loading process to clearly identify the process capacity and purchase more hooks to keep as spare.
3	Review the quality of the hooks as they also require maintenance. Sanding off the paint is necessary since they are thickened during the process which enables the parts to sit flush and not fall off.
4	Continuous skill levelling is required to ensure that the standard is maintained. Reviewing of the loading orientation at least once a week and displaying of the standard on the notice board is necessary.

5 RECOMMENDATION AND CONCLUSION

The data collected provides an indication of the challenges experienced in the e-coating plant. This leads to low operator and machines performance. The data also shows the possible root-cause in the process of the production line for further investigation.

The methods used to approach this study were effective on terms of the application of industrial engineering principles. It is recommended that investments be made on the continuous development of operatives to enable them to function effectively in such an environment. Health and safety, ergonomics, protective clothing would assist operators in understanding their environment while meeting governmental policies. Constant monitoring of the production area in imperative to manage challenges that arise on a regular basis. Material handling and layout of materials are important for easy flow of work. Effective management, together with a trained team, will enable the continuous improvement of the E-coating plant with regular monitoring on the production environment.

ABSTRACT

Aviation in South Africa is experiencing numerous challenges, especially in the area of maintenance planning. Maintenance turnaround time at an aviation organisation increased by 40% between 2019 and 2021, which influenced the organisation's entire supply chain. The application of industrial engineering principles in the form of lean techniques was found to be the most suitable tool in this instance since it is a tried and tested technique. The objective of the study was to investigate aircraft maintenance procedures to promote process optimisation. Lean methods assist in optimising quality and delivering performance while reducing maintenance turnaround time. A qualitative methodology in the form of a case study was used for purposes of the study. The recommendations made based on the results and the findings of the study were welcomed by the organisation's management team for implementation.

Keywords: lean thinking, aircraft maintenance, industrial engineering, process optimisation

1. INTRODUCTION AND BACKGROUND

South African Airways Technical (SAAT) is a maintenance, repair and overhaul organisation (MRO) that services both local and international customers. SAAT's acquisition of a new Airbus fleet implied that the organisation added a full Airbus maintenance capability to its existing capability on the Boeing fleet. Aircraft maintenance entails arranging planned maintenance, choosing which aircraft registration to bring in at what time and determining which maintenance tasks to complete. Even for a relatively modest airline on a global scale, scheduling planned aircraft maintenance cost-effectively is a challenging task. It is estimated that aircraft maintenance organisations (AMOs) handle 54% of global airframe heavy repair, 78% of engine maintenance and 16% of line maintenance [1]. The most important objective is to pick up higher line performance, higher efficiency and, in the long run, a lower cost price, while keeping up the quality of the maintenance that is performed.

An aircraft manufacturer specifies in a maintenance planning document (MPD) how frequently various components of an aircraft need to be maintained. Compliance with MPDs is overseen by government officials. There is no doubt that maintenance planning will keep on changing because of the worldwide shift towards new automation systems and the fourth industrial revolution (4IR). These changes will affect the way in which people, technology and machines interact in the aviation industry to improve production. AMOs have highlighted the adoption of lean concepts from the management level to the shop floor in a determined effort to remain competitive in a changing marketplace in response to growing competition in places such as Europe [2]. Certain work processes in SAAT's production department have been identified as being redundant since they consume unnecessary time and effort and increase the cost of the organisation's product. Furthermore, these processes cause worker fatigue, which has hampered growth in productivity.

Heavy maintenance is carried out on an aircraft every 24 months. Heavy maintenance is described as the performance of maintenance tasks covered by C and D checks that involve accessing panels and access doors, as well as disassembly for a more thorough inspection and eventual repair. Heavy maintenance coincides with lengthy downtime periods and large maintenance packages measured in man-hours. An enhanced method is required for analysing aircraft usage requirements on a yearly, monthly and daily basis. In such a method, maintenance item intervals are combined with simulated aircraft utilisation situations (high, average and low usage) and maintenance scenarios in the system. From there, the maintenance demand can be determined (in terms of numerous trips and maintenance man-hours). Thanks to computers and other technological equipment, employees can accomplish most jobs automatically rather than manually [3].

2. LITERATURE REVIEW

Lean management is the process of helping a business to develop the quality of its product or service, its productivity and its efficiency. The adoption of lean methods has been cited by businesses as having a major positive impact on productivity and effectiveness across their individual companies. Many organisations that provide aircraft maintenance have also acknowledged the importance of implementing lean methods to improve their ability to compete in the industry [4]. The keys to maintenance scheduling are what to maintain, when to maintain it and how to maintain it. A system was developed for operators, manufacturers and regulatory bodies to share their experience and knowledge of these issues in relation to new aircraft being developed [5]. Flight service disruption occurs as a result of unplanned maintenance downtime, resulting in a loss of customer satisfaction regarding on-time performance [6]. Planning for aircraft inspections, or when an aircraft should be stopped and what inspection must be completed during its upcoming inspection, is a key component of optimising aircraft maintenance.

Lean tools and methods were first used in the Toyota Production System in Japan. Lean successes should be clear, particularly within a global aircraft maintenance organisation. A case can be made for lean management in the South African AMO industry in the light of the industry-specific evidence of its effectiveness, specifically the reduction in turnaround time (TAT) that results from the implementation of lean methods. While the financial benefits of lean methods may not be immediately apparent to an AMO, the customer benefits from the shorter lead times, giving the AMO a competitive advantage to keep and grow its business [7]. It is also much simpler to identify and address quality-related issues quickly through lean management [8]. Lean methods must be applied to aircraft maintenance, which necessitates implementing ongoing changes and streamlining the maintenance procedure [9]. Lean thinking offers systematic methods for identifying and eliminating waste through a pull strategy, enabling an organisation to stay competitive in the global market [10]. Manufacturers of aerospace products looked to the automotive sector for inspiration and started learning about the principles of lean manufacturing [11].

Using the five lean principles of value, value streaming, flow, pull and perfection as the framework for an organisation to understand the strategic approach of lean transformation, Womack and Jones [12] provide instructions on how to set up rules and deal with the difficulties that arise when a non-lean industrial organisation tries to transform itself into a lean organisation. Value-adding activities (VAAs) transform material and/or information in the interest of meeting the client's needs, whereas non-value-adding activities (NVAAs) are linked to the consumption of time, resources or space that does not add value to the product and/or the service that must be delivered to the client [9]. Lean tools and principles must be adapted to an MRO. The objective is to raise the organisation's performance on operational metrics by encouraging staff to look for ways to cut costs, which helps it stand out from its competition [9]. Prior to implementing lean thinking, the organisation should assess its readiness for the integration of lean methods into its current processes [13].

Two fundamental components of lean thinking are creating value and understanding value from the viewpoint of the ultimate customer [14]. Value can only be determined by the final consumer, and it only makes sense when it is expressed in terms of a particular product [7]. Lean manufacturing is the process of removing waste from all aspects of production, including supplier networks, production flows, maintenance, engineering, quality assurance and factory management. Value Stream Mapping (VSM) is a comprehensive tool that produces an overall picture of a production process, including both value-adding and non-value-adding activities. It provides a visual representation of every action, task or activity involved in a process and records the progression of every action, task or activity from beginning to end. In order to apply the appropriate lean techniques where they are needed to secure a greater and more lasting impact, mapping can be used as an aid in understanding the resources that create waste within the value stream. Instead of focusing on isolated process improvements, mapping makes it possible to see improvements in the entire process. The mass production method known as batch and queue involves producing a part in large quantities and then sending the batch to wait in line before the next step in the production process commences [7]. A product must flow from conception to launch, from order to delivery and from raw materials to delivery into the hands of the customer without any stoppage, scrap or backflow. This is accomplished by completing tasks in a progressive manner along the value chain [12]. Time reduction needs to be continuously monitored because improvement signifies improved process flow. Takt time is a crucial tool for implementing flow because it precisely synchronises the rate of production with the rate of customer demand [7]. A Japanese tool for cleaning and organising a workshop is the 5S system. In this system, visual controls are used to organise the workplace and to improve safety and efficiency while eliminating waste. Work in progress (WIP) can be managed using a pull system. Raw materials or WIP is only released by a pull system after the current WIP has been finished by the previous process steps. An example of such a system is the kanban inventory replenishment system that was invented by

Toyota. For inventory of raw materials or WIP to be moved forward into the following stages, the system generates a visual demand signal. Tasks and operations related to aircraft maintenance enable the forecasting of AMO demands. According to a maintenance schedule approved by the Civil Aviation Authority (CAA), an AMO schedules maintenance tasks based on the operating hours, the landings and the time in service of aircraft. A flight schedule, which changes depending on anticipated customer demand, is a requirement for aircraft operations. It has been necessary to see the value stream, the flow of value, and the value being pulled by customer at every lean principle. A company must set goals and share them with everyone to achieve perfection. The goal of a kaizen workshop is to eliminate waste through the identification and implementation of significant process improvements. There are other methods besides lean methods that AMOs can use to increase their productivity. To increase productivity in AMOs, lean methods are often combined with Six Sigma. Six Sigma is based on a strict and structured investigation methodology and emphasises the reduction of variation while being problem focused.

3. RESEARCH METHODOLOGY

The research questions were designed to generate words rather than numbers, a qualitative approach was adopted for the study. A qualitative research design is appropriate for gathering opinions on a particular subject or when studying human and machine behaviour. Data were gathered through a secondary systematic review, which involved searching for articles on the internet [15]. To achieve the goals of the study, exploratory research was used in this study to define the topic's breadth and scope.

3.1. Data collection

The researcher chose to use the method of questionnaires to collect data. Questions were asked on the education level and years of experience of the candidates. Knowledge on lean terminology and methods were in the questionnaire. Data was collected on the impact of lean in the aircraft industry and the questionnaire was designed accordingly. The following questions were addressed:

a) Department and years of experience in the company.
b) Number of participants per department.
c) Education level of participants.
d) Participants knowledge of lean terminology.
e) Status of the implementation of lean tools.
f) Effectiveness of lean methods in each department.
g) Opportunities and challenges of implementing lean methods/tools.

Furthermore, the researcher chose to observe the current system in use at the organisation. The targeted population consisted of selected maintenance technicians, maintenance planners, engineering analysts, scheduling analysts, production planners and quality assurers at SAAT because they are direct stakeholders in maintenance planning and scheduling. Four different methods were used to gather data: interviews, observations, documentation and archival records. During this study, the observer/researcher analysed data from a C check that was done on a Boeing B737-800 work package, which contained tasks completed on an aircraft, man-hours, material used and duration.

3.2. Data analysis

Thematic content analysis was chosen as the method of analysis for this study. Thematic analysis is a structured, inductive method for extracting and analysing themes from textual information in a transparent and reliable manner[16]. Tables, graphs, percentages and frequency distribution tables were used to demonstrate findings.

4. RESULTS AND DISCUSSION

A total of 68 employees contributed to the research study from an initial number of 74 participants who were chosen to participate in it. The response rate was 92%. The remaining 8% of employees did not complete the questionnaire because they were on leave. Management was willing to let the employees participate in the survey because they believe that using lean methods can improve productivity and profit while reducing costs. The chart below indicates the respective departments to which the participants were attached and the years of experience of the participants.

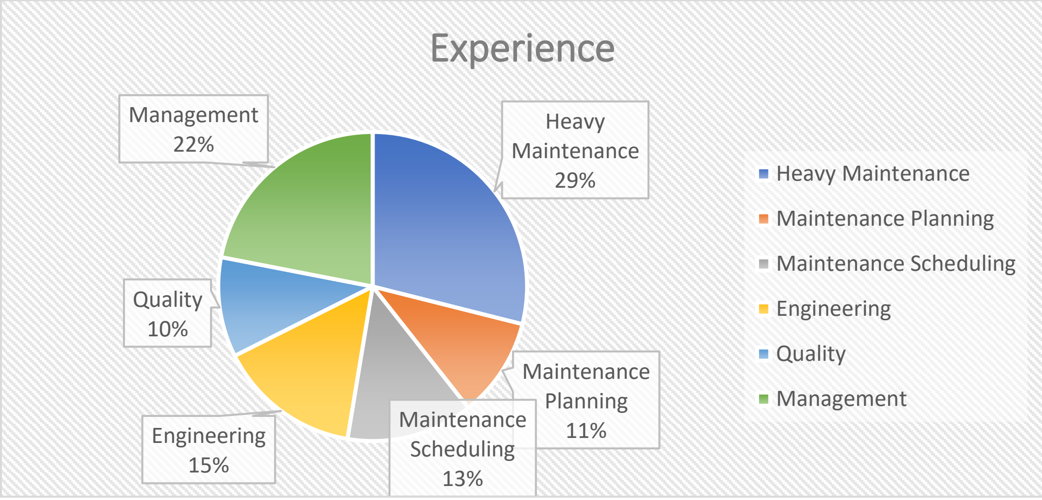

Figure 1: Participants: departments and years of experience

The total number of participants in this research was 68 of whom.

- 63% were artisans with experience of between 1 and 25 years.
- 8.5% were planners with experience of between 5 and 10 years.
- 7.5% were schedulers with experience of between 8 and 12 years.
- 7% were engineers with experience of between 5 and 15 years.
- 10% were quality controllers with experience of between 4 and 10 years.
- 4% were managers with experience of between 10 and 20 years.

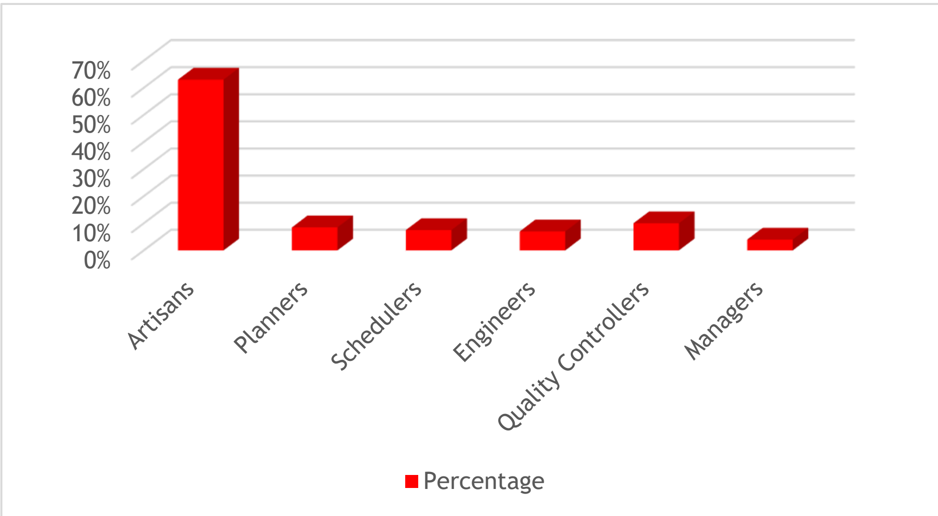

Figure 2: Participants per department

Based on the above overview of the participants, the researcher concluded that the experience that one has in the industry does not have an impact on one's contribution towards finding ways of improving aircraft availability by integrating planning and scheduling using lean methods. The participants involved in heavy maintenance were key people because they were faced with day-to-day challenges related to processes that were flawed because of the poor planning and scheduling of tasks. The chart below depicts the level of education of the participants.

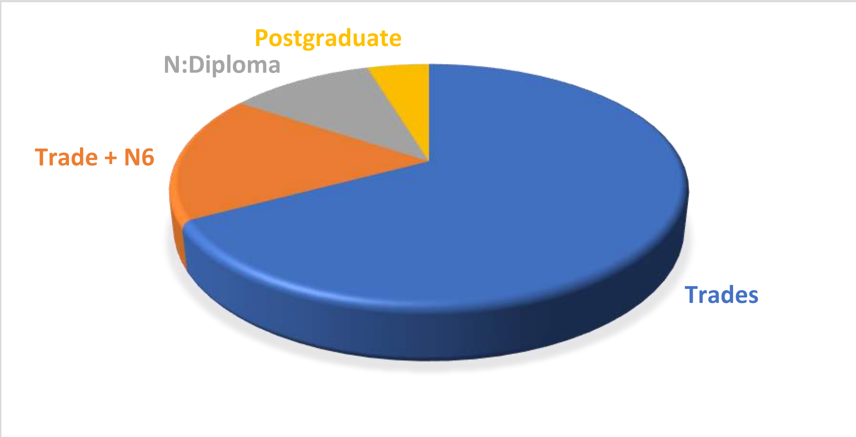

Figure 3: Participants' educational level

A total of 4% of the participants had a postgraduate qualification, 7% had degrees, 10% had N diplomas, 16% had trade certificates plus N6 and 63% had trade certificates only. Considering that the aviation industry requires knowledge of lean manufacturing and qualifications to integrate planning and scheduling using lean methods, the results paint a worrisome picture of the status of skills development in the industry. The proposed integration of planning and scheduling using lean methods requires certain knowledge of value streaming and kaizen. Employees of aviation companies require training and skills development to keep up with the global aviation industry.

4.1. Knowledge of lean terminology

A set of questions on lean methods was drawn up and used to test the participants' knowledge of lean methods.

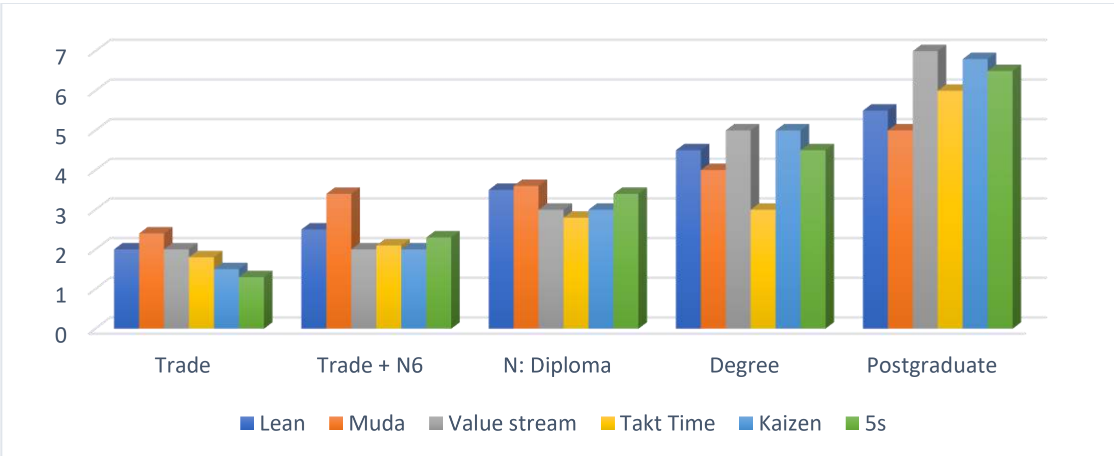

Figure 4: Participants' knowledge of lean terminology

The above figure shows that artisans who worked in heavy maintenance and whose highest qualifications were trade certificates had little knowledge of lean terminology. Likewise, participants involved in maintenance planning and scheduling had little knowledge of lean terminology. The company could invest in skills development to improve their skills, thereby bringing them on par with employees who have university qualifications and knowledge of lean manufacturing for the seamless integration of lean methods.

4.2. Status of the implementation of lean methods

The figure below indicates the status and experience participants encountered during lean implementation. Between 23% and 29% of engineering and quality departments, participants had a better understanding of lean methods implemented. The remaining departments ranged between 14% and 17%, which clearly shows that the participants had a moderate experience when lean methods were implemented in their perspective departments.

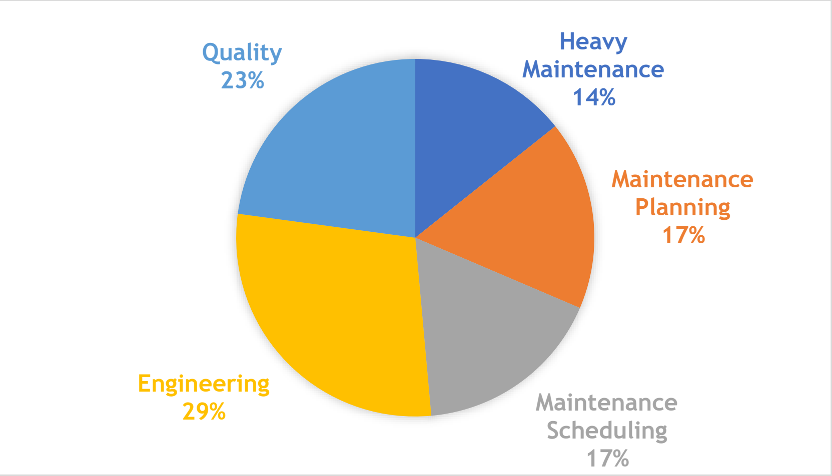

Figure 5: Status of the implementation of lean methods

4.3. Effectiveness of lean methods at South African Airways Technical

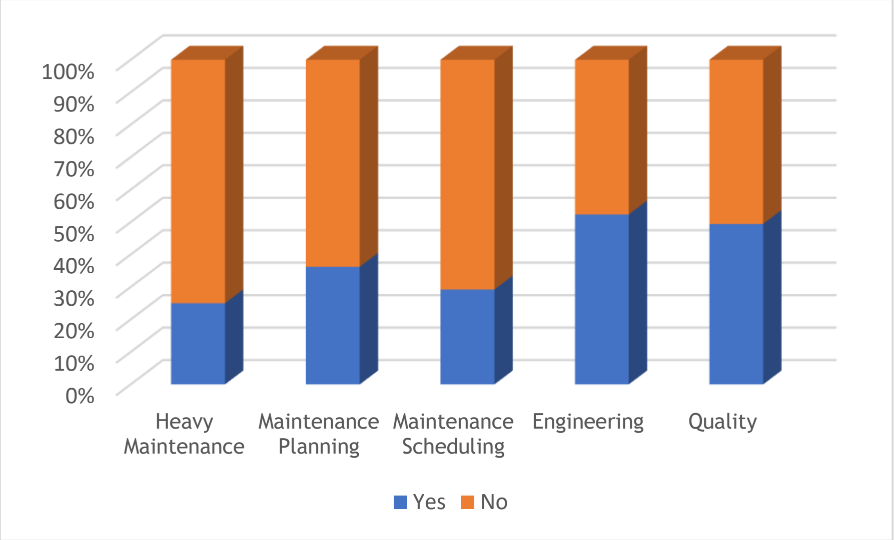

Figure 6: Effectiveness of lean methods in each department

The participants were asked if the implementation of lean methods had improved planned and scheduled maintenance. The figure above shows that the implementation of lean methods at SAAT is a work in progress and that most of the departments do not recognise the importance of adopting lean methods. Management should invest in improving the knowledge of employees working in heavy maintenance, planning and scheduling as far as the introduction of lean methods is concerned.

4.4. Opportunities and challenges encountered in implementing lean methods.

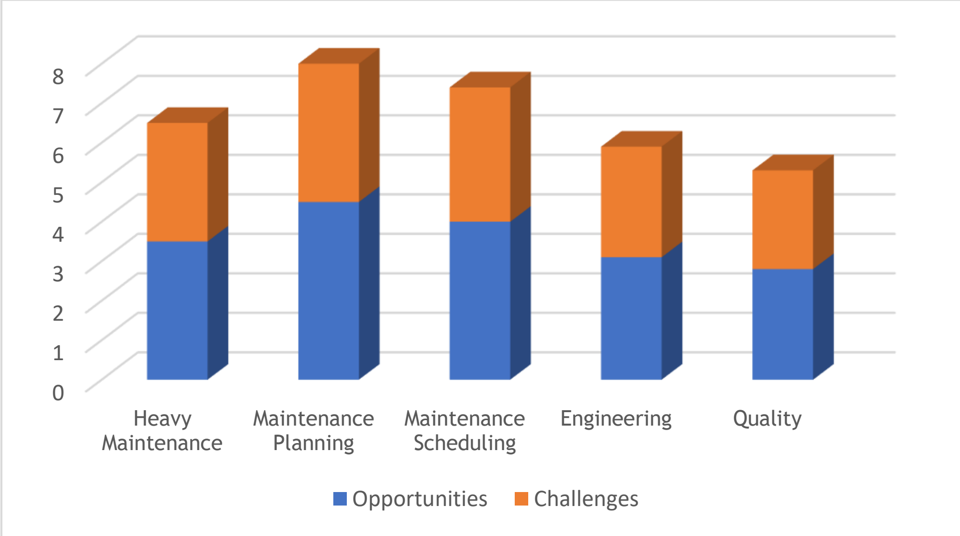

Figure 7: Opportunities and challenges

A questionnaire was used to determine which opportunities and challenges the participants had encountered during the implementation of lean methods in their perspective departments. A questionnaire was also used to assess the degree to which lean methods had been implemented.

Participants involved in heavy maintenance, planning and scheduling had an opportunity to outline what their departments needed to improve the movement of task cards. All the participants from different departments had equal and fair opportunities when it came to the implementation of lean methods with fewer challenges encountered.

4.5. Limitations of the study

The findings of this study are limited because the data that were used were sourced from international sources rather than local ones, which indicates that more research needs to be done in South Africa within the aviation industry. With respect the sample, only the heavy maintenance, maintenance planning, maintenance scheduling, engineering/quality departments and managers of SAAT were requested to complete questionnaires.

5. RECOMMENDATIONS AND CONCLUSION

The important initial step is for the management of SAAT to develop a strategy that is aligned with the company's operation and that has a clear measurement plan. Fundamentally, management are responsible for ensuring that employees are informed of and educated about the significance of lean methods. All targets that are set by SAAT management should be communicated to the entire organisation. The training and upskilling of workers must take centre stage to ensure that SAAT remains competitive in the global market. Management needs to invest in new technology and innovations to ensure the company's relevance and effectiveness.

Based on the data collected through interviews and system observation, it was concluded that the implementation of lean methods in the integration of planning and scheduling in an aircraft maintenance organisation can lead to an improvement in profitability and a reduction in grounded aircraft. Although the participants emphasised the importance of improving production, they were also concerned about their personal growth and how they would fit into the system. The introduction of a new system or new technology into the structure or the culture that already exists requires the full commitment of management so that employees will not feel left out. Furthermore, participants identified a lack of training, coaching, mentoring and skills development. This framework is explored and linked to the research results.

5.1. Future work

Companies which aim to remain competitive are striving to improve their levels of productivity, quality, and services. Lean management principles is a well-researched and successfully applied managerial strategy. Therefore, combining Industry 4.0 and Lean methods appears to be a critical evolutionary step for raising the bar on operational excellence. As is recognized from Lean methods, an increasing number of Industry 4.0 technologies are being employed to cut waste and reduce costs. In the process of continuous improvement, it's crucial to keep the client in mind and take into account how employees contribute to the value of the delivered goods and services.

ABSTRACT

The study was conducted at a plant that processes cowhide parts to manufacture leather parts for car brands. The cutting plant was not meeting the desired target per hour and only averaging only 4,1 m^2 per head/hour while the required performance was 5 m^2 per head/hour in order to meet the new demand. This resulted in a 0,9 m^2/head/hour gap in achieving the desire output, thus creating a bottle neck at the lamination process, which resulted in an inventory build-up of 18%. The main objective was to determine measures that can be implemented to improve productivity at the organisation's lamination process. The investigation through the use of industrial engineering tools, led to an improvement of at least 20% in productivity, as well as a workforce that has a greater understanding of the importance of conducting a cost-benefit analysis.

Keywords: lean thinking, industrial engineering, process optimisation

1. INTRODUCTION AND BACKGROUND

The lamination operation of the cutting plant of a leather-processing company was not meeting the desired target per hour and was not achieving good productivity. This coincided with the launch of the new car model, which had increased demand, and led to poor performance at the cutting plant. The lamination operation averaged only 4,1 square metres per head per hour (m^2/head/hour) for the period being studied. The launch of a new car model led to an increase in leather needed for the car parts. The new targets were now revised 5 m^2/head/hour. Consequently, there was a shortfall of 0,9 m^2/head/hour in achieving the desired output, thus creating a bottleneck in the lamination process. This bottleneck resulted in a build-up of 18% in inventory.

The cutting plant of the organisation is divided into two main operations, namely, a cutting operation and an enrichment operation. The enrichment operation is based on customer-driven requirements. Lamination forms part of the enrichment operation leather panels are laminated because the cut leather parts have to be married to foam cut-outs. Leather panels are fused to foam cut-outs by aligning the two components on top of each other and then feeding the panels through a lamination machine. The lamination machine uses heat technology to activate and melt the glue adhesive surface found on the foam cut-outs, which then stick to the leather panels. The process is further summarised in Figure 1 below.

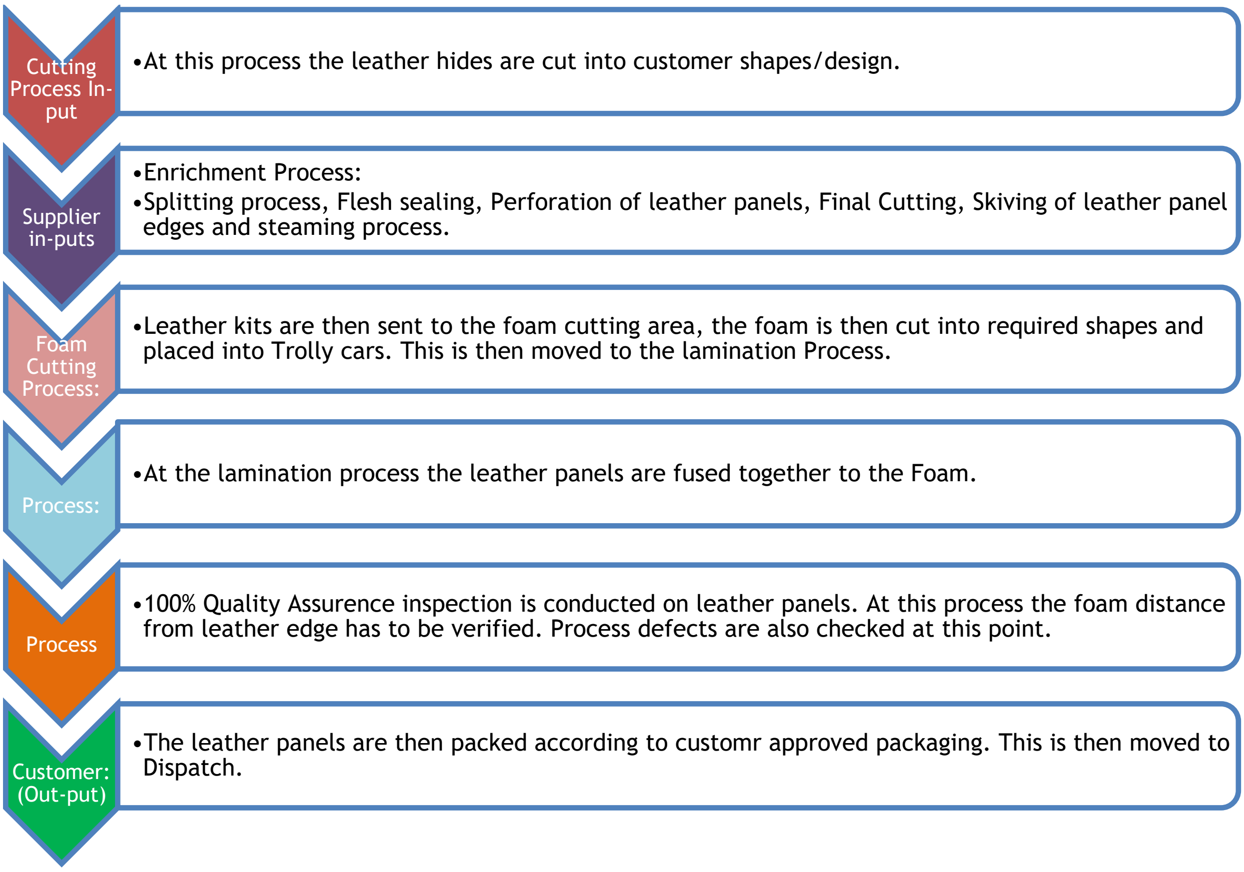

Figure 1: Lamination Process Steps summarized

Figure 2 below is a Suppliers-Inputs-Process-Outputs- Customers (SIPOC) diagram that maps the lamination process. It assists in analysing and visualising the lamination operation and ensuring that all key elements, such as suppliers, inputs, process, outputs, productivity and customers. Both external and internal suppliers and customers need to be considered when analysing the lamination process of the cutting plant.

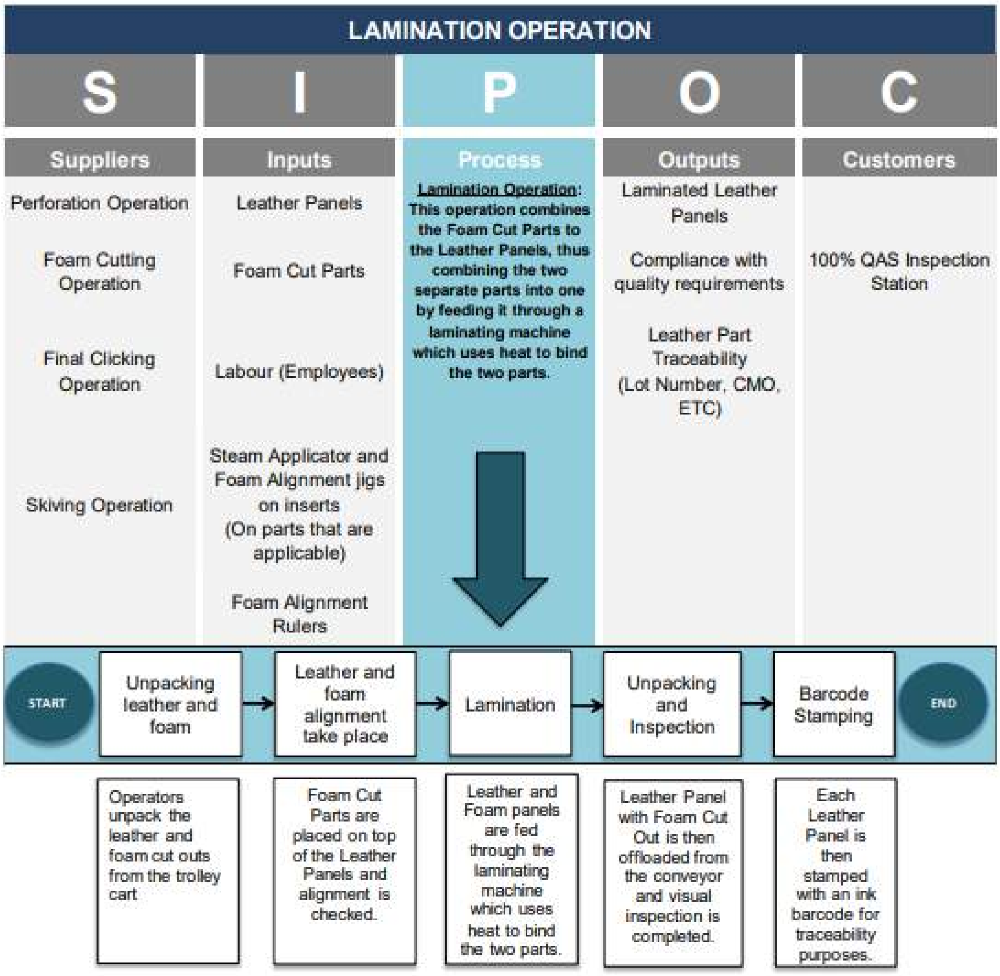

Figure 2: SIPOC diagram for Lamination Process

During the first quarter of 2022 the leather-processing company experienced an increase in demand for its products necessitating improvements in the enrichment process to ensure that products are processed in the shortest lead time. A target of 3 000 m² per day is required. The productivity of the current lamination process is 2 280 m², leaving a shortfall of 160 m² per day. This shortfall created delays in customer deliveries. At this stage, the reasons for shortfalls had not been identified. This process has many customer-driven requirements. In the lamination process, foam is fused to leather. When foam is fused to leather, customer tolerance needs to be taken into consideration. Outer nicks guide employees on correct positioning. Before the lamination process starts, an adhesion test has to be performed to determine if the leather and the foam bond well.

The main objectives which were to:

- Investigate the causes for not achieving the targeted output at the lamination operation from an average of 4.1 m²/head/hour to the desired target of 5 m²/head/hour by the end
- improve the productivity at lamination operation using lean principles
- To ultimately eliminate the bottleneck at the operation

2. LITERATURE REVIEW

Productivity is normally defined as the ratio between the output of production and the input of production factor [1]. Krueger [2] defined productivity a measure of efficiency in which resources are utilized to achieve desired outcomes and can drive economic growth and higher living standards by increasing output per unit of input. In the context of this study, it is therefore important for the company to measure and improve productivity to achieve the goals of research. This literature review focuses on the techniques and methodologies that can be implemented to improve productivity in this leather processing plant.

2.1. Lean Production and tools

Lean production can be traced to 1980's as reserachers depict the Japanese manufacturing industry's sucess, especially the Toyota Production System [3]. It can also be defined as a set of tools and technqied that assist improving customer value by focus on the reduction of wated generating activities[4]. Lean production and its principles is now widely used in many service sectors, rather than being only implemented in production. Fercoq et al. [5] defines the categories of wastes as:

- overproduction,
- waiting,
- excessive transporting,
- over production,
- unnecessary inventory,
- excess motion and
- defects

2.1.1. Plan-Do-Check-Act (PDCA) Cycle

The strategy utilized in this venture is execution of conceptualizing procedure in the organization. Under arranging period of PDCA CYCLE given by Deming the conceptualizing is finished and any remaining Len producing apparatuses recorded beneath. The PDCA cycle implies [6]

- PLAN: Design or modify business process parts to further develop results
- DO: Implement the arrangement and measure its exhibition
- CHECK: Assess the estimations and report the outcomes to chiefs
- ACT: Decide on changes expected to work on the interaction

2.1.2. Gemba walks

McClam Liebengood [7], describes gemba wallks as workplace walkthroughs which aims to examine operators, query about their tasks, and identify productivity gains. This usedful toolwas also used in this study. In this study, the study team walked the floor, made the operators understand the important and purpose of Gemba walk at lamination plant. The objective was to identify areas of improvement and achieve the targets, not to monitor or spy on the employess. The employees were informed in advance to prepare for the Gemba walk and questions that will be sked. Caution was taken to instill trasparancey.

2.1.3. 5 Why's

Melton [8] states that there is a practice of asking why five times whenever a problem was found and this way the root cause was solved rather than the symptom. During the gemba walk that was conducted, questions about the different activities that took place at lamination operation were asked. The 5 why's provide a great basis and valuable insight for the questions that were being asked. Employee input was seriously being taken into consideration. All employees shared their ideas and identified areas that needed improvement at lamination operations. Several observations were made during the walk; Managers from different departments were invited for the walk to get different points of view and fresh ideas.

2.1.4. 5S

Melton [8] further defines 5's as five activities used to create a workplace suited for visual control and lean practices and 5S is a straightforward useful methodology that conveys reasonable continuous improvement by driving responsibility to the cutting edge in your business. For this study it was explored.

3. RESEARCH METHODOLOGY

A combination of quantitative and qualitative methods was employed in the study. The researcher found it appropriate to conduct a qualitative investigation to gain a deeper understanding of the problem under investigation and to compare key factors. A quantitative study was also required since financial impacts and production processes had to be calculated.

A qualitative approach helped the researcher to grasp the problem quickly and to develop knowledge of the applicable field. A quantitative approach was followed to transform the information into relevant measurable data. Therefore, the researcher used qualitative and quantitative methods in combination by first gaining knowledge of the applicable field and then compiling and transforming the information into computable data. This methodology enabled the researcher to analyse the current process under investigation and to determine the set-up of the future process. A qualitative research design is appropriate for gathering opinions on a particular subject or when studying human and machine behaviour. The literature review section research data in this study were gathered through a secondary systematic review, which involved searching for articles on the internet. To achieve the goals of the study, exploratory research was done to define the breadth and scope of the topic.

The data collection method used at the lamination operation is semi-automated, that is to say, it is partially manual and partially automated. The data collection system at the lamination operation is considered manual because an employee has to scan the side-label barcode of each new batch for the system to collect data. The data collection system is also considered automated because information is automatically updated and converted into a square metre measurement, simply by scanning a side-label barcode. The system then calculates the square metres per net lettable area (sqm/NLA) based on formulas that have been fed into the data system. When an employee scans a side-label barcode, information is transmitted to a database and loaded into the automated Lamination Productivity Tracking System, as well as onto the company's Enterprise Resource System (ERP). The side label contains information such as the customer's name, as well as information on the applicable model, part number, packing quantities, parts and so on. The Lamination Productivity Tracking System is a database that was developed by the finance department to assist with the tracking of sqm/NLA in the lamination operation.

Before the introduction of the Lamination Productivity Tracking System, there was no defined way of tracking sqm/NLA because the ERP system proved to have limitations in providing this real-time data. In many instances, sqm/NLA could only be tracked using the ERP system once a batch reached the despatching area and was scanned into the despatching warehouse. This procedure was not beneficial for tracking progress at the lamination operation since the operators at this operation did not know if they were hitting the target until it was much too late. The introduction of the Lamination Productivity Tracking System was essential since it provides real-time data of sqm/NLA processed, simply by scanning in a side-label barcode and refreshing the system every time an update is needed. This helps employees by giving them access to real-time data, which indicates if they are behind or ahead in meeting the hourly target.

4. RESULTS AND DISCUSSION

The part of the research paper focusses on the results of the study

4.1. Performance vs expectation

A time series plot was developed in order to understand the current performance of the lamination process. This graph depicts data samples that were collected over 5 weeks, as well as the applicable customer specifications, which are represented by means of upper and lower specification limits. The graph shows whether the NLA per head per hour (NLA/H/H) falls within or outside the customer specifications as specified in Figure 3.

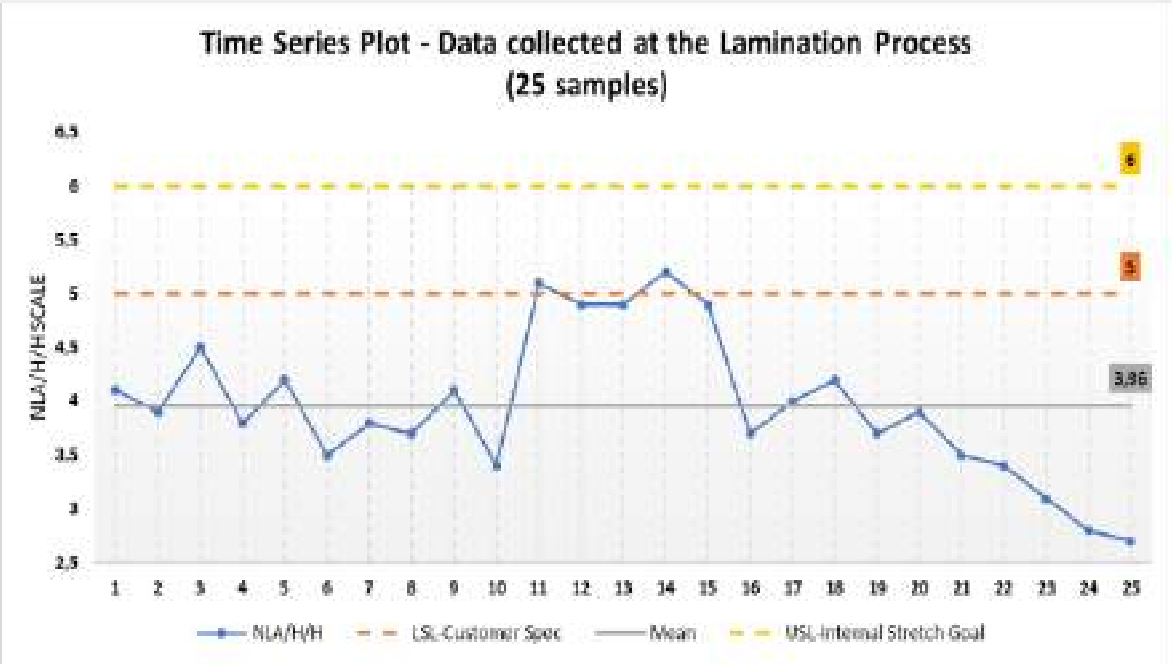

Figure 3: Time series plot for the data collected at the lamination process

An observation that can be made when looking at the time series plot is that only 2 data samples out of the 25 samples fall within the desired target range of 5-6 NLA/H/H.

In calculating the z-score on Excel, it was estimated that the lamination operation will achieve the desired target of 5 NLA/H/H only about 7% of the time. This is also depicted in the time series plot, where approximately 93% of the data samples fall below the desired target range.

Table 1: Summary of the challenges experienced in the lamination process

Lamination Operation - Cause and Effect Matrix (Key Input and Output Variables)					
		(Y) Statement: Lamination operation is not consistently meeting the average 5 NLA/H/H			
Number	Category	Root Causes Identified (X's)	Impact Score	Implementation Score	Total Score
1	Method	Production Delay- Shortage/ Extra foam parts (Only discovered once on the line)	9	3	27
2	Method	Production Delay- Wrong cuts on the foam panels (Only identified or detected once on the line)	9	3	27
3	Method	Production Delay- Mixed parts (Only identified once it is already on the line)	9	3	27
4	Method	Poor planning and scheduling at the lamination operation	3	3	9
5	Method	No defined method followed by each operator regarding task completion	9	3	27
6	Method	Misalignment reworks that cause delays during the lamination process (Currently make use of Prints for some leather inserts)	1	3	3
7	Machinery	Changeover times vary between different customer models. Different temperature settings are required on the machine	3	3	9
8	Measurement	Downtimes at the lamination operation not sufficiently being recorded	9	3	27
9	Measurement	Lamination Productivity Tracking System is temporary down due to IT complications	1	3	3
10	Manpower	Resistance towards change from how they use to doing work	3	1	3
11	Manpower	Team leaders are not effectively utilizing the Lamination Productivity Tracking system to check process performance during the shift	3	9	27
12	Manpower	Absenteeism	3	1	3
13	Manpower	Correct manning requirement for the operation	9	1	9
14	Environment	Poor 5S practiced at the lamination stations, resulting in unorganised and cluttered work stations and build up of leather panels on the lamination tables	3	9	27
15	Material	Delamination that takes place, results in panels having to be reworked	3	1	3
16	Material	Panels that are rejected at the QAS Inspection Station that have to be reworked.	1	3	3

4.2. Drivers and requirements

Based on the critical-to-quality tree (CTQ) analysis, delivery and quality play a vital role in meeting customers' needs, in this case, the quality assurance inspectors' needs. The focus is placed on the delivery function (5 m^2/head/hour) since the lamination operation is currently not meeting the customer demand.

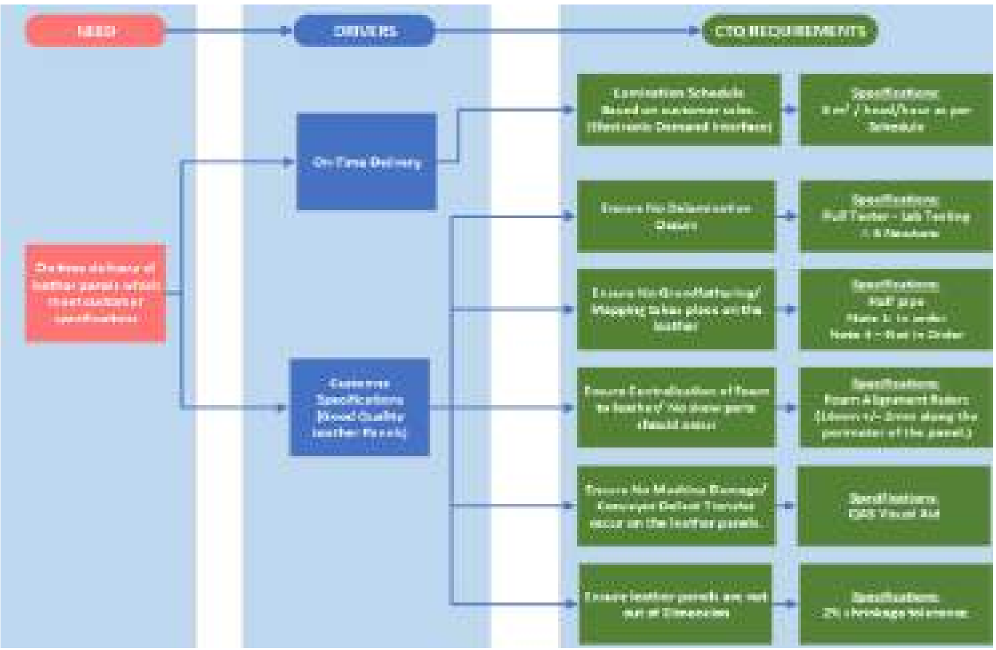

Figure 4: Driver and CTQ Requirements Analysis

4.3. Lamination productivity

Figure 5 below shows the performance (productivity) of the lamination operation at the beginning of the year. It started out well and then went down to below the target. The decline in productivity was the result of an increase in W206 lamination machine. Data thus far show that with an increase in W206 NLA, productivity decreases (scatterplot and regression analysis).

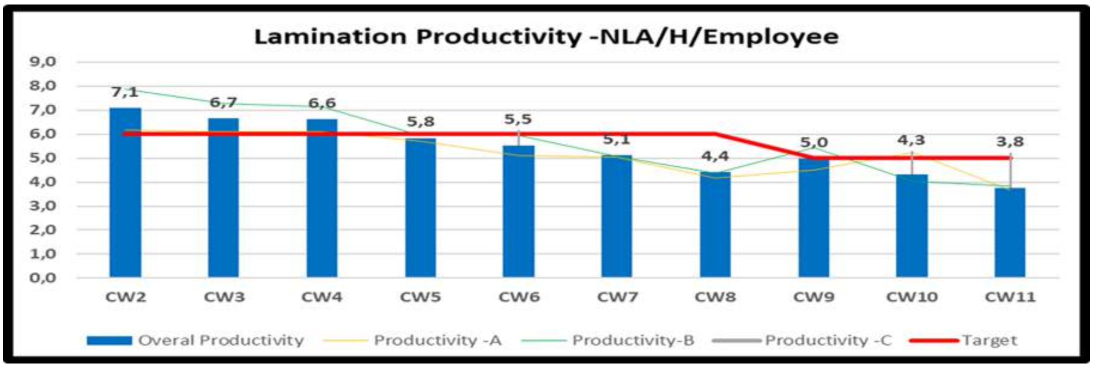

Figure 5: Lamination productivity per employee

4.4. Cause and Effect analysis

The cause and effect diagram presents the possible causes of not meeting the targets in the lamination process

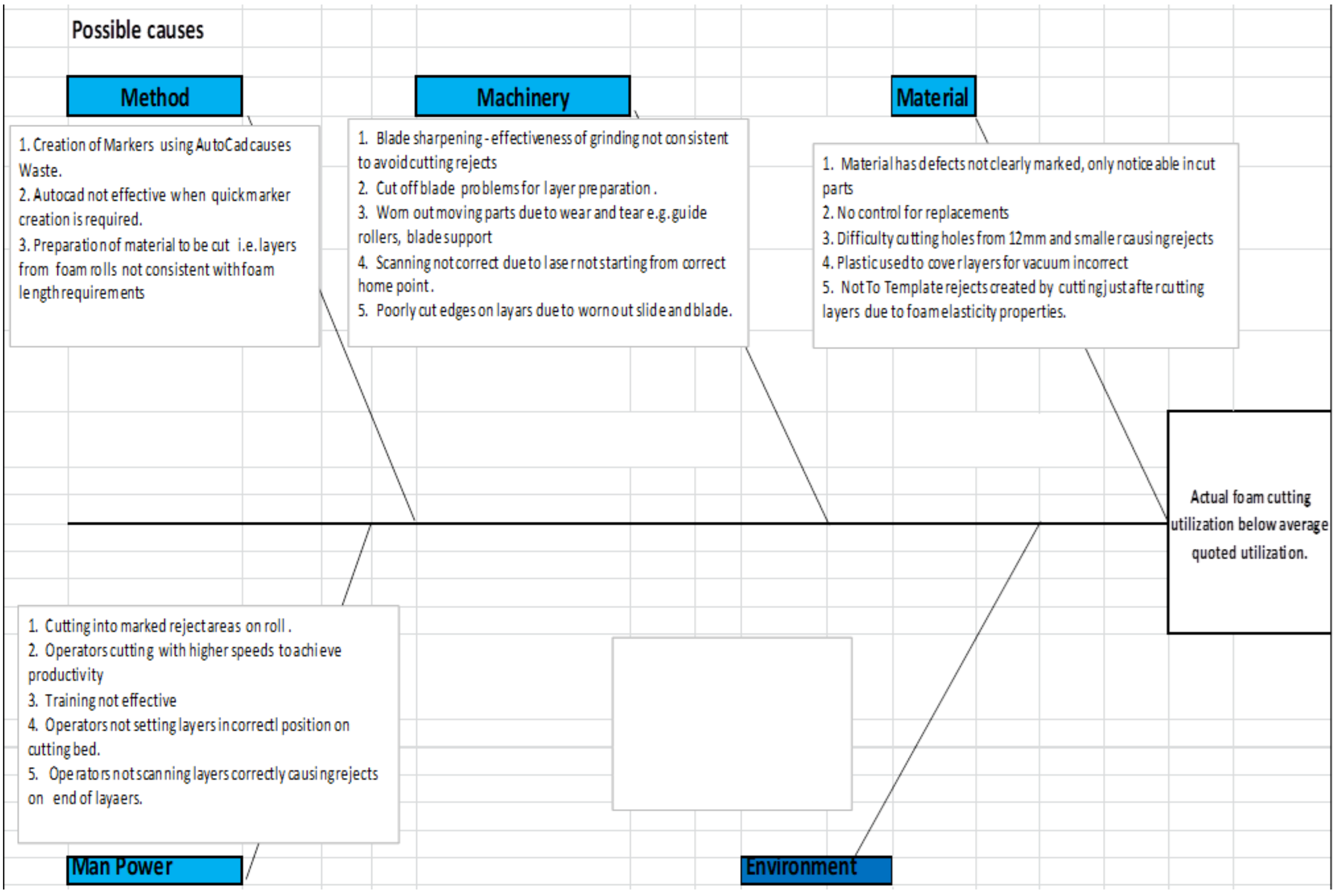

Figure 6: Root Cause Analysis

In summary, the causes and effects are summarised in Table 2 below.

Table 2: Summary of Causes and effects

Cause	Effect
Poor method of creating markers used	Low utilization causing waste
Wrong marker measurements used to cut layers	Miss-cut at the end of the roll
Cutting Speed to high	Rejects due to pieces being not to template
Layers poor aligned to the cutting bed	Miss-cuts on the far end of layers
Cutting blade not sharpened	Not to template, miss-cuts rejects cut.

4.5. Issues detected during Gemba walk

- Continuous change to the planning schedule, therefore making some makers unusable on a daily basis.
- Availability of time to change markers daily due to headcount restriction to employ a dedicated person to create markers.
- Machine related rejects such as miss-cuts can cause reduction in utilization achievement.
- Operator errors in when aligning layers can cause unwanted rejects.
- Excessive undeclared reject sections on roll by customer can affect utilization achievement.

4.6. Summary of Solutions proposed after using tools

The proposed solutions are summarised in the points below.

- Use offsite marker making software to improve markers making turnaround times.
- Train operators to improve the handling of material
- Improves and instil best practice methods to achieve the desired results.
- Combine different shapes using similar material with better interlocking shapes that leave smaller gaps between panels.
- Increase sharpening frequency by reducing distance between each between each point to reduce rejects.

4.7. Solution Selection

- Marker making using external software remotely at no cost was done.
- This helps with quick marker making process, improved utilization and cost reduction due to reduced waste.

4.8. Process performance (improved)

Once all the required solutions had been implemented, it was important for the team to determine if there was any progress towards achieving the desired goal of 5 NLA/H/H. Once all the necessary changes had been implemented and the relevant training had been completed at the lamination operation, it was time for the team to determine if any measurable improvements had taken place at the lamination operation and to quantify those improvements. The team collected data regarding the NLA/H/H achieved over a 3-week period (CW 28 to CW 30) at the operation after all improvement measures had been implemented. The diagram below shows the performance (productivity) of the lamination operation after the implementation of these measures. The productivity of the operation ended very well, reaching the target of 5 NLA/H/H.

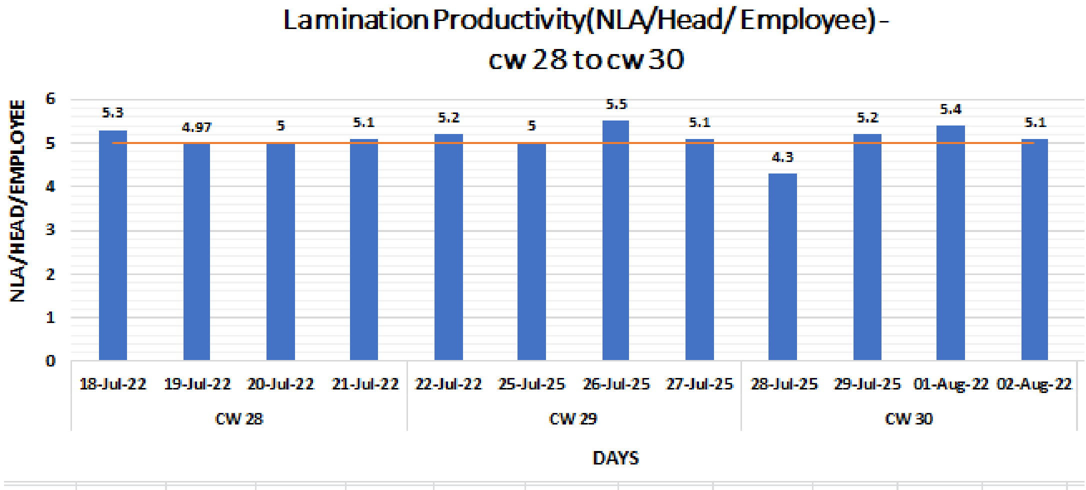

Figure 7: Lamination productivity

Figure 7 presents the results of the data collected over the period CW 25 to CW 30. The team noticed a significant improvement towards achieving the target of 5 NLA/H/H. When the team initiated the productivity improvement project at the lamination operation, the operation averaged 4,1 NLA/H/H for May. Based on the 3 weeks monitored in July, the operation averaged 5,21 NLA/H/H, which is above the desired target of 5 NLA/H/H. This was a great achievement for the operators working at the lamination operation since many of them were initially hesitant about the changes that were implemented in the work area.

5. RECOMMENDATIONS

The results of the study gave rise to the following recommendations:

5.1. Retrain employees in downtime

As identified in the cause and effect analysis, one of the major issues were operator errors in when aligning layers can cause unwanted rejects. This warranted refresher training and coaching specific topic/process that they have already encountered with the aim of jogging their memory and boosting their knowledge of the topic. This type of training is also useful for ensuring that employees have the most up-to-date information at their disposal. Refresher training is a great way to ensure that employees follow company best practices and adhere to important procedures, especially when it comes to compliance with regulations. A lack of compliance can lead to mistakes by employees and, in more serious cases, sanctions or penalties from external regulators [9].

Operators and team leaders at the lamination operation were given refresher training in downtime tracking and the importance of effectively recording any downtime that may occur at the operation. The refresher training was conducted in small groups during each shift at the lamination production boards. Downtime trackers are located at each of the production boards so that employees can update the trackers when any downtime occurs. The training was conducted by the cutting-process engineer and the researcher. The team wanted to ensure that all team leaders and operators gained a clear understanding of downtime tracking and how it affects the productivity metric for measuring NLA/H/H at the end of each shift.

Retrain team leaders and employees of the lamination operation to ensure they know how to effectively utilise the Lamination Productivity Tracking System. The production supervisors trained the team leaders in the use of the Lamination Productivity Tracking System so that they can monitor the NLA/H/H to determine if the team falls behind or is on target in meeting the hourly target throughout a shift. This training was vital because prior to the introduction of the system, the team leaders had no access to real-time data that could provide them with progress updates throughout a shift. The system gives the team leaders the opportunity and the time to implement corrective actions if the team starts to fall behind.

The final observation made during the implementation and testing phase of the improvement project was that following the introduction of a pre-lamination station and specified job tasks for each of the operators, the operator who was stationed at the pre-lamination station could not maintain the same pace as the operators who simply had to feed the line and no longer had to align leather and foam panels. Owing to a limited headcount, the team could not place additional operators at the pre-lamination station, which proved to be a challenge since the pre-lamination station created a new bottleneck. The team then came up with the idea of building buffer stock into the process in order to assist the operator stationed at the pre-lamination station. The team decided that one full packing quantity must be prepped for lamination prior to the end of a shift. This will ensure that the incoming shift will have buffer stock available and ready to be placed on the conveyor and fed through the machine.

This idea proved successful. If the operator who aligns panels at the pre-lamination station starts to fall behind and the buffer stock becomes depleted, the designated lamination team leader will temporarily step in and assist the operator to pre-align the foam and leather panels, just enough to replenish the buffer stock. During the last 15 minutes of a shift, when the operators perform housekeeping, 3 operators will start to align foam and leather panels at the pre-lamination station, thereby ensuring that buffer stock is available between the pre-lamination station and the lamination conveyor for the incoming shift; the rest of the lamination team will, during this time, continue to carry out housekeeping activities [10].

5.2. Hold daily production meetings

The cause and effect also found that there were issues with the availability of time to change markers daily due to headcount restriction and a need to employ a dedicated person to create markers. Furthermore, machine related rejects such as miss-cuts can cause reduction in utilization achievement. The daily production meetings can assist in this regard. It is important to hold a production meeting every day to discuss the day before and any issues that may need attention and to explain the targets for the day. It can be a very brief ‘stand-up meeting’ on the production floor at the start of a shift.

i. Communicate the ‘why’

It is important to communicate the ‘why’ – why it is important to work at a more efficient rate or why productivity improvements are essential for the longevity of the business – to workers and to inform them of the important role that they play in this respect.

ii. Use visual management techniques

The use of visual management techniques such as display boards with production targets and output data enables workers to track their progress against targets on an hourly/half-daily basis. Visual aids also enable different lines or sections to track progress in relation to one another. If the workers of a line or a section see that they are falling behind the other lines, they will increase their productivity to catch up, which could create healthy competition on the floor.

5.3. Changeover conducted twice within the same component owing to different lamination types

Each product type has two different foam types that require different lamination machine settings. The lamination machine setting has to be changed for the different foam types. This changeover normally takes about 4 to 5 minutes. The team decided to change the process as follows: the operator will start laminating with the first foam type and continue until the entire trolley car of this foam type is finished. At this point, the lamination machine setting will be changed to allow lamination with the other foam type. On average, the operators lose about 1 hour per shift if they change the machine setting after each foam type. There are three lamination machines, so the models are allocated to each machine. The new method gives the operators approximately 30 minutes per machine to increase their productivity.

5.4. Introduce a pre-lamination station for the foam-cutting process and start-up for success

The idea to introduce a pre-lamination station for foam cutting was based on the observation that the Q time of leather kits during this process was overlooked, reason being the time taken to complete the foam cutting of the entire trolley, the steamer can start working on the first completed trolley and if the is any (mixed parts, wrong cuts, and shortage of panels), foam concerns this can be addressed at the same time. If the steaming process takes place at the lamination machine, the operator feeding the line has to stop and rectify the error. Often, rectifying the error entails walking to the foam-cutting area to retrieve what is called a replacement foam panel. A replacement foam panel is an extra foam panel that is used to replace wrong cuts or that is used when the incorrect foam panel was supplied. Depending on how long the delay may be, the lamination operation will be idle while it waits for the outstanding foam panel to arrive. All panels that make up a kit have to be processed since the trolley cart cannot proceed to the next operation until all panels have been laminated.

Identifying these issues before the process reaches the line will resolve many of the production delays experienced at the lamination operation. Based on this observation, the team came up with the idea to relocate the pre-lamination station to the foam-cutting area. The pre-lamination station is a table that is placed before the lamination machine and that is used to pack and align leather and foam panels so that operators no longer have to do the alignment on the conveyor – all the parts are prepped at the pre-lamination station and fed directly onto the conveyor. With the introduction of a pre-lamination station, only one person is needed to feed the cut panels through the lamination machine, thus improving the 5Swithin the lamination area significantly. The additional 2 employees per machine can be moved to the steaming area, which improves the availability of material awaiting to be laminated, also allowed for the setup for success to be introduced.

5.5. Material availability at each process not defined

During the Kaizen event it was noted that not all process which feeds into the lamination process started , At the same time, this was due to availability of leather kits. Taking into consideration each process Takt time .The Q time, the team introduced a 25% availability of leather kits per process.

5.6. Rearrange the lamination work area to improve the flow at the workstation

A layout improvement was also implemented at the lamination operation to improve flow within the work area. During the brainstorming session one of the team members suggested that the pre-lamination stations be moved closer to the lamination conveyors. Placing the pre-lamination stations next to the machines eliminates the distance the operators have to walk to fetch leather and foam panels. This simple improvement allows operators to grab pre-aligned leather and foam panels and to place them directly onto the conveyors.

5.7. Redefine job tasks for operators at the lamination operation

Once pre-lamination stations were placed alongside the lamination machines and the employees received all the necessary training regarding the new changes, the new pre-lamination process was in place and the flow within the workstation was improved through 5S. With all the new changes in place, the team could start defining and outlining specific job tasks for operators at the lamination stations. This idea emerged during the Gemba walk conducted by the team.

During the Gemba walk, it was observed that there was a lot of movement within the work area. Through further observation it was noted that operators performed various job tasks/roles and that a standard job task per operator was not defined. This led to a lot of movement and chaos within the lamination area. For example, when a trolley cart had to be unpacked for a new batch, it was observed that all 3 operators would start unpacking the trolley cart simultaneously. Any operator would then scan the side label and all 3 operators would then move to the lamination machine and start aligning the foam and leather panels on the conveyor. Employees did not have specified roles, so they would perform different roles and job tasks throughout a shift. This prompted the idea to redefine the job tasks and roles of the lamination operators. It was important that the team bring structure back to the job tasks that needed to be performed. To do this, the team outlined specific job tasks and delegated these tasks to specific employees.

The team decided that 2 operators should be stationed at each lamination conveyor and 1 operator should be stationed at each pre-lamination station. The only job function of the 2 operators at the lamination conveyor would be to feed the line. The operator stationed at the pre-lamination station would unpack the trolley cart, scan the side label and pre-align and prep the leather and foam panels for the line. For the trial, an additional operator was stationed at the pre-lamination station to assist the third operator with the pre-alignment of foam and leather panels. The two operators stationed at the lamination conveyor would no longer align the foam and leather panels on the conveyor but continuously feed the pre-aligned panels.

6. CONCLUSION

The study showed that brainstorming is an effective tool if all members of a team are properly trained. Improvement of productivity and output are used to surpass sales turnover by utilising all available resources. In this study, PDCA, A3 a Gemba walk, 5S and a time study were used to improve the quality hence productivity. In this study, brainstorming led to the use of various techniques to improve productivity and reduce the cost of machining with quality control. Improving productivity and output does not mean that people should work harder; instead, it means that they should work smarter, use better tools, techniques, processes and resources and implement new ideas.

Moreover, everyone in a company is responsible for bringing about and maintaining an improvement in output and productivity. Productivity and output go hand in hand – they cannot be separated. Teams must work hard to improve productivity and output if they are to achieve positive results continuously. The study further showed that the PDCA cycle, coupled with the brainstorming technique, is an effective tool for improving productivity with quality control.

ABSTRACT

Traffic flow is characteristically random. The traffic demand measured against the design capacity of a road section yields the efficiency of the respective section. Road section capacity and demand are random variables. Road capacity varies as prevailing driving environmental conditions subject to the maximum design limits. Demand is a function of time and associated economic activity. The quantitative performance analysis of key road traffic junctions is important for planning and decision support purposes. We apply stochastic modelling techniques to measure and analyze the traffic flow characteristics of a problematic junction in order to determine the quality of traffic flow. The delay costs associated with the junction are determined. The results form the basis for subsequent interventions on junction long term use and/or redesign.

Keywords: Stochastic Modelling, Traffic flow, Transport Systems, Traffic Congestion

1 INTRODUCTION

Road vehicle transport networks facilitate communication, trade and global supply chains. Economic activities are heavily reliant upon efficient road networks. In traffic network design, arterial roads bear the predominant, they connect important urban centers of activity and residential neighborhoods [2]. To facilitate traffic flow and enhance safety, it is necessary to control the interaction and sequence of vehicular traffic from different approaches. The inherent stop-and go movement pattern on traffic, results in significant bottleneck and possible congestion.

Intersections are an integral part of road network geometric designs [2]. Intersections arise when two or more roads merge at the same elevation. Opposing streams of traffic compete for space and time at an intersection, giving rise to a traffic bottleneck. Traffic control is necessarily a critical design factor on busy intersections. Intersection performance is determined by signal timing plan, turning movement traffic demands, traffic stream composition, pedestrian volumes, intersection geometry, temporal variation in traffic demands, driver behaviour, weather, road surface conditions, and visibility. To effect control and informed decisions, it is important to measure, estimate and monitor these parameters over time.

Traffic congestion may be considered as excess vehicles on a portion of roadway at a particular point in time resulting in reduced travelling speeds and extended traverse time [2]. Traffic congestion and consequent delays results in driver frustration, missed delivery due dates, compromised economic productivity, increased CO_2 emissions and higher fuel consumption [3]. Vehicular traffic volumes have increased considerably in and around Johannesburg. The road network infrastructure is under considerable strain, as evidenced by noticeable congestion on most arterial roads.

The lifespan of road network infrastructure may be considered indefinite. The use patterns of such infrastructure evolve significantly over time. Upgrades, re-designs, and possible re-purposing may become necessary over time. The respective decisions are a function of accurate data and information on prevailing and forecast use patterns. Traffic counts are critically important in this regard. We analyse the traffic flow patterns at an important road junction in South Africa in order to inform policy on current use state relative to original design capacity.

Traffic volumes through an intersection varies considerably with time of day. The stochastic variation of vehicle arrivals at an intersection assumes the Poisson distribution [4]. This is however regulated applying the peak-hour volume analysis method.

2 LITERATURE REVIEW

Three parameters namely, volume, speed and density describe traffic stream characteristics [5]. Volume is a count of vehicles that pass a point on a highway during a specified time interval [5]. Traffic volume is generally used to determine tally and classifications of roadway vehicles at a given location at a specific time. Accurate information on traffic volumes is vital for maintenance, design and capacity planning purposes. Rate of flow is defined as the rate at which vehicles travel through a particular point on the highway segment [6].

Traffic counts are carried out to determine the quantity, movements, and classifications of vehicles in a specific area [7]. These data can be used to detect crucial flow times, assess the impact of big vehicles or pedestrians on vehicular traffic flow, or track traffic volume changes [8]. The duration of the sample interval is determined by the type of count being performed and the intended use of the data captured [9].

Traffic volume study is performed to find the number of vehicles passing per hour, day, week, month, and year. It is generally used to determine the number of movements and classifications of roadway vehicles at a given location at a specific time and note other related traffic characteristics (composition, flow fluctuations etc.) [7]. Accurate information on the amount of traffic on the roads is vital for the planning of both road maintenance and improvement policies [7]. Traffic volume network analysis helps in deciding/planning if there is need for improvement, expansion in terms of construction missing links, by-pass, alternative road etc [7].

There are two main traffic counts methodologies, being manual and automatic count. The manual count method of collecting traffic flow data is the most prevalent, and it consists of assigning someone to record traffic as it passes [8]. This technique of data collection is labour-intensive, yet it is required in most circumstances when cars must be categorized with several moves recorded independently, such as at intersections. Traffic should be tallied and recorded individually for each movement at an intersection [8]. It is critical that traffic on roads with more than one lane be counted and categorized according to traffic flow direction [8]. Permanent traffic-counting teams are often established to do the counting at various places around the road network at predetermined intervals. The duration of the count is set prior to the start of traffic counting and is decided by the purpose of collecting data.

The automatic count method uses traffic detectors to count vehicles without any human involvement. The most commonly used detectors include inductive loops, pneumatic tubes, weigh-in-motion, and video camera [8]. The inductive loops and pneumatic tubes are placed on top of the road surfaces and when a car passes over the loop, the magnetic field changes, which activates the counting device. The automatic count approach allows for the collection of large volumes of traffic data. The traffic counts are taken at 1-hour intervals for each 24-hour period [8].

Performance of other road network service facilities can be evaluated using additional indicators e.g delay and queue length [5; 6]. Queue lengths are commonly found wherever customers arrive randomly for services [10]. Queue length affects quality of traffic flow and it is an important performance measure.

Traffic flow characteristics, specifically vehicle interweaving, frequent lane changing and the geometric deficiencies degrade traffic flow efficiency [11]. Gartner and Wegner [12] employ cellular automaton microsimulation model to study traffic flow behaviour on a signal-controlled arterial street. The model is used to analyze arterial traffic throughput and travel times for various densities and signal spacings. Ali et al. [13] evaluated the performance of traffic flow at a signalized intersection. The parameters used to assess the performance of the traffic flow included delays, operating cost, fuel consumption, and carbon dioxide emission The results showed that the level of service was low, resulting in low speeds and lots of delays during the evening and morning peak hours.

Gunes et al. [14] used the queuing theory to determine the characteristics of traffic flow. Arrival rate, traffic intensity, average number of cars in queue, and service rate were all determined using M/M/1 model Their results show that the new model results were found to be better and the mean tail length and lost time values were lower. Quan et al. [15] analysed traffic flow characteristics at a signalized intersection. The characteristics analyzed are speed, delay, and flow rate. It was found that traffic flow is normally large during evening peak hours.

Urban road junction traffic patterns are vital in traffic monitoring and accident prediction, and so play critical roles in urban traffic management [16]. Understanding traffic dynamics and diagnosing traffic congestion require the identification of spatiotemporal traffic patterns in urban road networks [17]. Such knowledge can help traffic management organizations enhance traffic control strategies, improve traffic infrastructure, and reduce congestion from a macro viewpoint [17]. Existing studies either assume static traffic patterns or a multi-variant distribution model for junction traffic levels [16].

3 METHODOLOGY

We seek to characterise traffic flow through a specific road traffic intersection in Johannesburg. The methodological approach adopted is descriptive quantitative research. Systematic traffic counts were conducted at the selected intersection, based on relative severity of congestion at the intersection. Secondary data is presented and analysed. The respective research output will offer an objective evaluation of intersection service level performance and ultimately feed into a grand traffic flow optimisation model.

3.1 Site Selection

The aim of this study is to analyse the traffic flow characteristics at a signalized intersection. The intersection under study is extremely busy, with a history of peak period congestions; and therefore viewed as problematic. It is a four-legged signalised one-way intersection with three lanes from each direction. The intersection is illustrated in figures 1 and 2 below.

Figure 1: William Nicol Drive and Leslie Avenue intersection

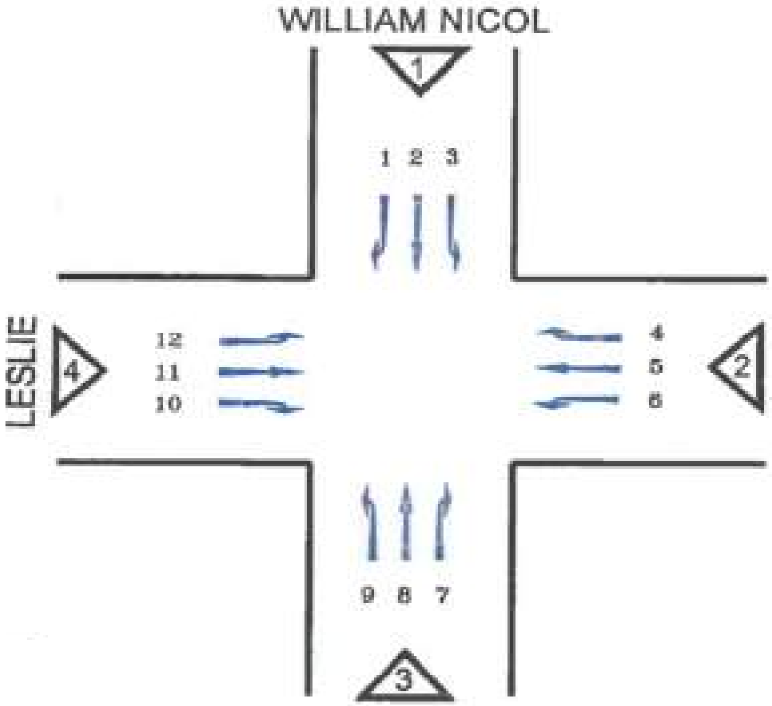

Figure 2: William Nicol and Leslie Avenue intersection

3.2 Data Sets

We apply secondary data to accomplish the objective of the study. Geometric properties were recorded on site.

The study was conducted under normal fair weather conditions. The tally reflected all vehicle types irrespective of class. Pedestrians and non-motorised cycles/vehicles are not included.

The pick hour traffic volume analysis methodology was adopted. The output data was statistically analysed. Traffic volume counts are typically stochastic, generally following the Poisson distribution. Ultimately, the estimation problem arises. To solve this problem, a hybrid of the two scenario generation methods, the sampling and deterministic methods, is applied.

There is a need to establish a finite number of scenarios. The estimation problem arises. Two scenario generation methods can be used: (i) the Sampling method and (ii) the Deterministic method. We integrate the two.

For modelling purposes, the expected value is given by:

$$g = E[(v)] = E\,[\,G(v_1 \ldots v_N)], \qquad (1)$$

Where;

g = a random variable, the volume of traffic recorded

The expected value is given by;

$$g_N = \frac{1}{N} \sum_j^N G\left(X^j\right), \quad \text{as } N \rightarrow \infty, \qquad (2)$$

Where

$X^j = \left(X_1^j .. .\, .X_N^j\right)$, is a vector of N independent identically distributed samples of v, As N approaches infinity,

$$lim_{N\to\infty}\, g_N \;=\; E\,[\,G(X)],\, with\; probability\; 1, \qquad \textbf{(3)}$$

Therefore,

$$E[g_N] \;=\; E\left[\frac{1}{N}\sum_j^N G\left(X^j\right)\right]$$

$$= \frac{1}{N}\sum_j^N E\;\left[G\left(X^j\right)\right] \qquad \textbf{(4)}$$

As sample size increases, the expected value of traffic volume in any direction approaches the mean value of the distribution in that direction.

With respect to the deterministic method, the distribution is approximated by a small number of discreet points. We select two discreet values to approximate the demand distribution, the expected value as determined above, and the highest recorded value.

4 RESULTS AND DISCUSSION

4.1 Summary of traffic counts

Table 1 below presents the summary of traffic counts. It shows the volume recorded during the peak hour for both morning and afternoon peak, for all movement directions. The peak hour factor (PHF) for each movement is presented.

Table 1: Summary of traffic counts

MOVEMENT		AM PEAK HOUR		PM PEAK HOUR		6 Hour Count
		Vol	PHF	Vol	PHF	Total Vol
North bound	NR	76	0.88	81	0.95	429
	NT	2457		2531		12101
	NL	99		55		499
East bound	ER	84	0.86	113	0.94	587
	ET	87		111		542
	6EL	427		251		1519
South bound	SR	192	0.88	264	0.94	1109
	ST	2608		1454		10871
	SL	120		708		1849
West bound	WR	682	0.97	123	0.77	2138
	WT	133		74		495
	WL	94		77		378
TOTAL		7059	0.94	5842	0.96	32517

The peak hour factor (PHF), which measures how steady traffic flows during peak hour and compares the total traffic volume during the peak hour with the traffic volume during the busiest 15-minutes of the peak hour is given by:

$$PHF = \frac{Peak\ Hour\ Volume}{4 \times Highest\ 15\ minute\ Volume} \quad (5)$$

4.2 Traffic counts

Manual Traffic counts are done by surveyor(s) who record traffic as it passes. Data is collected by using hand tally and/or manual counters. A tally sheet is designed with the first column allocated for selected time intervals. To minimize error, two or more surveyors are assigned per direction of movement. A vehicle is counted and recorded on a tally sheet as a tick as it approaches or passes the traffic signal. A stopwatch is used for measuring the count intervals.

The sample graphs presented below show the typical hourly traffic volume for morning peak, 06:00am – 09:00am and the afternoon peak, 15:00pm – 18:00 pm. in a specific direction. The graphs are produced for all traffic directions recorded.

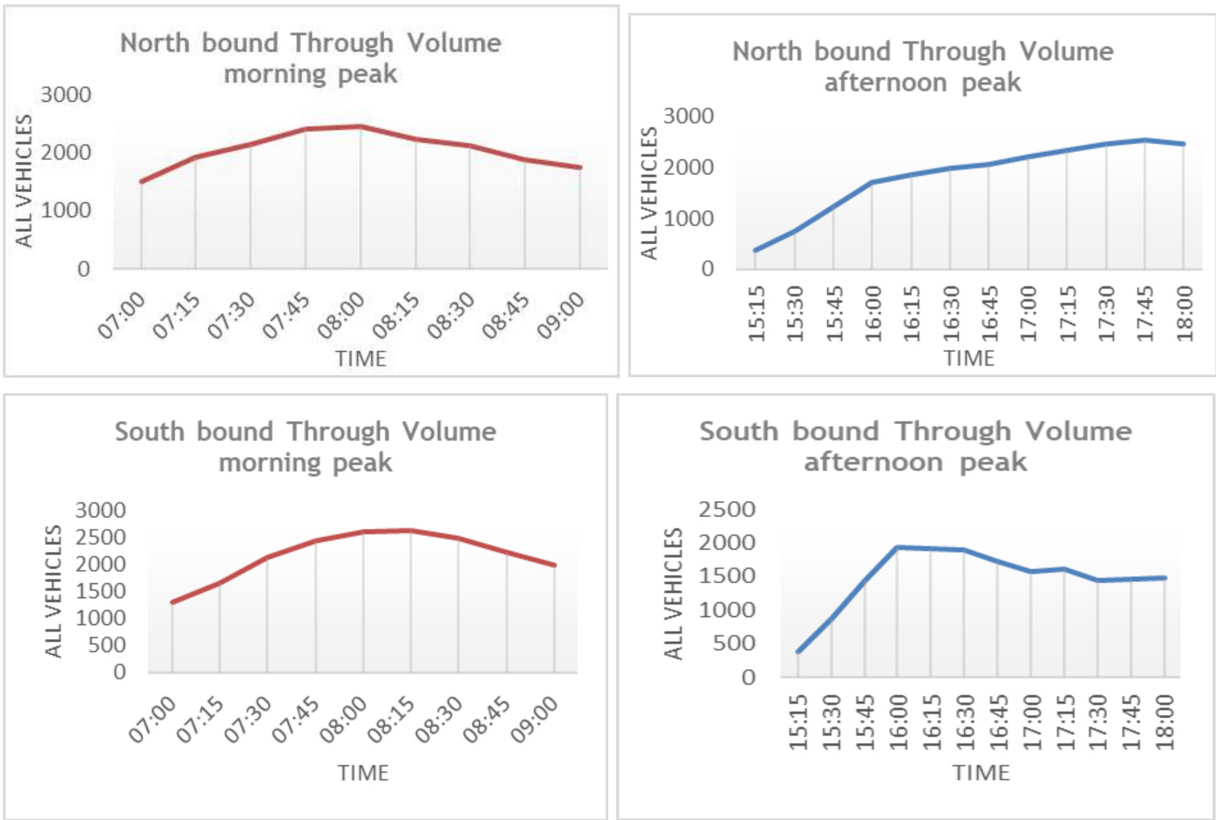

Figure 3: Traffic volumes

4.3 Descriptive statistics

Table 2: Descriptive statistics

Volume Count	Mean Veh/hr	Standard Deviation	Co-efficient of Variation	Observation	Maximum (Veh/hr)	Minimum (Veh/hr)	Number of Lanes
North bound (R)	71	21,46	0,3022535	21	104	30	3
North bound (T)	1925,048	568,3	0,2952134	21	2531	368	3
North bound (L)	80,86	26,27	0,3248825	21	112	16	3
East bound (R)	95,48	29,84	0,3125262	21	135	29	3
East bound (T)	91,24	32,79	0,3593819	21	132	21	3
East bound (L)	250,67	110,62	0,4412973	21	437	26	3
South bound (R)	185	65,91	0,3562703	21	276	44	3
South bound (T)	1768,09	557,72	0,3154364	21	2614	384	3
South bound (L)	297,43	257,12	0,8644723	21	719	44	3
West bound (R)	333,38	282,06	0,8460616	21	699	22	3
West bound (T)	81,43	29,03	0,3565025	21	133	16	3
West bound (L)	62,05	24,94	0,4019339	21	97	7	3
Overall Average	436,8065	167,1717	0,4313527		665,75	83,91667	

Table 2 shows the hourly traffic volume statistics for all directions evaluated. The North bound through traffic recorded a count of 1925,48 veh/h on average. The South bound through traffic recorded the highest maximum of 2614 veh/h. This correlates with the fact that major economic hubs are situated North of the intersection. The East bound and the West bound through movements are relatively low.

The North bound through direction has the highest standard deviation of 568,3 which indicates that the traffic volume traversing in this direction has wider spread. The turning movements (all directions) have a low standard deviation, indicating that the traffic volume is clustered around the mean.

There is variation in the peak hour volume that occurs at the intersection. The coefficient of variation (CV), which is calculated as the ratio of the standard deviation over the mean, can quantify this variance. The CV varies from a minimum of 30% to a maximum of 86% and on average is equal to 43%.

4.4 Determination of correlation between the direction of movement

Some correlation between movement directions was established. It is established that the South bound through movement has a high correlation with the north bound right turning movement. The higher the volume from both directions, the higher delay is experienced.

5 CONCLUSION

The objective of this study was to examine the traffic volume at the intersection under study. The aim was to establish traffic counts in different directions of movement and degree of congestion. This will assist in formulating demand management strategies and consequently reduce delay, queue lengths.

The results show that the demand is higher in the North bound and the South bound direction through movements. This means that more green time should be given to this direction by the traffic signal. This will allow more vehicles to pass in order to reduce the queue length and the waiting time for these motorists at the intersection.

The congestion and consequent delays negatively impact road users. Excess time is wasted in traffic, adversely affecting productivity, delivery due dates and generalised economic activity.

ABSTRACT

The emergence of the Fourth Industrial Revolution (4IR) phenomenon has engendered a heavy dependency on integrated data & information systems and technologies by companies for effective day-by-day functioning of their operations. This is because 4IR phenomenon introduces intelligent networking of machines and processes for industries with the help of information and communication technologies, as it connects the physical, biological and the digital world. As a result, there arises a need for an alignment of Data & Information Management approaches with the organizational strategic plans for adoption and implementation of the 4IR technological innovations. The main objective of this paper is to outline data and information management in the context of 4IR phenomenon and exhibit the criticality and the influence of data and information management in 4IR technological innovations. The research methodology includes qualitative, exploratory, descriptive and integrative literature reviews. The study also proposes an information management model for the adoption and implementation of Fourth Industrial Revolution technological innovations.

Keywords: Information Management, Fourth Industrial Revolution (4IR), technological innovations, integrative literature review, technology adoption and implementation.

1 INTRODUCTION

The advent of the Fourth Industrial Revolution (4IR) phenomenon has brought with many transformative technologies, which allow for the creation, generation, collection, analysis and dissemination of data and information to relevant stakeholders. These 4IR data and information enabling technologies include big data, analytics, cloud computing, 3D printing, drones, internet of things and others. However, these transformative 4IR technological innovations have created complexity in managerial decision making at the time when agility in decision making is critical.

The adoption and implementation of 4IR technological innovation involves elicitation, archiving and processing of very large data sets with the application of big data techniques [1]. It has been posited by [2] that one of the drivers of 4IR technological innovations is the large quantity of data that companies' need to process. According to [3] processing of large amounts of data, streamlining of operations and data transparency are some of the critical drivers of 4IR technological innovations.

According to [4], information management and information technologies are critical for the success of business as they directly affect the mechanism through which they create and capture value. It has been highlighted by [5] that data management is crucial for the creation of an environment where data can be useful across the entire organization.

Information flow is critical for 4IR technological innovations as the level of integration is relatively higher than in the preceding revolutions and 4IR phenomenon is characterized by data-based services. It has been postulated by [6] that 4IR technologies enable smarter and connected products that can generate, capture and share data.

As posited by [7] speed in sharing information that becomes the basis of decision-making, actions or other important activities taken by a customer, supplier or partner has become a major source of competitive advantage for many companies. It has been concluded by [8] that data resource in an organization is an essential asset that must be explicitly and professionally managed and requires a joint effort by both IS professionals and business managers.

According to [5], effective data and information management require business managers who are concerned about data, view it as an important asset and therefore establish a management system that treats it as such. It has been observed by [9] that businesses seeking to manage data and information effectively must understand how data information differ from other resources and what those difference imply.

There are various reasons that drive companies to embark on the 4IR technological innovations, amongst them is to reduce the cost of exchanging data and information and for executing various transactions [2], [10], [11], [12], [13], [14], [15], [16], [17].

Improved data and information and the need for shorter time delays have also been cited as one of the key drivers for adoption and implementation of 4IR technological innovations [18], [19], [20]. However, companies are faced with a challenge of having to process large amounts of data in order to improve / increase organizational competitiveness [2], [12], [21], [22], [23], [24].

One of the key aspects identified by many authors as a key driver for companies to adopt and implement 4IR technological innovations is acquisition of data for decision -making [25],[26]. It has also been established that one of the main challenges facing organizations when adopting and implementing 4IR technological innovations is data and information management [25], [27], [28]. Thus, it is critical for the organizations adopting and implementing 4IR technological innovations to have a tactical approach for data and information management.

As posited by [29], with the advent of 4IR technological innovations, it has become difficult to form organizational practices on how to use available data, who takes ownership, and how to set-up these workflows and governance structures. Secondly, the integration of several systems where data is stored is a challenge in many companies and the management of data and information across organizational and regional is generally unsatisfactory.

Due to the relative novelty of the 4IR technological innovation phenomenon, and complex integration of data and information amongst multiple information platforms, there is still emerging but inadequate scholarly work outlining data and information management approaches for 4IR technological innovations. Because all the previous studies related to the Data and Information Resource Management were conducted before the ubiquity of the 4IR technological innovations, a new domain specific model is required that can support data and information management planning for the 4IR epoch.

To fill this gap, this paper introduces a complementary domain specific Data and Information Management model for supporting adoption and implementation of Fourth Industrial Revolution technological innovations.

It is against this backdrop that this research paper considers setting a direction for data and information management by proposing a technology management-based approach for data and information management for the 4IR epoch.

The main objectives of this research study are to.

1. Understand and exhibit the importance and influence of information management on the adoption and implementation of 4IR technological innovations.
2. Highlight the strategic criticality of information management in the 4IR epoch.
3. Propose a data and information management resource planning approach for adoption and implementation of 4IR technological innovations.

This paper comprises a brief description of the research methodology used, integrative literature review, the findings and a discussion against the objectives and research questions, proposal of the data and information management model, conclusions and recommendations for future work.

2 RESEARCH METHODOLOGY

In line with the breadth of our research questions, the research methodology used for this study is a combination of an integrative literature review as well as an exploratory approach. These research methodologies were chosen in order to (i) provide a better understanding of the data and information management in Fourth Industrial Revolution epoch while highlighting the strategic criticality of data and information management, and (ii) propose a framework to be used for data and information management in 4IR technological innovations.

An integrative literature review as a non-experimental design in which objective critique, summary and conclusions on the selected subject is done through a systematic search, and analysis of both qualitative and quantitative means [30]. The integrative literature review focused mainly on peer-reviewed papers (both in research and practices) pertinent to 4IR / Industry 4.0 / digital transformation, using the following research databases, AIS Library, Business Source Complete, ScienceDirect, Scopus, Google Scholar, JSTOR, Web of Science, IEEE Xplore, EBSCO, Directory of Open Access Journals (DOAJ).

As postulated by [31] exploratory studies are useful where not enough is known about the subject of interest. It has also been highlighted by [32] that exploratory studies are valuable means of understanding what is happening, to seek new insights, to ask questions and to assess phenomenon in a new light.

To achieve the objectives of the study, the following research questions were addressed in the study.

1. What is information and data management in the context of Fourth Industrial Revolution?
2. Why should companies regard information management as a strategic element for the adoption and implementation of Fourth Industrial Revolution technological innovations?
3. What is the proposed approach for data and information management for the Fourth Industrial Revolution technological innovations?

3 INTEGRATIVE LITERATURE REVIEW

The integrative literature review focused on answering the two main research questions, data and information management in the context of 4IR technological innovations, and the strategic element of data and information management in 4IR technological innovations.

3.1 What is data & information management in the context of 4IR technological innovations?

The Fourth Industrial Revolution is described as a new industrial age characterized by the extensive use of advanced resources of data, information and communication technologies [33], [34]. Several authors view 4IR to be mainly about the technical integration of Cyber-Physical Systems (CPS) in the value chain [35], [36].

The 4IR phenomenon is being regarded as a data-driven paradigm because it makes better use of data to create more value hence many 4IR technologies are in some way related to data [37]. As postulated by [38], the fundamental approach in 4IR technological innovations is the real-time availability of all relevant information through the integration of all objects in the value chain and the capacity to determine the optimal value flow at any time from the data.

As postulated by [39], 4IR is the basis for data-based value creation, innovative business models, and agile forms of organization. However, the interpretation of these data sources still requires manual data analysis by human experts using various digital data visualizations and data and information management tools.

Data and information resource management has been defined as a comprehensive approach to planning, organising, budgeting, directing, monitoring and controlling the people, funding, technologies and activities associated with acquiring, storing, processing and distributing data to meet a business need for the benefit of the entire enterprise [40]. Important to note is that this definition came to the fore prior to 4IR phenomenon's ubiquity, thus its susceptibility to the 4IR epoch may require complementation.

The 4IR is about mechanisms that promote connectivity between machines, smart production and systems as well as integrated solutions [41], [42]. In other words, the essence of the 4IR is generation of large and complex amounts of data, usually referred to as Big Data.

According to [43] 4IR technologies foster the generation of data. As argued by [44], companies' connectivity, physical/ virtual joint functioning, interactivity, interoperability, self-organization, smart decision making, and others, are fundamental to fostering 4IR potential. The 4IR is about a Smart factory paradigm [45], [46], which essentially is the integration of physical and digital worlds through creation of smart products and processes capable of transforming the conventional value chains of cyber-physical systems [47].

According to [48], 4IR highlights the impact of IT on organizational structure, routines, information flow, and organizational capabilities to accommodate and adapt to IT. Essentially the technological root of IT and the alignment between IT and business become critical. It has been established that compatibility, integration and interoperability of ICT systems [21], integration between multiple information platforms [13], [21], [22] are some of the core context parameters for 4IR data and information performance characteristics.

It has been identified by [43] that availability of data is one of the building blocks of 4IR technological innovations. Data and information management in 4IR epoch, should fit with the SMACIT approach [49], which stands for social, mobile, analytics, cloud and internet of things.

Data and information management in the 4IR epoch means communication within the organizations whereby the organization's intention is to build networks for knowledge sharing and information sharing [50], [51], [52].

Other authors such as [53], view 4IR as a paradigm within ICT and proposed a conceptual framework based on business data exploitation. Digital security and compliance are part of the leading 4IR data and information management parameters [50], [51], [54], simply because companies operating in the 4IR epoch are excessively exposed to cyber-security threats and to protect their business are expected to take appropriate measures to counter the cyber-threats.

According to several authors [55], [56], data ownership and privacy (i.e., the rights and control over data) are highly relevant factors in determining competitive positioning and elements of an organization's data and information strategy.

Data and information management in the context of 4IR technological innovations encompasses at least, information environment, information context, information systems and information retrieval. Figure 1 exhibits that data and information management comprise of, amongst other parameters, data and information systems, data and information contexts, data and information environment and data and information retrieval. Data and information environment as applied in the 4IR technological innovation, refers to the distributed, complex and heterogeneity, end-to-end integrations of value chains concomitant with 4IR phenomenon.

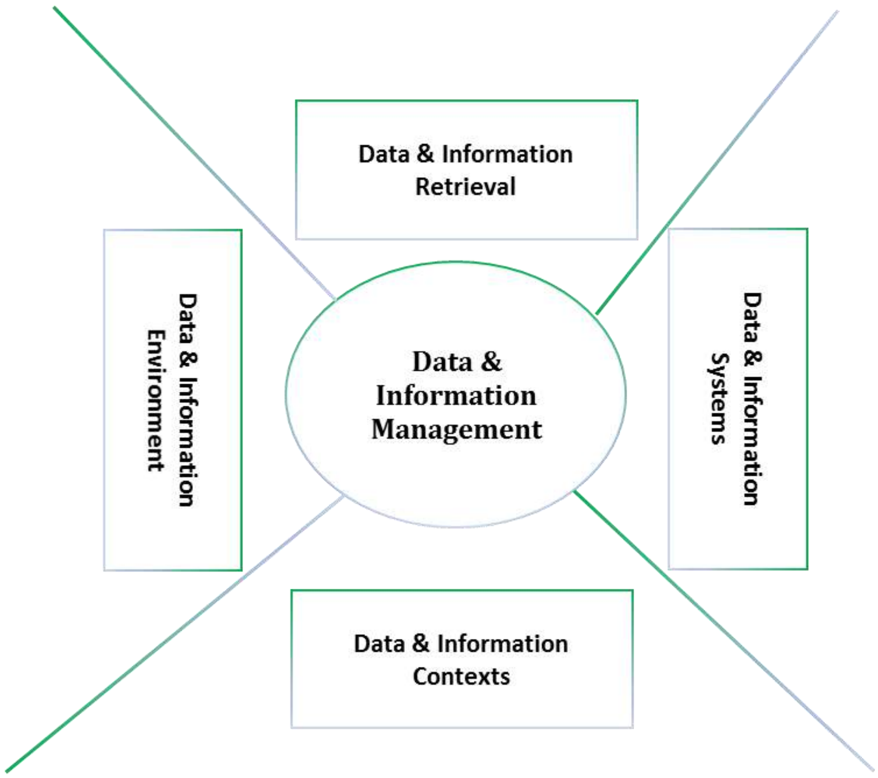

Figure 1: Data and Information Framework (Adapted from [92])

With regard to data and information retrieval, it refers to the effectiveness of retrieval performance characteristics. This is particularly important since data and information collected for 4IR technological innovations is used for agile decision making.

Data and information management systems refer to designs, implementation and usage of computer based data and information systems.

3.2 Why should companies regard data & information management as a strategic element for the adoption and implementation of 4IR technological innovations?

According to [95], strategic elements have some of the following dimensions (amongst others), require top management decision, require large amounts of company resources, affect long term prosperity of the company, has multifunctional consequences, and is affected by the company's external environment. These dimensions are fully applicable to the adoption and implementation of 4IR technological innovations, which are about the profound changes taking place in society and industries through the use of digital transformation [96], [97].

The emphasis on the criticality of data has been an issue of discussion by scholars and technology practitioners for some time. It has been concluded by [98] that the data and information revolution affects companies at least in three vital ways, namely:

- It changes the industry structure and ultimately alters the rules of the competition.
- It creates competitive advantage by giving companies new ways to outperform their needs.
- It spawns whole new business often from within a company's existing operations.

Data and information have unique properties which make them important resources for all industries, such as: Data & information are inexhaustible resource [37] and have extensive application [99]. While data and information are core resources, it is also important for companies to possess an infrastructure capable of storing, sharing, and analysing data [100].

Decision-making has become a key factor in global competition for all industries which has subsequently made the use of real-time analysis and large data processing (Big Data) capabilities a strategic issue for companies [101]. The strive for using data to make agile decisions has given rise to a need to leverage the full potential of the rapidly expanding data volume, velocity, and variety which has resulted in significant evolution of techniques and technologies for data storage, analysis, and visualization [100].

With the advent of the 4IR phenomenon, the volume of data has been expanding rapidly with many data types (structured, unstructured, semi-structured) and data sources available [60]. With the emergence of the 4IR technologies, companies have experienced rapid technological change [102], [103], exploding application and data [104], [105] agility in decision making [106], [107] frequent external shocks and growth in business management understanding of technology which result in data-based decision making.

According to [108]), with the 4IR technological innovations, the volume of data coming from sensors / internet sources has increased to the point that new data analysis techniques are required if organisations wish to integrate them in their business models to improve their performance.

It is posited by [109] that the company owns the data when it can fully control who can access the information and how it should be used. And [110], alert that in modern times, companies cannot afford to ignore information technologies.

It has been established that most critical systems and strategies rely on data, however, not enough investments have been made to ensure the reliability of data [111]. According to [112], in technological innovation management, data is critical for the following reasons: understanding of current and potential changes in the business environment, strategic and operational decisions are based on data and information, and data fosters strategic approach in organizations.

Other strategic issues brought about by the 4IR phenomenon include data security [113], [114], poor understanding of integration and systems architecture [115], and of some them have been identified as major barriers to the successful adoption and implementation of 4IR technological innovations. Other authors like [116], have identified data and information safety and security as one of the critical seven dimensions for implementation of 4IR technological innovations. That includes data storage, protection of data interfaces and use of services from ICT experts.

In the 4IR epoch, value chains within industries are interconnected and larger volumes of data are generated and the data is usually complex and heterogeneous. This increases the risk of data integrity and consistency [94], [117], [118], [119], [120].

According to [121] the functioning of the network and learning effects are heavily dependent on data. Network effects describe the value added by increasing the number of connections within and across networks, while learning effects are about capturing the value added by increasing the amount of data flowing through the same networks.

One of the critical sources of competitive advantage is speed-based strategies. Speed-based strategies are business strategies built around functional capabilities and activities that allow the organization to meet customer needs directly or indirectly more rapidly than its main competitors [95]. Data & information are key for speed –based competitive advantages as it result in optimal customer responsiveness, shorter product development cycles, reliable and speedy deliveries and distributions and most importantly quicker information sharing. According to [86], today's data & information technologies accelerate the speed at which enterprises make decisions, process information and collaborate to solve problems. It has been observed that 4IR technologies facilitate greater transparency and visibility throughout enterprise ecosystems [105].

The advent of 4IR technological innovations brought to the fore the essence of organizational agility [43], [111], [122], [123]. According to [124] time is at the core of technological innovations' success and timely executions, informed by timely data and information.

According to [125], the ability of organizations to analyse large sets of data using Big Data technologies / methodologies has become a critical basis of competition underpinning new waves of innovation. As noted by [126], data and information should be viewed by organizations as a new source of competitive advantage, and it has strategic implications for companies competing in the new age economy.

Studies by various authors [126], [127], [128], [129], indicate that data and information are new factors of production, in addition to the classical factors of production, which are land, labour and capital [130], [131].

A posited by [132], data has become a form of capital in the same way as financial capital due to its ability to generate new products and services. According to [133], data has become the underlying resource for business intelligence, and it has been the increasing availability of big data that has driven new forms of business model innovation.

As observed by [50], one of the drivers for adoption and implementation of the 4IR technological innovations is the inability to process large amount of data in the paper form, and the key success factors are compatibility, integration of information and communication systems and integration between multiple information model platforms.

Firstly, for the companies adopting and implementing 4IR technological innovation to achieve improved resource planning and improved information flow through their value chains [12], [21], [134] , they need to regard data and information resource management as a strategic issue. Secondly, process efficiencies and optimum productivities can only be achieved under shorter time delays [18], [20] and data and information is key for effecting it.

New and emerging technologies that are concomitant with 4IR technological innovations, trigger new needs and requirements for data and information, particularly processing of large amounts of data [23], [24] and pressure for data transparency [20]. The ability of companies to successfully respond to changes brought about by the emerging technologies concomitant with 4IR technological phenomenon, can only be achieved with the use of accurate and reliable data.

4 SUMMARY OF RESULTS AND DISCUSSION

4.1 Summary of Findings from Literature Review

Hereunder is a summary of the main findings from integrative literature review with respect to the research questions and objectives.

4.1.1 Data and Information Management in the 4IR Context

From the integrative literature review, many constructs pertaining to data and information management have been posited by various researchers and are summarized in Table 1. The main constructs include, data and information resource [57], [58], data interoperability [44], data and information transparency [76], data operational costs, data organising, data and information capabilities [66], [82], data and information privacy [77], [79], data and information usage [81], cyber-security [69], [73], efficient data and information management [68] , data collection [63], quantity of data and information [64], storage of data and information [61], connectivity [44], quality of data and information [88], data and information sources [58], accessibility of data and information [59].

The quality of data is important for predictive analysis. Predictive analysis is the application of skills, expertise, and algorithms on collected data to estimate the likelihood an event will take place in the future [89], [61], [90].

According to [91] with the increased connectivity and use of standard communications protocols concomitant with 4IR, the need to protect critical industrial systems and manufacturing lines and system data from cyber security threats increases dramatically.

It has been indicated by [93] that properties of data generated from 4IR technological innovations to be in large volumes, unstructured and in no direct relationship, generated and captured at a relatively high speed, and must be processed, structured and analysed within a shorter life cycle to create value.

Quality of data has at least four aspects, namely, competitiveness, accuracy, consistency and redundancy [94].

The above deliberations and discussion show that with advent of the 4IR phenomenon, the context of data and information management has changed significantly, having to encompass many parameters that were not critical in the preceding industrial revolutions. It is no longer simply about systems, context, retrieval and information environment, it now includes many additional aspects such as data transparency, interoperability, data privacy, cyber-security, reliability, high connectivity amongst others.

The 4IR epoch has made data and information management a vital component for companies adopting and implementing 4IR technological innovations. The context, scope, complexity and level of integration of data and information management have changed significantly from what it used to be. The integrated wireless network (IWN) in use needs to be aligned with 4IR data and information management to provide enough bandwidth for heavy communication and transfer of high volume of data.

Table 1: Data & Information in the 4IR technological innovation context

Data and Information Management in the Context of 4IR technological innovation	
Context Parameter	**Some Scholarly Publication**
Data and information as a resource	[57], [58]
Accessibility of data and information	[58], [59]
Data and information Sources	[58], [60]

4.1.2 Criticality of Data and Information Management for 4IR Adoption and Implementation

Table 2 is a summary of attributes for criticality of data and information management when companies are adopting and implementing Fourth Industrial Revolution technological innovations. Attributes of criticality include, amongst others, the need for data transparency, compatibility, integration and interoperability of data and information systems, prevalence of inter-organizational data and information exchange, intra-organization data and information dissemination, cyber-security threats etc.

New business models that have emerged with the 4IR technological innovations can only be optimized with the use of reliable data and information. As postulated by [53], [54], [152], [154], companies must develop business models that maximize innovation and effectiveness in leveraging 4IR digital technologies.

Shaping of future business strategies is key for the sustainable competitiveness of the companies [51], [149], [154], [155], which can only be achieved with effective data and information approaches.

The above discussion affirms the criticality of data and information management for the adoption and implementation of 4IR technological innovations for the companies. The 4IR phenomenon is a data-driven paradigm because data and information are at the core of digitization [37]. It exhibits that data and information, particularly in the 4IR epoch, is an important lever that companies use to create competitive advantage.

Table 2: Key Data / Information Attributes for Criticality of Data and Information Management for 4IR Adoption and Implementation

Key Data / Information Management Citicality Attributes for 4IR Adoption and Implementation	
4IR Attributes	**Some Applicable Publication**
Data transparency	[12], [20]
Compatibility, integration and interoperability of data / information systems	[21], [50]
Integration amongst information platforms	[13], [21], [22]
Stakeholder/ ecosystems approach data management	[135], [136], [137], [138]
Inter-organizational data and information exchange	[18], [19], [61], [139]
Intra-organizational data / information dissemination	[16], [50], [51], [108], [134], [140], [141]
Inter-disciplinary collaborations	[43], [52], [61], [142]
Cyber-security threats/ regulatory requirements	[143], [144], [145]
Processing of Big Data / large amaounts of data	[2], [12], [21], [22], [23], [24]
Emerging 4IR technologies	[17], [122], [146], [147], [148], [149], [150], [151]

The findings also underline the complexity of the technological environment, exacerbated by the advent of the 4IR epoch, within which companies has to operate. According to [156], the annotations of the data entities are very diverse and it is an increasing challenge to incorporate diverse data repositories with different semantics for advanced data analytics. Moreover, this new reality is a strategic issue for companies as it has direct impact on technological innovation and performance of the companies, as well as on their sustainable competitive advantage.

4.2 What is the proposed approach for data and information management for the Fourth Industrial Revolution technological innovations?

According to [8], two key reasons for poor data and information quality are the rush to install new systems and the failure to take up an integrated view of the organization's data and information requirements.

It has been proposed by [9] that some critical points for organizations to consider when dealing with data and information resources, are, focused internal data management programs, honed data needs, identification and management of the most critical information chains, recognition of the proper role of technology, development , maintenance and availability of the inventory of data resources, terms and conditions under which data may be accessed, clear delineation of management accountability for data, leadership for data management programs.

Figure 2 shows the data and information resources planning process as posited by [8]. It also shows how the Data and Information planning processing could be aligned with the business direction. This is one of the Data and Information Resource Management Planning models that were compiled prior to the ubiquity of the Fourth Industrial Revolution phenomenon.

According to Figure 2 , the process starts with assessment of the company's information usage, data and information architecture, strategic plan and operational plan. As shown in Figure 2, feedback is only happening between Assessment of Information Use and Management "and "Vision of How the Business Should Use Information". This might not be adequate when dealing with data and information concomitant with complex 4IR technological innovations.

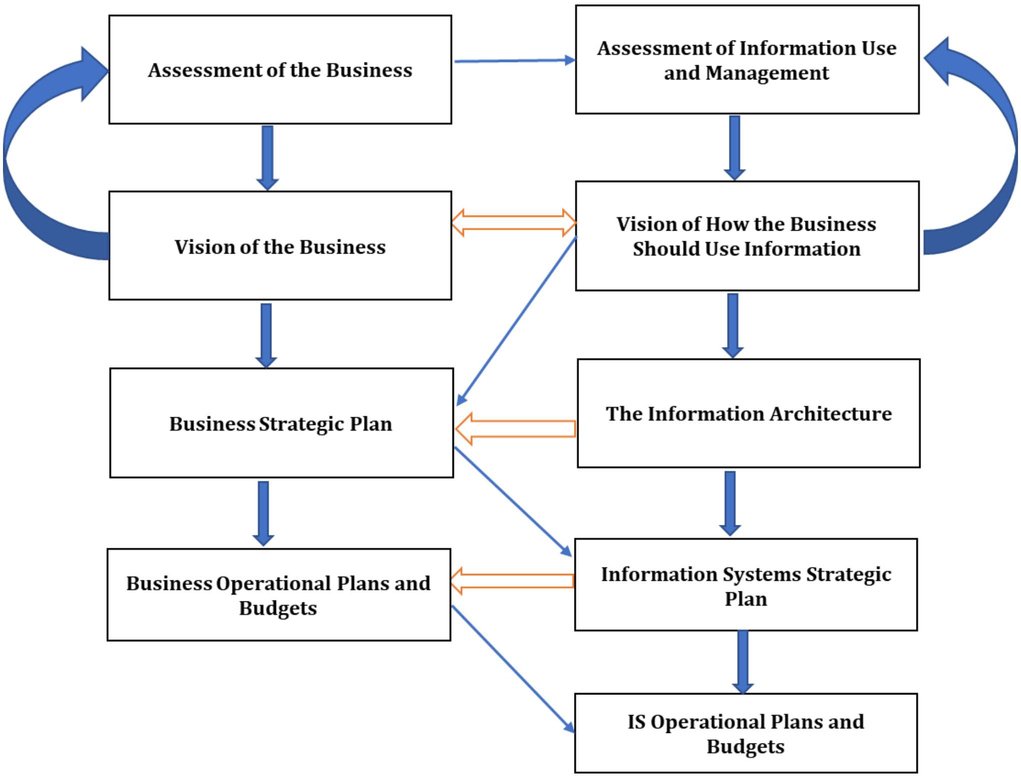

Figure 2: Information Resource Planning Process [8]

It has been reported by [157] that the emergence and diffusion of 4IR digital technologies have led to increased data and availability, which has subsequently increased the importance of data and information management. Considering the complexity , level integration and intelligence concomitant with Fourth Industrial Revolution technological innovations, Figure 2 needs to be complemented so that it incorporates the specific complexities associated with 4IR phenomenon, and Figure 3 does just that by proposing a complementary data and information planning model that can be used by companies when adopting and implementing 4IR technological innovations.

This proposed model encompasses the following key dimensions: fundamental complementary functions of general management functions (planning, organising, leading and control), PESTEL (drivers, enablers and constraints), Technology, and Innovation management process framework (identification, selection, acquisition, exploitation and protection), data & information planning process and performance characteristics & outputs.

When conducting data and information management and resource planning, it is important to understand the environment in which the organization operate, hence the need to have full appreciation of PESTEL constraints, enablers and constraints.

In contexts of data and information management for 4IR adoption and implementation, drivers and enablers can be seen as external or internal triggers for why organizations engage in data and information management.

The proposed model commences with the identification of 4IR data and information requirements. As posited by [158], identifying, and agreeing on the requirements for a new information technology (IT) application are two of the most difficult tasks in the information systems delivery (ISD) process.

This step is an integral part of the framework as it is about understanding data and information management's challenge that the company needs to attend to. It is in this step whereby a desired level of data and information management for 4IR technological innovation will be set. This step is particularly important as it has been established by many authors that large volume of data gathered through various technologies used in 4IR leads to difficulty in extracting the useful data [94], [117], [118], [119]. This step is meant to assist companies in generating data and information of value.

It has been alerted by [158] that not only are there multiple stakeholders whose various ways of understanding requirements must be taken into account and reconciled, but their ideas may change, particularly in long-term projects or if business conditions and key stakeholders change.

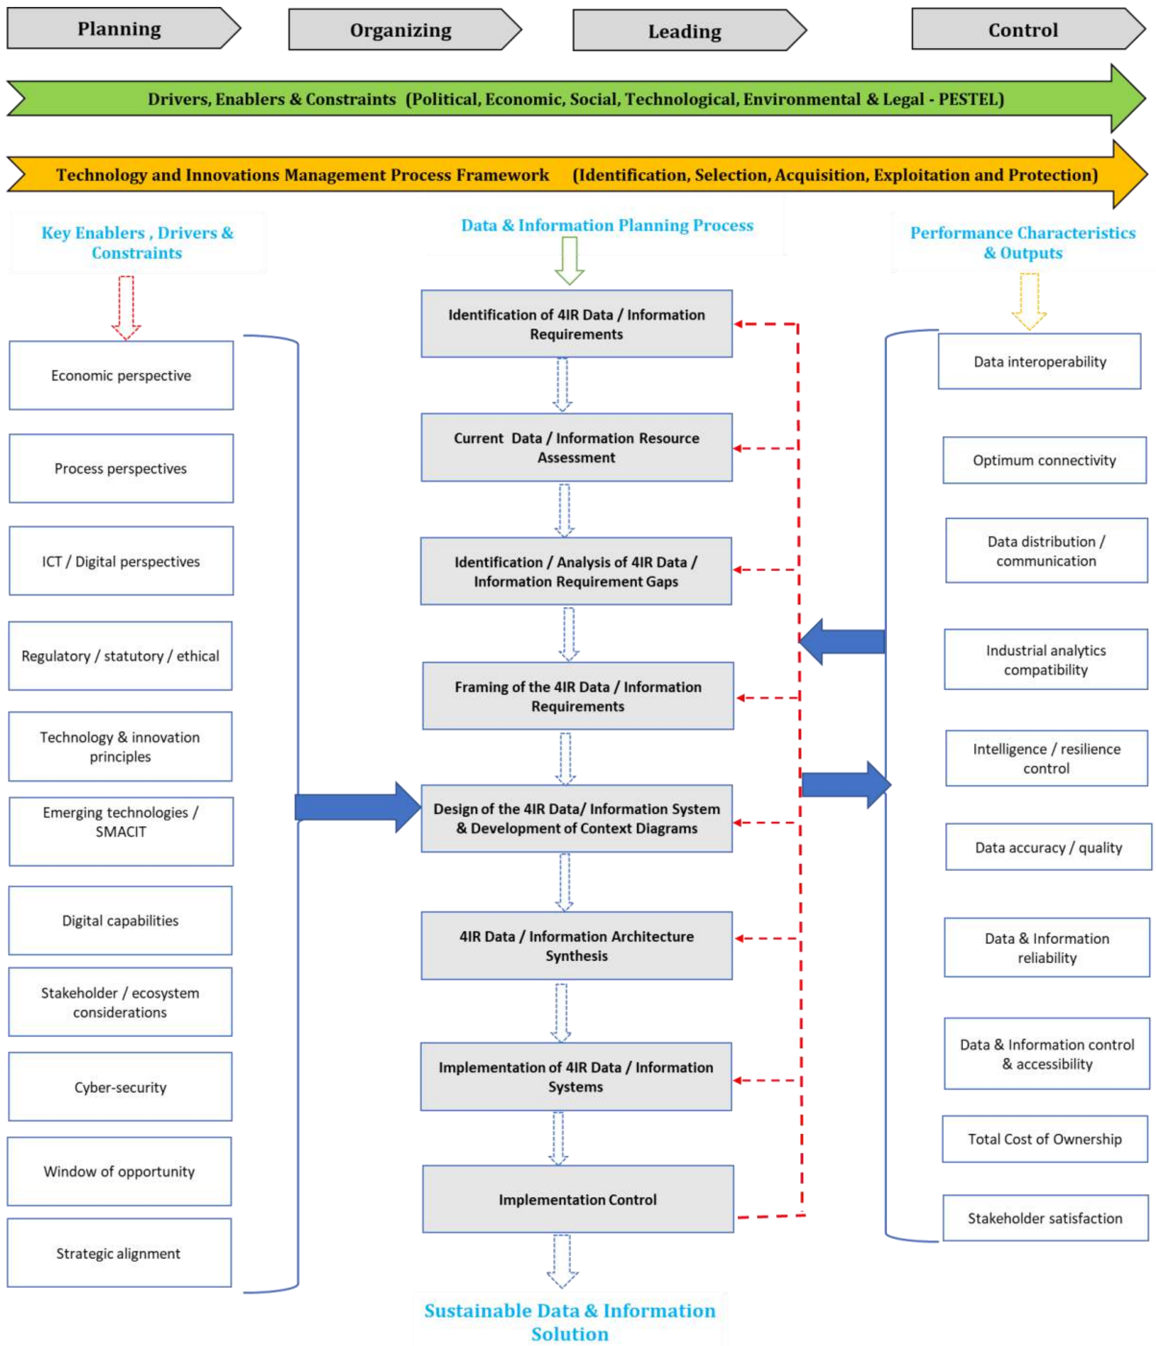

Figure 3: Proposed Data and Information Planning Model

The second step is to assess the current data and information resources status. This step is about determining the current status of data and information management which forms the basis for the gap analysis. It has been found that in some instances companies are not ready with all the technological infrastructure needed with every stakeholder in the value chain [35], [119], [159], thus creating a barrier for successful adoption and implementation of 4IR technological innovations.

The third step in the proposed model is about gap analysis of the 4IR data and information requirements and the current resources status. This step allows for analysis and prioritization of the gaps between the current and 4IR data and information requirements of each of the alignment components, and it is this step that provides the major content of the business. Understanding of the gaps will assist in ensuring that adequate focus is achieved, and effective prioritization is made.

The fourth step is the framing of the 4IR data and information requirements and is essentially about the important information applications and technologies. According to [160], the main objective of the framing process is to ensure that the right problem is tackled, from the right perspective, by the right people and it assist aligning the team towards success and reduce the probability of failure.

The fifth step in the proposed data and information planning process, is the design of the 4IR data and information system and development of context diagrams. [161] warns that infrastructures do not grow from scratch, but inherit the strengths and limitations from the existing base. According to [162] data and information infrastructure only creates value if it reflects a large and diverse user base and components, and most importantly data and information management system should be designed for direct usefulness. Emphasis has been made by [161] that design rules relate to a prioritization of immediate use value by being simple to implement and use, as well as to postpone scalability, extension, and completeness of the solution.

On completion of the design of the 4IR data and information system and development of context diagrams the next step is the synthesis of 4IR data and information architecture. The 4IR data and information architecture synthesis is about the data and information technology priorities, policies, and choices that allow applications, software, networks, hardware, and data management to be integrated into a cohesive platform. According to [8] data and information architecture specifies how the technology, human assets and the IS resources should be deployed to meet the companies' data and information needs and requirements. Elements of the architecture include, but not limited to, hardware, software, network, data, personnel, management etc.

Step number seven in the data and information planning process is about implementation. This step is the "doing" part of the proposed model where the organising and leading are critical to ensure that all that have been identified are implemented effectively and efficiently. It is at this step that alignment with respect to business and functions plans, leadership, culture and any necessary support systems must be ensured.

The last step in the data and information planning process is implementation control. According to [163] the controlling function involves monitoring the activity and measuring results against pre-established standards, analysing and correcting deviations as necessary and maintaining/ adapting the system.

In conclusion, the proposed model complements data and information resource planning models that were adequate for the industrial revolutions preceding 4IR. This proposed model will assist companies in honing their data and requirements as it gives some guidelines of how to approach data and information management and planning in the 4IR epoch. It will also help in alerting companies in understanding the importance of identification and management of most critical data and information chains that every company adopting and implementing 4IR technological innovations should take into account.

What is also unique about the proposed model is that it is not only about ICT / digital technologies, but it also renders full recognition to other complementary management disciplines such as general management, strategic management, and technology management. Thus, it is an inclusive data and information management framework and is integrative in its approach.

5 CONCLUSION AND RECOMMENDATIONS

This research paper highlights the criticality of data and information resources management and planning for adoption and implantation of 4IR technological innovations. It has brought into light that the pervasiveness of the 4IR technologies commands for new forms of data and information management and planning to effect and support 4IR technological innovations.

The motivation for this research stems from the lack of existing research focused specifically on data and information management and planning for industries adopting and implementing 4IR technological innovations. Data and information management approaches and strategies for industrial revolution preceding 4IR are not adequate as 4IR technologies brought with unprecedented complexity, levels of integration and co-ordination and unprecedented volumes of data & information.

As it would be the expectation with any technological innovation, it is critical to understand the mechanisms and processes through which data can be used to add business value to user companies, and to have a clear understanding of the concomitant elements and their interdependencies.

The study revealed that data and information in the context of 4IR technological innovation has a broader meaning and implications, which comprises data compatibility, integration and interoperability of ICT and systems, connectivity, cyber-security, data transparency amongst others. It also brought in the postulation that data and information management, particularly in the 4IR epoch, should be viewed to encompass data and information that the company utilizes as well as the broader spectrum of emerging, convergent and linked technological innovations concomitant with 4IR phenomenon.

This research paper proposes a framework with the following key action fields, fundamental complementary general management functions, PESTEL enablers, drivers and constraints, technology and innovation management process framework, data and information performance characteristics and outputs & data and information resource planning, that could assist with data and information approach when adopting and implementing 4IR technological innovations.

To ensure that data and information management systems are aligned to 4IR technological innovation, companies must engage in a pro-active, dynamic data and information resources planning as shown in the proposed model. The proposed model for data and information management for 4IR technological innovation is a critical base for inputs into the framework for adoption and implementation of the Fourth Industrial technologies.

Important to emphasize is that data and information management /resource planning model should be linked and aligned to the company's business plan and strategic goals.

This study contributes to the Fourth Industrial Revolution body of knowledge in twofold: firstly, it highlights and contextualize the criticality of data and information management and planning for adoption and implementation of 4IR technological innovations. Secondly, it proposes a framework that can be a useful input into business strategies, technology management frameworks and policy-making by scholars, practitioners and policy makers respectively. The study also enriches the body of knowledge in the field of technology management, general management and strategic management, ICT/ digital management by highlighting the complementary synergic possibilities.

Recommended future research work could include an in-depth case studies with quantitative and empirical approaches to offer an opportunity for the application and understanding of the proposed data and information management and planning framework.

ABSTRACT

The popularity of lean manufacturing mostly stems from empirical evidence that it enhances a company's competitiveness and quality by reducing all forms of waste. The South African automotive manufacturing sector is in a state of despair with losses from Covid 19 and the April floods of 2022. When demand is high, lean and the Toyota Production System (TPS) methodologies are ignored and only volume is prioritized, which contributes to defects, scrap, and failure to meet operation targets and increase in vehicle recalls. The purpose of this study is to assess lean manufacturing practices (LMPs) and the extent to which the organisation utilizes innovative strategies to improve sustainability in a highly competitive manufacturing environment. The research methodology is mixed method in nature using qualitative and quantitative instruments for data collection.

Keywords: Lean, Quality, Sustainability

* Corresponding Author

1 INTRODUCTION AND BACKGROUND

"*South Africa's weak manufacturing growth has hurt growth in sub-Saharan Africa*" [1]. South Africans are concerned about de-industrialization over the past 20 years and that imported goods are increasingly replacing locally produced goods. As a result, South Africa's manufacturing future is being questioned and challenged. This is occurring against a backdrop of relentless government intervention aimed at stabalising the tide of de-industrialization while positioning the manufacturing sector in a more favorable and expansive position [2]. Manufacturing is the lifeblood of any country's economic growth and critical for job creation.

Between 2014 and the first quarter of 2020, the sector's contribution to GDP was less than 1 percent. Between the second and third quarters of 2020, the sector recovered and recorded a contribution of 10.8% and 16.2%, respectively. Aspects such as the easing of closure restrictions, improved production of food, beverages and motor vehicles contributed to this higher contribution. Be that as it may, the sector's activity level remains worrisome and is significantly below that of recent years. For example, annual manufacturing output at the end of the fourth quarter of 2020 was down by about 11%, due to declining steel demand and Covid-19-related production stoppages [3].

Currently, the main challenges in the this sector are the quality of the product that does not meet the global standard, defective products that affect the image of the organization, recalls, and the lead time, where customers do not receive their orders on time, which contributes more to customers opting to utilize alternatives. Given the fact that Toyota is highly rated in the utilization of lean, the study's purpose is to examine lean manufacturing practices (LMP) and the extent to which the automotive sector uses innovative strategies to enhance quality and its sustainability [4].

The automotive sector has introduced smart tools that can detect anomalies in use and stop the production line until the problem is fixed; by introducing the smart tools, the company is able to improve quality. Every product or service is judged by its quality, and the quality of the product improves the demand. TSAM invests more in quality through training and the latest facilities. Motorized sector has also introduced the Manufacturing Academy, whose main purpose is to recruit unskilled workers directly from high schools and train current employees in the sector's principles and tradition.

Currently in the automotive sector, when the demand is high, lean and Toyota Production System (TPS) methodologies are ignored and only volume is prioritized, which contributes to defect flow out of the process, a scrap rate that is too high, failure to meet operation ratio (OPR) and straight delivery rate (SDR) targets, and in some cases, recalls. Downtime on the production line, delay of parts, members not achieving target time, machine breakdown, and no feed from the lines behind are the factors that affect the daily target, resulting in a delay in the entire production line.

1 LITERATURE REVIEW

1.1 Introduction

To identify appropriate strategies that could be employed to meet the study's objectives; this section evaluates the literature on previous research projects based on lean manufacturing methods and quality measures. The section examines two topics: lean theory and quality measures.

1.2 Lean Theory

The studies find that despite numerous studies providing empirical evidence that lean improves quality and eliminates waste in the value chain, implementation of the benefits, application, and opportunities of lean manufacturing practice (LMP) is still slow, warranting further evaluation. Less than 30 percent of LMPs are successfully implemented. In addition, researchers have documented numerous cases of failed AMP implementations, even in companies in developed countries such as the U.S. and the U.K [5]. The literature focuses primarily on the benefits of implementing lean manufacturing principles in an organization, but researchers have acknowledged the amount of work required to critically evaluating a successful lean manufacturing program, and they note that little research addresses the challenges of sustaining lean manufacturing once it has been implemented in a production system [6]. Although many companies report great benefits from lean applications, there is still much uncertainty about the applicability of lean outside of the stable, high-volume manufacturing environment [7].

Many researchers have proven that lean can shorten lead time, improve quality and productivity, reduce inventory, and lower costs, while on the other hand, profit and competition increase. However, not all lean initiatives are successful; some fail due to inadequate plans to implement lean strategies. Lack of management support, lack of training, and unwillingness of employees to change are all factors that contribute to the failure of lean. It is impossible to manage lean without evaluating its results. By implementing a quantitative method to determine lean performance, decision makers can quickly review the efficiency of manufacturing processes and identify potential areas for improvement [8]. Lean principles can occasionally fail because business leaders often do not have a map of their own company [9]. Increasing globalization and rising customer demand are increasingly forcing manufacturing companies to seek effective and flexible means to overcome challenges in applying lean. Many academics have already contributed knowledge about lean manufacturing, but they have yet to distinguish the exact way in which lean tools are applied, making it difficult for scholars to grasp the practicality of lean. Companies, especially in the automotive industry, are finding it difficult to compete in the global marketplace. Therefore, they are turning to alternative tools and strategies to succeed, such as lean manufacturing, which aims to meet customer demand while reducing waste [10].

The success of manufacturing companies is generally determined by their ability to carry out daily operations using effective work methods and techniques. Several basic principles for production management in a company are part of lean manufacturing. Numerous companies have recognized the need to put lean principles into practice to increase productivity and gain a competitive advantage in the very turbulent global business environment. To gain insight into the elements that influence the sustainability of lean manufacturing, the factors that influence lean manufacturing principles in a production system were examined. A checklist is used to give some order to the observations on the different topics. Without neglecting the other topics of the study, the study concludes that operations meetings, training, and problem solving are the three most important topics that require attention from all the observed topics with different observable elements. If the way training is conducted is improved, many other problems could be solved as training has been found to be the main cause of other problems as shown in the study [11]. To understand the challenges and barriers of lean, we need to examine current technical management, leadership culture, organizational science, and employee development [12]. Lean practitioners have identified seven forms of waste: Transportation, Inventory, Movement, Waiting, Over processing, Overproduction, and Defects, which need to be clearly understood and well communicated in production [13]. The seven forms of waste are listed as follows [14]:

1.3 Defects

Customers place a high value on quality, and it is this factor that keeps any business afloat. Defects can be found not only in the manufacturing process but also in any other process, such as the maintenance process. For example, if a maintenance repair is performed and the fault returns quickly, this indicates a flaw in the repair process. Standardization of work procedures is an effective way to reduce the likelihood of failure and improve quality. Processes can be mapped, and potential quality issues can be displayed on charts. If a quality issue arises, the standard procedure should be reviewed and updated to avoid making the same mistake in the future [15].

1.4 Unnecessary inventory

Inventory is a type of waste that should be minimized. Lean inventory management is considered worthwhile inventory management. The following activities should be done to attain a lean inventory system [16]:

1. Production levelling is the lean strategy employed to remove overproduction and consequently decrease the inventory level.
2. Adoption of JIT and Kanban is an important activity to achieve lean inventory.
3. Total productive maintenance (TPM), statistical process controls (SPC), and total quality management (TQM) guarantees the accessibility of machines and aid managers in implementing inventory plans.

According to empirical research, lean production does, in fact, boost a company's competitiveness. Increased inventory waste will result in higher interest, space, record-keeping, and obsolescence expenses. [8].

1.5 Waiting

A backlog of materials is a waste. An operator who has no meaningful task to accomplish while waiting for supplies or instructions is wasting time.

1.6 Transportation

Materials must be transported further and at greater expense due to an unsatisfactory industrial layout. To shorten the moving distance, work canters should be close to one another. Someone might argue that WIP inventories have no room in close work canters. The material should be transported to the location where it will be used. The material must be carried directly from the vendor to the assembly line area where it will be used. The term for this technique is point-of-use storage (POUS) [17].

1.7 Inappropriate processing

Over-processing is unintentionally doing more processing work than the customer requires in terms of product quality or features, such as polishing or applying finishing in some areas of the product that will not be seen by the customer. Over-processing occurs in situations where overly complex solutions are found to be simple procedures [18].

1.8 Overproduction

Overproduction results in more material handling, poor quality, and irrational inventories. Consuming resources for things that aren't necessary could result in a lack of resources for products that are. Never overproduce goods just to keep workers and equipment occupied. Leave it alone if the needed load is less than the capacity. Labour can be transferred to other departments, used for machine cleaning or maintenance, accepted for training and education, etc.

1.9 Unnecessary motions

To avoid running and handling losses, the operator must have his tools handy and must be handed the required parts or materials in the correct orientation. The operator should never leave his workstation to look for spare parts or tools. 5S is a good technique to eliminate the problem of looking for tools. Access to tools is greatly improved by keeping them organized and placed in a visible location [15]. Takshi Osada invented 5S in the 1980s as a management tool or approach to create and maintain higher quality, productivity, and a safe work environment in an organization. 5S not only streamlines the work environment and reduces waste, but also helps improve workplace safety [19]. The main problem is that management often lacks an organizational chart, which occasionally causes lean concepts to fail. Recent research shows that only 55 percent of middle managers can accurately identify even one of their company's top five strategic priorities, and more than half of them fail when it comes to explaining strategy to their employees. Not only are strategic goals poorly understood, but they also seem disconnected from the company's larger business plan [20].

2 QUALITY MEASURES

The cost of quality is more than twice the cost of error-free execution. All resources and costs spent to produce the defective product are lost and spent again to compensate for that defect [5]. Quality principles use simple and clear methods that must be followed if the company wants to achieve world-class quality [21]. The company should understand that these methods will not work without a strong corporate culture. Training, technology, management support, poor planning, and employee attitude are some of the many factors that affect the quality of the product produced by a company [22].

Quality is considered one of the most difficult problems that manufacturers must solve in the era of globalization as they seek low-cost distribution channels for their goods. Companies need to maintain quality at marginal cost and apply total quality concepts as the best approach to solve this problem. One possible cause of the recalls was Toyota's inability to keep pace with its recent aggressive growth. A requirement that leads the company to ignore Lean or TPS methodology and focus on chasing demand. This study has provided a systematic framework of Crosby's 14 quality principles for manufacturing challenges and contributes to the body of knowledge by recognizing a hierarchy model of variables used in an ISM-MICMAC strategy for successful TQM implementation. Up to 85 percent of all inefficiencies are the result of a company's systems [23]. The TQM methodology extends the traditional manufacturing process to the entire organization and all of its functional areas. According to the findings, the stated principles of "take action to effect change," "introduce training," "encourage employees to learn," and "introduce leadership" are strategic requirements, while "reduce fear," "break down barriers between personnel areas," and "eliminate number quotas" are tactical requirements. Operational requirements for TQM applications include adopting the new philosophy, creating consistency in improving products and services, and ending reliance on mass audits. TQM is a set of management principles for continuously improving product quality and operational efficiency to satisfy customers. It is now widely used in the management jargon of companies on a global scale [21]. TQM is the main manufacturing strategy that plays an important role in strengthening the competitiveness of companies in the market, and the popularity of lean manufacturing is largely due to empirical evidence that it increases a company's competitiveness [8].

The TQM principle is illustrated in the figure below:

2.1 Total Quality Management

The theory of total quality management (TQM) places a strong emphasis on employee engagement, customer happiness, and continual development. The overall goal of an organization is to meet the expectations of the client or customer. For every organization or firm to be resilient and competitive, the business world has prioritized quality [24].

The figure below (Figure 3.1) illustrates the concept of TQM.

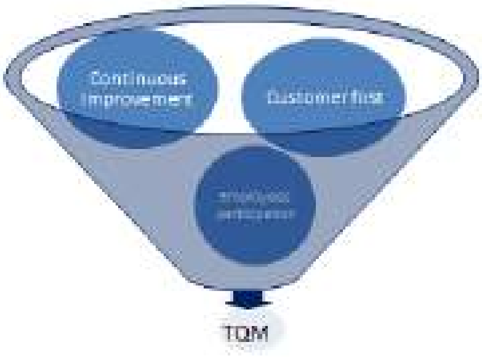

Figure 3.1: Total quality management

The figure above (Figure 3.1) is showing TQM concept. To achieve TQM the customer comes first and to meet the needs of the customers there must be employee participation in the continuous improvements.

The study goes on to state that several studies have been conducted on TQM, but no study has examined the relationships among Deming's 14 quality principles. The study concludes, "*Top management should promote employee education and institute leadership to successfully implement TQM in service and manufacturing companies*". TQM is a philosophy that emphasizes customer satisfaction, employee involvement, and continuous improvement [25].

The seven quality control (7QC) tools can be of great help in improving quality in a company. Control sheets, Pareto charts, cause-effect diagrams, flow charts, histograms, scatter diagrams, and control charts are examples of graphs for improving product quality and competitiveness. Companies' main goals are to improve quality and reduce costs and lead times. They achieve this by putting the ideas of lean manufacturing and quality measures into practice [26].

The quality of goods and services is largely determined by the competence of the people who provide them. In commerce, products are tangible items that are exchanged for other goods or services [27]. Services, on the other hand, are activities provided by others, such as teachers, doctors, hairdressers, dentists, and even Internet services. According to economic theory, the end consumer is rewarded with satisfaction and utility through the consumption of products and services. Businesses consume products and services as part of the process of producing other goods and services. Marketing theory, on the other hand, uses the goods-services model [28]. Employees' work experience has a significant impact on how customers perceive the quality of goods and services. Consumer satisfaction is determined by receiving the goods and services that the customer expects. If an organization's employees promise a good or service that the operation cannot deliver, the customer's expectations are not met, the consumer is disappointed, and the quality of goods and services is not perceived. Operations and production do not determine the quality of goods and services. Customer expectations, the actual goods or services received, and the manner in which the service is delivered [29].

The ability to achieve higher productivity standards without compromising quality is an important goal of a manufacturing company [19]. Quality has a cost that is more than double the cost of doing things well the first time. All the resources and expenses used to produce the defective product have been lost, and new expenses are incurred to make up for that defect. In addition, there are other costs associated with implementing changes, root cause analysis, and process improvement. Defects, rework, and additional requirements or adjustments are added together to form the cost of quality. Some examples of lean manufacturing techniques include cellular manufacturing, multifunctional workforces, lot size reduction, just-in-time (JIT), labour delegation, TPM, setup time reduction, TQM, continuous flow manufacturing, agile manufacturing strategies, safety improvement programs, process capability measurements, and human resource management (HRM)[16].

The fierce competition that exists today on a global scale in all industries is forcing companies everywhere to constantly strive to improve their goods, services, and operations. Toyota Motor Corporation is one of several companies in the automotive sector that have distinguished themselves by placing quality at the heart of their production process. The Toyota Production System, which promoted the formation of business excellence models, has been continuously developed, applied and refined to improve their goods, services and operations [30]. The factors that affect product quality in Kenyan printers are training, technology, management support, poor planning and employee attitude. These are just some of the many factors that affect the quality of the product produced by a company [31]. Motor sector defines quality as a product that meets and exceeds customer expectations. To ensure good quality at motor sector, the company has implemented various quality measures, such as quality cycles, kaizen, cause-and-effect diagrams, problem-solving procedures, Group-by-Off (GBO), Poka-Yoke systems, suggestion system, the 5Tei system, system check sheet, Andon system, My Problem and Countermeasure Sheet, system check sheet, defect tracking sheet, and the use of smart tools TSAM includes Hoshin Kanri (policy management) and Nichijo Kanri (daily management) by management and supervisors [32].

2.2 Cause-and-effect analysis

The cause-and-effect diagram (Figure 3.2) illustrates the problem-solving technique that motorized sector employs to get to the root cause of the problem. The diagram shows one of the functional a defects that was picked up at group-by-off (GBO).

In this diagram (Figure 3.2), it is easy to pick up what was the cause of this defect (pinch bolt loss). The first noticeable thing is that under "*machine*", the poka-yoke tool was faulty. A poka-yoke is a tool that detects if there is a problem and stops the line, but in this instance, it did not detect the problem. It is also noticeable under "*material*" that the scanner was not working and the bolt was cross-threaded, which caused the bolt to not be fully tightened. The bolt was not pre-fitted, which caused the cross threads. Under "*man*," it shows that the operator did report that he was experiencing a problem with the poka-yoke tool. The finding from the analysis shows that the problem occurred under "*method*", "*machine*" and "*material*", which led to "*pinch bolt loss*". After the root cause has been found, a countermeasure needs to be implemented to ensure this defect does not flow out again.

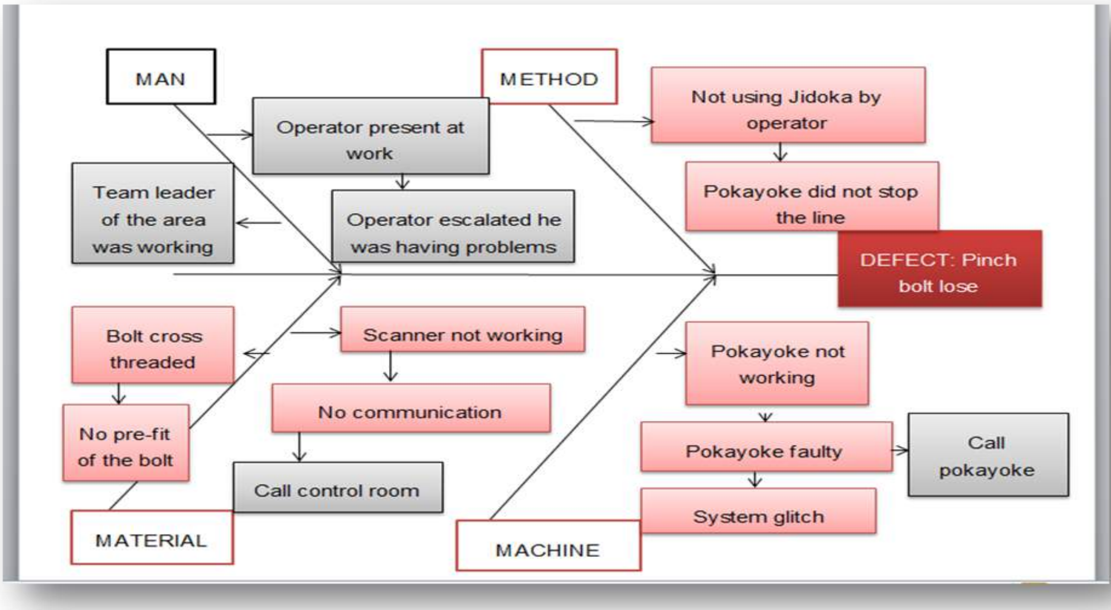

Figure 3.2: Cause-and-effect analysis

2.3 Group-by-Off (GBO)

The GBO diagram below (Figure 3.3) illustrates the system that the automotive sector employs to pick up the defects that occurred during the process.

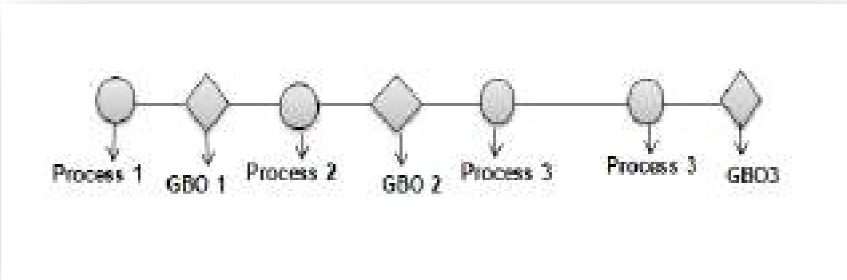

Figure 3.3: Group-by-Off

Each production line has a quality gate, also known as a group-by-off (GBO), where double quality assurance checks are performed. The sector has established a culture in which the customer is a part of the production line; process number one sells the product to process number two, and so on until the product reaches a consumer who has paid for it, all while adhering to quality standards. The quality management system and standardized work are considered the organization's culture, which is followed by all of TSAM's affiliates.

3 RESEARCH METHODOLOGY

This section presents and justifies the methodology adopted for this study, and the approaches that were used to collect database on the research questions formulated. It also includes data collection methods and instruments, instrument construction (questionnaire), survey questionnaire development, and scale construction.

3.1 Research design

The mixed method design was used to examine and analyse data. The importance of mixed method research is that it provides the time, place, and tools for the researcher to describe, analyse, interpret, and clarify experience as it is lived and constituted in awareness. It aids researchers in comprehending the views, intricacies, and under-researched areas of participants. Because the study's focus was on examining lean manufacturing techniques and strategic sustainability in manufacturing sector to enhance quality, competitiveness and sustainability, it was based on an exploratory research paradigm to allow a complete review of the causes of not attaining the aforementioned targets [33]. To find fresh insights into phenomena, exploratory investigations often take an open, flexible, and inductive approach to study. Forty-four (44) questionnaires were sent out to various respondents in the organisation. Of the fifty (50) that were send out only 35 of them were returned representing a response rate of 80%.

3.2 Target population

In this study, the target population was fifty (50) top management staff in four departments at TSAM. The study focused only on TSAM, and survey questionnaires were distributed via email among the sample group.

3.3 Sampling method

The probability sampling method was employed by the researcher, where individual components are selected through a logical, technical, or mechanical process, similar to the lottery approach, rather than being consciously or thoughtfully chosen from a set of components [33].

3.4 Measuring instrument

For the proposed research, a survey questionnaire was constructed that is in line with the identified objectives of this study. Relevant questions in the data collection instrument were also constructed uniquely and originally.

3.5 Data analysis

Statistics Package for Social Scientists (SPSS) is the best application for evaluating data. For this reason, the researcher divided the qualitative data analysis process into five stages and used SPSS version 27 for the quantitative data. To create graphs, tables, and correlations for descriptive analysis, SPSS version 27 was specially employed.

4 RESULTS AND DISCUSSION

4.1 Factors that affect the quality

The figure below (Figure 4.1) shows the factors that affect quality in motor sector. This figure also indicates where the company must focus on improving in order to achieve high quality.

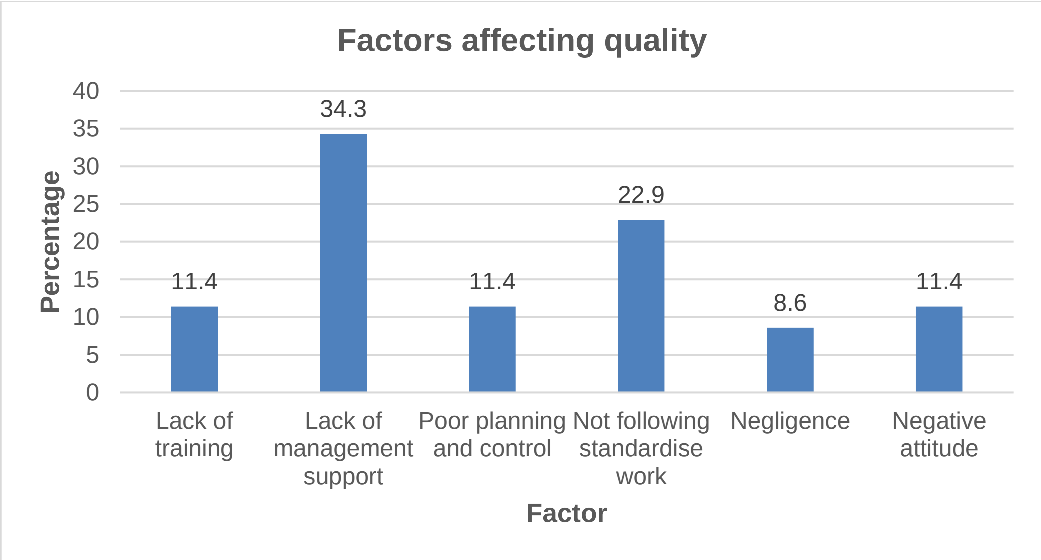

Figure 4.1: Factors affecting quality

Management support refers to managers' willingness to adapt to employees' schedules and tasks and provide support that can help employees better manage and complete their tasks. This is confirmed by the results of the study, which show that about 34.3 percent of TSAM employees believe that lack of management support is the biggest factor affecting the quality of work. However, not all lean initiatives are successful; some fail due to inadequate plans to implement lean strategies. Lack of management support, lack of training, and unwillingness of employees to change are all factors that contribute to the failure of lean, which also leads to poor product quality. Customers place a high value on quality and that this factor keeps any company afloat. Defects can occur not only in the manufacturing process but also in any other process such as maintenance process. For example, if a repair is made and the defect quickly reappears, this indicates a defect in the repair process. Standardizing workflows is an effective way to reduce the likelihood of errors and improve quality [15].

4.2 Quality measures

The figure below (Figure 4.2) represents the quality measures that are in place in TSAM and also shows which quality measure is the most effective.

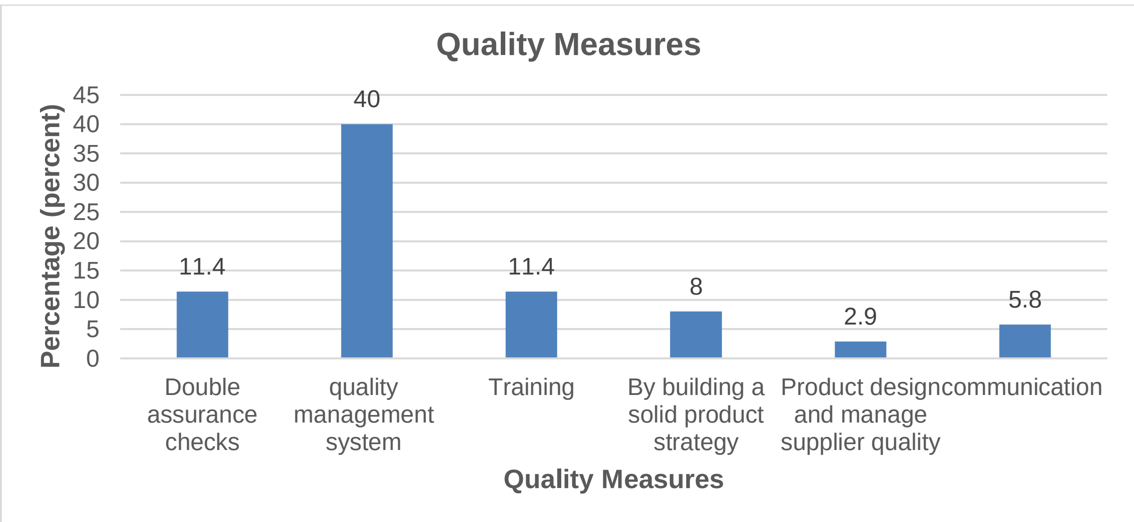

Figure 4.2: Quality measures

The main challenges in the motor sector are product quality that is not up to global standards, defective products that affect the image of the company, and lead times where customers do not receive their orders on time, which contributes to customers being more likely to use alternatives. This assertion is also supported by the results of this study, which show that 40 percent of the respondents believe that the company has implemented some quality management systems [4]. This is also supported by the study that defines quality as only suitable for the intended purpose. The study further reveals that quality in the manufacturing sector is determined by how closely the product meets the specified product requirements. This ultimately leads to improved organizational productivity, which translates to a better work environment for employees and leads to business expansion. This ultimately leads to improved organizational productivity, which impacts a better work environment for employees and leads to the expansion of the company. Seven quality control (QC) tools are very helpful in improving quality within an organization to achieve higher quality. Inspection sheets, Pareto charts, cause and effect diagrams, flow charts, histograms, scatter plots, and control charts are the seven basic QC tools. To increase profit, quality is a critical aspect in the manufacturing industry [26].

4.3 Perception of lean

The perception of lean as understood by motor sector is depicted in figure 4.3 below.

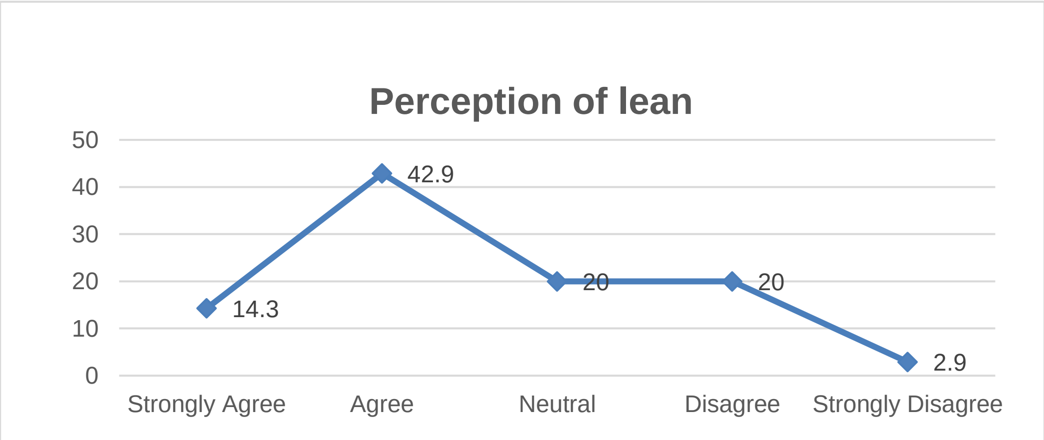

Figure 4.3: Perception of lean

The results show that about 42.9 percent of the respondents agreed that they had a better understanding or perception of lean. The respondents in this study were employees, department managers, senior executives, and directors who indicated they had a better understanding or perception of Lean. However, the main problem is that management often lacks an organizational chart, which causes lean concepts to occasionally fail. Recent research shows that only 55 percent of middle managers can accurately identify even one of their company's top five strategic priorities, and more than half of them fail when it comes to explaining strategy to their employees. Not only are strategic goals poorly understood, but they also seem disconnected from the company's larger business plan. The sobering reality is that most business leaders are unable to articulate their company's strategy in a simple and compelling way [20].

4.4 Good lean practices (continue practicing)

The figure below (Figure 4.4) represents the elements that motor sector must continue to practice.

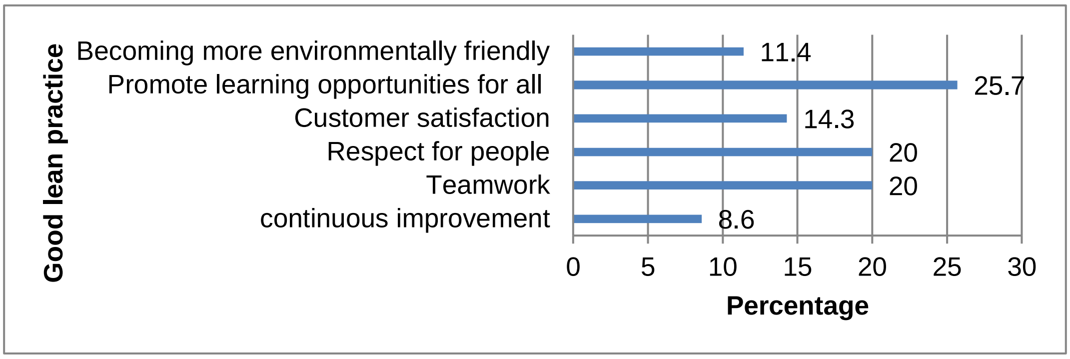

Figure 4.4: Good lean practices (continue practicing)

During the study, respondents were asked about the good practices they would like to see the organization continue practicing. About 25.7 percent recommended that the organization carry on promoting learning for everyone. About 20 percent of the respondents encouraged the organization to carry on promoting teamwork amongst employees, while the other 20 percent emphasized the aspect of respect for employees no matter their position in the organization. About 14.3 percent indicated that the organization should keep focusing on customer satisfaction; on the other hand, 11.4 percent indicated that the organization should become more environmentally friendly. The remaining 8.6 percent emphasized that the organization should continue focusing on continuous improvement.

4.5 Not good practices (stop practicing)

Figure 4.5: Stop practicing

The researcher asked the employees in motor sector about the practices that the organization should stop practicing, and the results indicated that 22.9 percent of the respondents highlighted that the organization should stop treating employees as numbers but rather as assets. Furthermore, 20 percent of the employees indicated that the organization should stop compromising on the quality of products over volume, while 14.3 percent said that the organization should stop prioritizing profit over employee well-being. About 11.4 percent of the employees emphasized that the organization must stop hiring or employing unskilled people in positions of influence. The other 11.4 percent said that the organization should stop setting unrealistic goals and practicing poor planning and control. The remaining 8.6 percent said that the organization should stop micro-managing employees.

The majority of employees believe that training and management support can improve quality. It was interesting to see that the majority of the respondents indicated that the level of communication was very good in the automotive sector; however, there was still room for improvement in downward communication.

There were some good practices that the respondents would like to see the organization continue practicing, such as promoting learning opportunities for all, continuous improvement, respect for people, teamwork, customer satisfaction, and becoming more environmentally friendly.

5 RECOMMENDATIONS AND CONCLUSION

5.1 Introduction

This section concludes the study by summarizing the key findings in relation to the research objectives

Objective 1:

What limitations, challenges and good practices of lean that can be identified in the automotive sector?

From the data in this study, it appears that the organization should stop treating employees as numbers, but rather as assets, and that the organization should stop compromising on the quality of products versus quantity. In addition, organizations should stop hiring or employing unskilled employees in positions of influence. This is consistent with literature highlighting that Lean and TPS methods are not prioritized when demand is high, which contributes to defects flowing out of the process, which later leads to a high scrap rate, excess parts from inventory, failure to timelines, or even recalls because the standard is not met. The daily target is always affected by downtime caused by stoppages on the production line, machine breakdowns, parts shortages, and lack of replenishment from downstream lines, resulting in a delay on the line [32].

5.2 Objective 2:

What are the quality measures that the automotive sector has implemented to improve product quality and competitiveness?

From the survey data, 40 percent of respondents indicated that quality management systems should be used in practice to ensure good quality. Literature indicates that the automotive manufacturing industry is the most important industrial sector in South Africa. The major challenges in the manufacturing sector are product quality that is not up to global standards, defective products that affect the image of the company, and lead times where customers do not receive their orders on time, which contributes to customers being more likely to use alternatives. This assertion is also supported by the results of this study, where 40 percent of respondents believe that the company has implemented some quality management systems to improve quality and competitiveness [4]

5.3 Objective 3:

What can the automotive sector recommend as best lean/TPS practices and strategic sustainability in other small and large manufacturing sector?

Various data collected suggest that the organization should stop setting unrealistic goals and poor planning and control, promote learning for all, invest in training and development, and improve communication. This is supported by the literature that suggests that training, technology, management support, poor planning, and employee attitudes are some of the many factors that affect the quality of the product produced by an organization [22].

6 CONCLUSION BASED ON THE STUDY

The main objective of this research paper was to assess lean manufacturing practices and the extent to which the automotive sector uses state-of-the-art facilities to improve quality and sustainability. Based on the results of the study, the following conclusions were drawn:

- In terms of lean implementation, the study concludes that the most important aspect of the organization is training. This is supported by the results of the study, with (50.8 percent) of respondents indicating that training is the most important aspect of the organization.
- The study concludes that the factors that impact quality are lack of management support and failure to follow standardized work procedures. The study also suggests that a negative attitude is the cause of many problems in the company and in the outside world. The responses show that (34.3 percent) believe that lack of management support is the main factor affecting quality, while (22.9 percent) believe that standardized work is the main factor.
- Regarding the perception of lean in terms of understanding, the study concludes that there is an understanding of lean production, as respondents can understand the issues related to the process of lean production. About (42.9 percent) of the respondents support the study's findings.
- In terms of perceptions of lean as it relates to lean practices, the study concludes that companies need to build a culture that emphasizes quality improvement and ensures that employees are satisfied with their work environment. The study also concludes that managers should increase job satisfaction and encourage personal development. Respondents (14 percent) support the study's findings.
- According to the research findings, the study can conclude that the vast majority (82.9 percent) of respondents want to satisfy customers, which indicates that respondents are willing to go the extra mile to satisfy customers.
- Based on the research findings on quality measures, the study concludes that quality management systems should be used in practice to achieve good quality. (40 percent) of respondents believe this is the best quality measure that can be implemented.

ABSTRACT

This study investigates how Systems Thinking can help organisation function better through proven Systems Thinking philosophies. The research is built around the current mode of thinking (traditional linear thinking) by means of assessing the organisational complexities, linear thinking philosophy, organisational policies, and the contributors to innovation challenges. The study was carried out using mixed methods, first the quantitative and thereafter qualitative method. Managers from different divisions and departments responded through the anonymous questionnaires and ten managers were sampled for in-depth follow-up interviews. The results showed that there are complex challenges that are experienced in the everyday business within the organisation due to a lack of Systems Thinking within the corporate. These challenges range from hindrances to achieving departmental goals which ultimately lead to not realising the main goal of the organisation, challenges with the written policies, synchronisation amongst different teams, etc. The study showed that linear thinking within an organisation hinders the organisation's chances of remaining competitive in the external environment (market).

Keywords: Systems Thinking, Corporate Entrepreneurship, Linear Thinking, Systems Thinking Tools, Competitive Advantage.

1 INTRODUCTION

Systems thinking focuses on addressing complex systems and diverges from conventional linear thinking that isolates observations of phenomena [1]. Numerous corporations face challenges and find it difficult to thrive in highly competitive environments. One of the factors contributing to these struggles is the prevalent perception of entrepreneurship as a linear process, rather than recognising it as a complex system with interconnected stakeholders and activities influenced by feedback loops. To unlock the full potential of businesses and corporations, establish a sustainable advantage, address the needs of the natural ecosystem, and maximise profits, it is essential to comprehend the application of systems thinking in corporate entrepreneurship [1].

Corporate Entrepreneurship is a term used to describe entrepreneurial behaviour within mid-sized and large organisations. Systems Thinking offers a framework for identifying and addressing future challenges by proactively developing solutions. It allows for the possibility of adapting or completely abandoning a concept based on the insights gained from a systems perspective or systems foresight, indicating whether the concept would be advantageous or not.

Businesses are dominated by feedback loops, coincidental consequences of business decisions concomitant structures, mental models, and wavering of inventory and staff levels, all these are all suited to systems thinking tools and concepts [2], [3]. Systems Thinking offers a meniscus for instituting and examining purpose, structure, and conduct in the context of a largely complex and dynamic environment [4], [5], [6].

In this study, Systems Thinking is employed effectively in the context of a local organisation by using the deductive method to understand how the traditional linear thinking philosophy is detrimental to business. Linear thinking can be defined as static in nature focusing on particular events, viewing behaviour generated by a system as driven by external forces and viewing causality as one-way with each cause independent of all other causes [18]. Taking into consideration the latter definition, the study's objectives were derived:

1. The challenges experienced with lack of Systems Thinking within the organisation,
2. Systems Thinking practices and its effectiveness in remaining competitive and relevant in the external environment, and
3. challenges that are faced within the organisation during the process of innovation.

The article commences by introducing the theoretical foundation and the conceptual model, which addresses the three research questions of the study. This is then followed by an explanation of the research design and methodology. The paper concludes with a discussion of the study's main findings and their implications within the organisation and lastly, the research limitations are provided.

2 THEORETICAL BACKGROUND

Meadows [7] stated that despite the technical brilliance that has been meant to diminish the various challenges that face society, such as poverty, environmental degradation, unemployment, and drug addiction, these issues continue to exist. The concept of systems thinking is a framework that aims to help society think critically about its complex problems and develop effective solutions. It was developed to address the limitations of traditional linear methods of problem analysis and thinking. According to this concept, it is not enough to study all parts of a system in isolation but rather when solving the problem, it is necessary to consider the various interactions of components [8]. This study explores how systems thinking and Entrepreneurship can be combined to create a more effective and efficient corporate environment.

Systems thinking is described as the collection of techniques, methods and concepts that are utilised to comprehend a phenomenon where there are powerful interactions between the various parts that together form complex systems like those in entrepreneurship and sustainable development [9]. Classic Systems Thinking literature focuses on the balance of forces and counter forces to maintain equilibrium. This helps explain how current social issues are perceived, and how and where these issues are at present. Cabrera et al. [10] have pointed toward an enlightened understanding of the models' complexity and the development of more upgraded mental models. Mental models can be explained as extremely held internal images of how the world operates [3]. One of the most challenging phenomena which is at the forefront is that it is difficult to predict the effects that will be because of changes made. This is because a single change can influence flow, leading to the second, third, and umpteenth sequential consequences [11]. This phenomenon is not widely discussed in entrepreneurship literature, and it means that entrepreneurs' mental models are not fully equipped with the skills to anticipate the consequences of a new product or service when it is launched [1].

Entrepreneurship is often regarded as a system or network of interlinked actors that is related to the complex issues such as sustainability and this topic is rarely discussed in the academic research environment [1]. A system outlook on entrepreneurship is required to consider the various factors that affect the development and operation of a business and also requires the entrepreneur to explore and consider the effects of the system that is being targeted [13], [14].

Morris *et al*. [15] stated that advantage derives in Corporate Entrepreneurship from five crucial organisation capabilities namely adaptability, flexibility, speed, aggression and innovativeness. Organisations that are more flexible, aggressive, fast, adaptable, innovative, and aggressive enough are well positioned not only to adjust to a threatening, dynamic and the complex external environment, but they have the ability to create change in such an environment [16].

3 RESEARCH DESIGN AND METHODOLOGY

Corporate entrepreneurship has various segments, and is considered complex as it involves all divisions within the corporate which contribute to the business functionality.

To study Systems Thinking in this particular corporate, the conceptual model outlined on Figure 1 links the main concepts namely Systems Thinking; Complexity Management; Innovation Dynamics and Managers Thinking Style and the associated research questions were formulated:

1. What are some of the organisational complexities caused by lack of Systems Thinking practices within the organisation's corporate business/entrepreneurship?
2. How are managers affected by maintaining the traditional linear thinking philosophy in the corporate place?
3. Which challenges do the organisation faces with respect to innovation, stakeholders and inter-departmental participation during the innovation process?

Figure 1: Conceptual model for Systems Thinking on Corporate Entrepreneurship.

Research design can be described as the logical sequence that links the empirical data to study's research questions and eventually towards the conclusion [17]. Triangulation method was used to obtain data and the conceptual model was created to answer the research questions.

The research was set and conducted in one of South Africa's largest logistics organisations which has various branches and operating divisions throughout the country. The organisation has assets worth more than R350 billion. It is an organisation with a strong chain of corporate entrepreneurial activities between its six divisions. This organisation made it possible to study the impacts that systems thinking has on corporate entrepreneurship because of its vast operations in the country.

Data gathering was carried out through a survey questionnaire (25 questions) which was sent to different managers within the organisation in different departments and divisions, and 60 valid responses were received (70% response rate). After the results were interpreted from the survey questionnaire, 10 managers from different departments and divisions were sampled for in-depth follow-up interviews using the purposeful sampling technique. Purposeful sampling technique affords one an opportunity to focus more in-depth on a phenomenon and therefore allows one to explore cases rich in information from which one can learn greatly on issues of central or principal importance to the research [12]. The interview respondents were selected on the basis of the departments they represent. Some of the sampled departments were Welding Co-ordination, R&D, Operations Department, Mechanical Design Office just to name a few. These departments were selected to get a broader view from different branches of the corporate so that a broader perspective can be drawn.

Statistical Package for the Social Sciences (SPSS) was used for descriptive statistics for quantitative data and Atlas.ti was used to analyse the qualitative data. The quantitative data paved the way for the collection of qualitative data. The empirical results of the primary qualitative data were linked to the research questions being studied. This was achieved by capturing qualitative data with Atlas.ti, followed by coding and therefore deducing themes from the coded data using thematic analysis.

Due to the reason that this was a case study research, only descriptive statics was used to analyse the quantitative data. The quantitative approach was undertaken to guide what questions should be most focussed on to attain in-depth qualitative data. Construct viability was enhanced by comparing the various interview responses where possible. The authenticity of the results was guaranteed by sternly adhering to the comments and answers given by the participants during the interview process.

Formal ethical clearance from the ethics committee of the university was obtained on 08 August 2022.

4 RESULTS

4.1 Quantitative results

The survey results indicated that there is little trust between management and employees. The command control structure is the kind of structure that aims to control employees and could lead to little trust between the two forces. There is a division on whether management recognises strong job performance (meaning the reward feedback system is not as strong as explained by [3] with over 90% of the respondents having stated that they understand how their work impacts the organisation's business goals. According to the survey results, most managers are not convinced that their leaders/superiors inspire them to seek more of the company vision and this has a negative impact on the organisational performance because leaders are meant to construct, architect and design the systems in the organisation [18].

Most managers agreed that they consider part of their responsibilities as ensuring that they maintain the existing corporate order which is the linear thinking philosophy and maintaining the current functioning system and thereafter letting the system live naturally. This prevents managers from thinking systematically and seeing the bigger picture which results in challenges within the corporate business and therefore hinders the entity's competitive advantage in the external environment

4.2 *Qualitative results*

From the quantitative results, managers were sampled for in-depth interviews of which thematic analysis was used to analyse the data and four themes emerged thereafter. These themes are presented in Figure 2 namely: complexities within organisation, linear thinking philosophy drawbacks, organisational policies, and innovation challenges contributors

- **Theme 1: Complexities within organisation**

This theme is built on sub-themes of trust, strong job performance, and synergy. Trust is one of the most important factors in relationships and this is no different between management and employees. Trust can be eroded by a variety of factors including lack of transparency between two parties, underlying mental models, and even lack of communication.

Lack of trust has been noted to be due to so many dynamics, i.e., employees do not have a sense of transparency from managers and lately, "there has been no communication from management regarding the direction the organisation is taking". When asked if there is trust between employees and managers, one respondent answered:

"I don't think there's any trust, maybe at some levels, there might be some form of trust because of the instability but I think it's in small pockets. At this current stage with restructuring as it is, I don't think anybody can even go to their managers and ask them to explain where they will be five months down the line." (Participant 4, Manager: Welding Engineering, 25/08/2022).

When there is a lack of trust between management and employees, one of the two parties tends to execute the job religiously, simply because they have to, and it's always a matter of 'one needs to cover themselves if something is to happen and with the unions of the workers not as strong as they used to be, there is less trust and as a result, there is more of the disinterest and the indifference behaviour from employees, as one of the respondents said:

"I think in general, there's mistrust. I think it's very subdued because, you know, in the past, in this company, the unions were very strong and that has changed since. And because of that, you know everything is quiet, even though there's mistrust, it's more of a don't care attitude based on there not being sufficient trust." (Participant 1, Manager: Locomotives Business, 31/08/2022).

There also seems to be an issue with how there is a breakdown in communication from the Executive management. It was said that one of the many reasons why there is a lack of trust between management and employees is that there is no alignment. Information gets lost in the communication chain, from the Executives to the senior managers, to the middle managers and finally down to the supervisors. Top management may understand the strategy and the business plan but when the message is passed down, it gets lost in the translation and this creates misalignments and mistrust between the two parties.

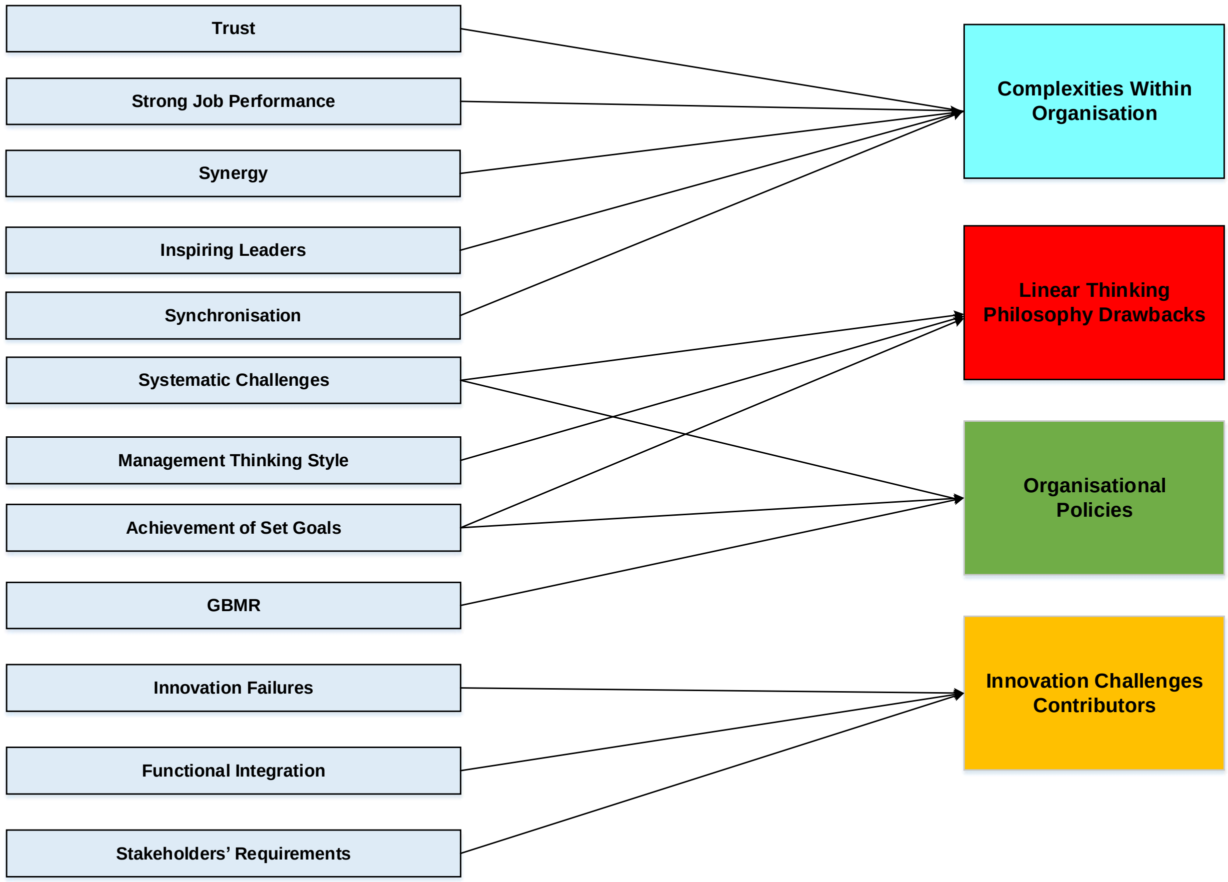

Figure 2: Analysis outcome: Coded data and corresponding themes.

Another pillar that forms part of the organisational complexities is the recognition of strong job performance. Employees tend to thrive when their good performances are recognised and when the opposite happens, the departments and organisation at large start to experience less creativity, intrinsic motivation, and good performance diminishes, short-term thinking arises, and crowding out of good behaviour can also result. From the interviews carried out, it was noted that the organisation has not been practicing such a feedback system for a few years this has demoralised many. One respondent stated that:

"There is no recognition to be honest. A good example is the KPI system that has been implemented over the years. I mean that system is not effective because at the end of the day, even if you score 5/5 on your KPI, you get nothing at the end of the financial year." (Participant 5, Senior Manager: Mechanical Design Office, 01/09/2022).

- **Theme 2: Linear thinking philosophy drawbacks**

This theme is built on three sub-themes namely systematic challenges, management thinking style, and achievement of set goals. Linear thinking has been widely practiced in the industry for a number of decades and it is only in recent decades that Systems Thinking has gained ground in the corporate world. The survey questionnaire for the quantitative data revealed patterns in terms of the maintenance of linear thinking philosophy within the organisation, where most respondents agreed that they consider part of their responsibilities as ensuring they maintain the existing corporate order which is the linear thinking style. One of the challenges with linear thinking is that failures could result, and all the interviewees agreed that keeping to such a thinking style could be detrimental. These failures could be attributed to, but not limited to; the failure to resolve or adapt to a new thinking style, the failure to recognise and resolve systematic challenges.

When the sampled managers were questioned if they experience systematic challenges within their departments, they all agreed with the first respondent sighting that 75% of the challenges being systematic in nature is basically the minimum. These challenges are a huge hindrance to operations resulting in less production and declining profit margins. One respondent stated:

"Even if there is work to do, you don't have spares. You have other issues that stop you today, for example, the whitings are not working, if the whitings work, then we can't do shunting because shunters don't have valid certification." (Participant 1, Manager: Locomotives Business, 31/08/2022).

- **Theme 3: Organisational policies**

This theme was aimed at investigating if the organisation practices the feedback systems; Goals Behaviour Metric Rewards and how the systematically structured policies contribute towards departments not achieving goals. This theme is built on three major sub-themes namely systematic challenges, achievement of set goals, and the Goals Behaviour Metric Rewards.

The metric reward system is a system that influences behaviour of employees. The Goals Behaviour Metric Rewards is a feedback system that reinforces employees positively for profitable behaviour and negatively reinforces the employees for undesirable behaviour. Employees are said to perform better when they feel appreciated, recognised, and even rewarded for good performances. Only two interviewees agreed that the organisation does practice such a system, two respondents stated that the organisation does and does not reward its employees and six respondents disagreed that the organisation practices such a system.

These organisational policies are said to be more high level and though there are those which cater for departmental rewards and these policies are not effectively implemented as far as the hierarchy descends, this was attested by one of the respondents who stated *"The policies are there, more for formalities' sake, they are rarely used and there might be some people who actually use these somewhere in the organisation, but maybe in other operational divisions not here. I actually don't know where these policies are used"*. (Participant 4, Manager: Welding Engineering, 25/08/2022). The reality that these policies are not well implemented or even practiced (for the last 4-5 years) has resulted in so much despondency amongst different teams.

- **Theme 4: Innovation challenges contributors**

This theme is critical in assessing the challenges and hindrances that the organisation is faced with as far as the innovation implementation process is concerned, both radical and incremental. The sub-themes to be explained which have been found critical for this assessment are the innovation failures, functional integration, and the synchronisation of the stakeholders. While investigating the challenges that hinder innovation within the organisation, trends related to the previous themes emerged and all these were understood to be systematic in nature.

During the quantitative data collection, just under 80% of the respondents agreed to be aware of innovation failures that the organisation has experienced. The interviews also revealed that

80% of the respondents know of various innovation failures that have happened due to the silo mentality, lack of synergy, etc as one of the respondents stated:

"Yes, there is one I can vividly think of, the XXX project is a perfect example. The stakeholders in that project did not agree on a whole lot of things, so what made that project fail from the beginning was the planning, giving the project to people who didn't know what they were doing…." (Participant 2, Manager: Welding Technology, 25/08/2022)

One innovation failure one of the respondents spoke about was the failure of XXX project that was designed a year ago. All the work, the design, and the drawings were completed. The design process was completed and commissioned, and it was in 2022 when the project was supposed to be on the prototype stage that there was an announcement of a lack of finances to fund that project. This is due to a lack of synergy and unsynchronised stakeholders between engineering and other departments because there is no understating of the organisation's position. One respondent stated that *"the design was commissioned and completed, but the project still had not come to fruition due to finances, that lack of synergy to understand where we are as a business and if there can be an implementation of this project."* (Participant 5, Senior Manager: Mechanical Design Office, 01/09/2022). This example is one of many which were explained during the interviews and one of the respondents emphasised on the issue of linear thinking being the cause of such failures.

5 DISCUSSION

Data analysis resulted in four different themes which aimed at answering the research questions namely complexities within organisation, linear thinking philosophy drawbacks, organisational policies, and the innovation challenges contributors presented in Table 1 with the research question(s) they address. Each of the themes will be discussed in more detail hereunder.

Table 1: Research questions related to themes.

Research Question	Theme
1. What are some of the organisational complexities caused by a lack of Systems Thinking practices within the organisation's corporate business/entrepreneurship?	1-Complexities within the organisation 3-Organisational Policies
2. How are managers affected by maintaining the traditional linear thinking philosophy in the corporate place?	2-Linear Thinking Philosophy Drawbacks
3. What are the challenges that the organisation faces with respect to innovation, stakeholders, and inter-departmental participation during the innovation process?	4-Innovation Challenges Contributors

5.1 Complexities within Organisation and Organisational Policies

Research question number one was addressed by themes (1) and (3); one of the challenges that the organisation is faced with is the lack of trust between management and employees. This is said exacerbated by the restructuring that is currently underway where no one is confident of the outcome. It was also observed that every time new Executive Management is appointed, there is a reshuffling of individuals which filters down creating instability and mistrust. Systems Thinking comprises of different factors in the workplace and mental models are part of them. Everyone has a mental model based on intuition and this is usually established subconsciously as a result of what is discerned to be the circumstance and cause of a certain event [19]. Good mental models yield positive structures and bad mental models yield negative structures [1], [2]. Based on these statements, there are mental models that have been developed by the employees/managers over time and have resulted in a lack of trust. Employees are reacting to events that they are faced with within the organisation and this lack of trust is an emerging pattern that is characterising the nature of the system problem. When business' KPIs are not as per expectation, managers should embark on reviewing their own mental models to determine if they require modification. Recognition of strong job performance was also one of the factors that have been found to be adding to the organisational complexities. Individuals thrive when they are recognised for good performance, behaviour, and character and the opposite is also true.

According to the interviewed managers, 60% of the respondents agreed that the organisation does not recognise strong job performance and as well as practices the Goals Behaviour Metric Rewards. Rewards form part of systematic anatomy and these are tools that motivate the desired behaviour. Rewards must also be factored within the financial constraints and should be distinctly linked to the behaviour that gave the reward as per Maslow's hierarchy of needs [2]. The lack of recognition of good performance and the reward systems causes unintended consequences such as crowding out of good behaviour, performance decline, and demotivation as shown on Figure 3. To avoid unintended consequences, the organisation should identify the structures and feedback loops that cause such consequences [4].

The organisation is said to have policies that cater to the reward and the recognition system, but these policies are more for formalities as one of the respondents mentioned. Policies should be implemented and if there are hindrances to implementing them, they should be reviewed and revised leading to Rube Goldberg structures as argued [11] as well. Monat *et al.* [2] stated that situations change and when these situations change, the policies become outdated or invalid, so it becomes prudent to review company rules, procedures, policies, incentives, and structures regularly and map out corresponding Causal Loop Diagrams to ensure that intended behaviours are yielded.

Figure 3: Employee Manager Feedback Loop, negatively reinforced because of no recognition and reward (Adopted from [2]).

Fifty percent (50%) of the interviewees disagreed that there is synergy amongst different departments within the organisation with forty percent having agreed that there is synergy. Synergy within an organisation denotes wholeness and the systems approach permits the connecting of objects at various types to a single whole and to organise various types of activities into one complete whole [18]. Synergy requires holistic thinking, centered on system logic and process orientation.

It was also observed during the analysis phase of this research that 60% of the interview respondents disagreed that their leaders inspire them, with some mentioning that some of their leaders are not aware of what the goals and vision of the organisation are. The organisational goals must be well defined because, without the proper definition of the organisational goal(s), the pathway to the future is disorganised. Organisational goals are hierarchical and start at the pinnacle of the organisation such as the Board of Directors, CEO, and President, and filter down through the company [20]. Goals should engage and support each other at all ends. The leader's new role in the organisation is to be its constructor and the systems approach regarding the organisation structurally alters the role a leader plays within an organisation. This was not found to be the case from the analysed qualitative results, and with the quantitative analysis where only 36.07% agreed that their leaders inspire them to seek the company vision. An organisation requires leaders who are charismatic and inspirational toward their followers to seek the vision, and plan the strategy, politics, and structure of the organisation [18]. A manager requires a multi-systematic approach to be able to systematically restructure the old system into a new one. However, according to the survey results that were obtained, 68.85% of the sampled managers agreed that they consider part of their responsibility as ensuring they maintain the existing linear thinking philosophy.

5.2 Linear Thinking Philosophy Drawbacks

The findings on the theme drive towards answering research question 2 which focuses on the management thinking style, systematic challenges, and the achievement of set goals. The management team in this organisation is still focused more on the traditional way of thinking (linear philosophy). This was observed from the quantitative survey results where 68.85% of the sampled managers agreed that they consider part of their responsibility as ensuring they maintain the existing linear thinking philosophy, with over 60% having agreed that they orient themselves to the maintenance of the system and therefore let it live naturally. According to [18], managers orient themselves in such a way because of lack of time, the inability to develop a holistic perspective and because of traditional ways of reasoning.

All the sampled managers for interviews agreed that they are capable of developing a holistic perspective and some attributed such ability to the fact that they have been with the organisation for a long time, and they have learned to create and understand the bigger picture. It's worth noting that even though the managers have got the capability to develop the holistic view, most managers are still linear philosophy minded as was observed during the survey data collection. Organisations are created to accomplish certain results and if such results do not ensure then structures, operational processes, information flow, and interrelations must change to meet the needs [21]. Linear thinking focuses on certain events, it views behaviour generated by a system as driven by external forces, searching for perfectly measured data and seeking to prove models to be true by validating with historical data [22].

All ten sampled managers agreed that linear thinking philosophy could result in failures within an organisation because problems are not fully defined, there is little to no information that is gathered for the problem's solution, there is no formulation of the hypotheses, presumptions, and correctness of the findings are not examined in order to create a solution of the challenges that might be expected during the course of the project [18]. The organisation has suffered so many losses due to its linear thinking style, such as lucrative contracts with competitors and costly resources.

The linear thinking philosophy also results in systematic challenges. All sampled managers agreed that their departments are plagued with systematic challenges and that they do not reach their goals due to low morale amongst different teams, late design changes or changes in User Requirements, etc. An organisation should exercise operational thinking or dynamic thinking that will assist with the evaluation of the multi-loop feedback systems, and the identification and recognition of the delay effect and growth barriers [18].

5.3 Innovation Challenges Contributors

Theme 3 was identified to be critical in assessing the challenges that the organisation faces when they are embarking on an innovative project. Most of the findings that were observed under this theme link back to the linear thinking philosophy that the organisation is more accustomed to. This philosophy results in inherent systematic challenges that have already been discussed and therefore the hindrances in achieving the set goals as all the sampled managers alluded to during the interviews.

Eighty percent (80%) of the managers agreed to be aware of the innovation failures due to various factors such as lack of synergy, lack of effective communication, the practice of linear thinking that does not allow for a complete definition of the problem, etc. Linear thinking does not utilise the system called interactive design. Interactive design is the design of the desired and intended future coupled with implementation procedures, where it is a requirement to define the problem, identify and gathering of information for the problem solution, hypotheses formulation, observation of presumptions, and correctness of findings, and thereafter create a solution [23]. Interactivists are different from proactive and reactive players because Interactivists mainly put focus on the problem, the definition of the problem, its formulation, and the search for its solution. This becomes a critical assessment as it affords the stakeholders an intuitive skill that allows for better creativity which in turn results in a distinctive competitive advantage in the external environment. It is stated that system perspectives on innovation's focal point are the nature and influence of the collaborative character of innovation [24], [25].

6 CONCLUSION

The objective of the research was to determine and study the challenges that are caused by a lack of systems thinking philosophy within the organisation and its daily business activities. The lack of this practice leads to various organisational complexities such as lack of trust due to developed mental models between employees and management, demotivation, and despondency due to lack of good performance recognition and even lack of inspiration from leaders. This calls for managers and the organisation to stop thinking in a linear manner but a Systems Thinking way.

Four themes were identified, and these were aimed at dissecting and answering the research questions. Through the qualitative approach, different challenges were observed that the organisation is experiencing, and these challenges were observed to be mainly because of the linear thinking philosophy. Linear thinking philosophy is static in nature and does not allow for a dynamic approach towards daily activities. This thinking as the name describes (linear) is a straight-line thinking, which views causality as moving one way with each cause self-standing from all other causes [22].

Systems thinking is defined as a language, a set of tools, a perspective that has the ability to usher a holistic view that relationships observed on system components, between such components and the environment are as important as the components themselves [2], [26]. Not only does the external environment requires dynamicity, but the internal environment requires such a thinking style to annihilate various organisational complexities within the organisation. This study proved that there are various challenges within the organisations such as different mental models, and systematic challenges that hinder the departments from achieving their set goals and ultimately the goal of the organisation [3], [9], [10]. Morris *et al.* [15] stated that firms cannot remain static and so they must continually adapt, adjust and redefine themselves as this remains to be the basic principle in a free market economy.

It was found that organisational complexities are exacerbated by linear thinking philosophy because this thinking does not consider the systems methodology in holistic thinking, operational thinking, interactive design and self-organisation as explained by [23] and [26]. Static thinking focuses on certain events and views behaviour created by a system as driven by external forces and this also manifests in innovation failures that have been encountered within the organisation. Systems Thinking places the responsibility for behaviour on internal actors who craft and manage policies and plumbing of the system (i.e., organisational policies) unlike the system being thought of as driven by external factors.

7 LIMITATIONS AND FUTURE WORK

The study targeted a certain corporate organisation in South Africa. Participants in the study were selected using the purposeful technique and various managers from different departments and divisions were selected for different perspectives therefore findings of this study are limited to such an organisation. One other limitation is that the study only targeted managers and not employees and should therefore be used in such context as employees could bring a different perspective from that of managers This was a case study investigation and the case study method by design does not provide generalisation to the population. Further research could try and explore other organisations and industries at large on the effect of Systems thinking on Corporate Entrepreneurship. It is worth noting that other organisations can apply the findings of this study by adhering to the principles of Systems Thinking and as well taking into account how linear philosophy can be detrimental to entrepreneurial activities as seen in this study.

ABSTRACT

South Africa is a world-leading Platinum producer. Most of this mining takes place in an underground narrow tabular setting. Mines are heading for challenging times in the coming years because mines are becoming deeper and more expensive to extract. Technology must be implemented to ensure long-term optimal extraction in these underground mines. The literature indicates that surface mines have seen major production increases where fleet management technology has been implemented and that underground mines were trailing in this technology due to the harsh environment. The author, therefore, investigated how data and fleet management technology could be implemented to improve productivity in underground narrow reef board and pillar mines. The research objective was to develop and define a fleet management system using the systems engineering approach to improve productivity at the Two Rivers Platinum mine and to determine all the aspects to be considered. This mixed methods research used the literature, stakeholder interviews, and tests to design and establish the fleet management system. A case study compared the newly developed fleet management system to the current fleet management processes. The results were encouraging, indicating that cost savings and production increases could be realised.

1 INTRODUCTION

The Platinum Group Elements (PGE) is a scarce commodity and essential in modern advanced technologies and chemistry. The PGE comprise the following metals: Platinum, Palladium, Rhodium, Iridium, Ruthenium and Osmium.

South Africa is a world-leading producer of Platinum (92%) and Rhodium (80%) [1] and all these PGEs are mined from the Bushveld Igneous Complex. Mines must improve efficiencies and reduce costs to ensure that mines can mine at the lowest possible dollar per ounce prices and stay salient and profitable.

The mining industry is heading for challenging times in the coming years [2]: High-grade ore is more problematic to obtain because mines are becoming deeper and more difficult and expensive to extract. Mining companies need to shift to a more technological approach to ensure that long-term, cost-effective production is possible [2].

Two Rivers Platinum Mine is situated in the Steelpoort Valley on the eastern side of the Bushveld Igneous Complex and mines the UG2 (underground two chromite layers) with TM3 (Trackless Mobile Mining Machinery) using the fully mechanised board and pillar mining method. The board and pillar mining method best suit a reasonably vast, flat dipping reef. Optimal results are achieved with a reef at least 2m high [3].

The mine has 153 TM3 mobile machines currently working in the underground mining environment. These machines have intelligent capabilities and can provide valuable information and communicate information to a central data system.

These intelligent capabilities can transfer vast amounts of information remotely from an independent mobile platform to an existing data collection system such as Wi-Fi. This allows the user of the telemetry system the opportunity to receive real-time data from this separate device, as well as the ability to have remote control over this system [4].

This information could improve fleet management, maintenance, overall availability, and the utilisation of trackless machinery. The study will use systems engineering processes and more specific requirements engineering processes to define an optimal underground data collecting and management system and propose an architectural framework (AF) that any low-profile board and pillar mine can use to obtain the most optimal and efficient system. Some verification and validation processes will also be performed on the proposed system to determine if the needs of the stakeholders are satisfied. The system can ultimately ensure that machines can be operated autonomously, but this will not be explored in this study.

The data received from the machines and the proper management of this data could lead to a more efficient and effective mine. The productivity of 10 surface mines increased by between 10 and 20% when intelligent scheduling for underground mobile machinery was applied [5].

No wireless underground data system exists at Two Rivers Platinum to convey the data from the machines to a central point. Wireless networks can facilitate communication and data transfer in underground mines [6]. Still in the current underground environment, communication methods are trailing behind what is available in surface mining applications [7]. This is not solely due to a lack of effort in the underground environment but also the harsh and hazardous environment.

There are also currently no theoretical wireless models available for board and pillar mines with tunnel heights lower than 6m, and this area is not well researched [6]. This is the reason for an investigation in how technology – specifically, data and fleet management technology underground, could be used to reduce costs underground to improve the efficiency and effectiveness of the production machines generating the platinum ore.

1.1 Systems Engineering

The wireless backbone underground, the data sending capability of the machines and the data receiving, analysing and management tool can each be described as separate sub-systems. It can be described as a system. A system is an assembly of different elements that, if put together, achieves results that cannot be produced by the elements alone [8].

Systems engineering and system management is a growing trend in project environments. It changes the management principles from "project-based" to "system based" and improves the rate of overall success in a multitude of industries, including mining [9] [10].

In using a top-down and bottom-up approach when designing a system and by proper assessment of the risks and opportunities, you can ensure that the system performs more effectively and efficiently than a system created on an ad-hoc basis [10].

Various promising technologies and products failed to be implemented successfully [11]. Aerospace and defence manage to accomplish ever more challenging missions and endeavours successfully and remain at the cutting edge of technology through their use of the systems engineering approach [11].

From the literature cited above, it can be concluded that a proper way to introduce wireless technology and a fleet management system underground can be achieved by following a Systems engineering approach.

1.2 Rationale of the research

It can be surmised that Platinum Mining in South Africa is a vital industry and that optimising the production and reducing costs will ensure that a mine stays effective, efficient, and sustainable.

The machinery used at Two Rivers can provide a wealth of data that the mine can use to manage better and utilise the fleet. This can lead to efficiency improvements, reduce costs and move Two Rivers back into the 25 percentile of the cost curve.

No wireless network, data collection system or fleet management system is currently available to utilise the information. From the literature it also became apparent that wireless systems and fleet management in the board and pillar environment are not well researched.

This study contributes to the current body of knowledge. It also is a value-added proposition for Two Rivers Platinum to improve production and quality by managing the production machines, reducing operating expenditure and becoming the preferred mine of choice for potential investors.

The research proposes a combination of subsystems (data, wireless backbone and management tool) to address this problem using a systems engineering and management approach.

The systems engineering approach ensures that a better data collection and management system is produced in the challenging and complex underground mining environment.

1.3 Objectives

The objectives of this research are to develop and define a system using the systems engineering approach to use the intelligent capabilities of machines, an underground wireless network, and a computer sub-system that could better manage and maintain the Trackless Mobile Machinery at Two Rivers Platinum mine.

This system must be able to collect, interpret, integrate, manage, and verify this data continuously. The fleet management system is complex; therefore, the research will explore a systems engineering approach to ensure an optimum product for the end user and all stakeholders. The systems engineering approach will ensure that it can develop, evolve, and emerge into a management tool that any mine- and engineering manager could use to the overall advantage of the mine.

Given the objectives, the research questions are:

1. What aspects must be considered when implementing a Data sending, Collection and Fleet Management System?

1.1. How can systems engineering be used to define and develop the most efficient and effective data collection and fleet management system?

1.2. What organisational design can be used to define and develop the most efficient and effective data collection and fleet management system?

2 LITERATURE REVIEW

The three major subsystems of the underground fleet management project were highlighted, and proposed systems were investigated. The subsystems were identified as the Smart Machine, the underground data network, and the fleet management systems.

It was determined that modern machines, including Two Rivers TM3 machines, are already equipped with sensors and all the necessary hardware to communicate and send data [11].

As per [12] and [13], the onboard systems and the systems implemented in other mines were explored, and the interaction between the various sub-systems was illustrated. Signal strength and environmental challenges were also highlighted as essential aspects to consider for the machine's data-sending capabilities [6].

It was determined that underground data networks are currently not as well developed as the surface areas due to unfavourable and harsh underground conditions [7], [14]. [7] listed all the current types of data network available underground and indicated their preferences for wireless systems above permanent cabled infrastructures, echoed by [2].

A procedure for establishing a Wireless Sensor Network underground was explored by [14]. This system benefits the practical design of underground monitoring systems and applies known systems engineering processes to the environment and the controllable and uncontrollable parameters. As part of the design, positioning the underground nodes was an essential environmental aspect because of the large footprint, tunnel shapes and wave propagation of underground signals. All these aspects must be considered to ensure a cost-efficient system and continue to offer positioning solutions [2].

A data wave propagation solution for the underground board and pillar mines is proposed in [6]. Still, this theory was only tested in 6m high board and pillar tunnels and stated that further study was still needed in lower tunnel height mines. The survey into wireless data network systems for underground mines showed no examples for low profile board and pillar platinum mines where integrated data networks are used.

Very few fleet management systems are currently implemented underground, and this problem was also mentioned by [5], [7] and [15].

Productivity improvements of between 10 and 20% were achieved at surface mining operations using fleet management software and that there is no reason why this cannot be done underground because of the improvements in information and communications technology [5]. An algorithm should be used in a blasting cycle operation [5]. This algorithm considers all the production machines, including LHDs, Rigs, Bolters, and the Charging upcycle [5].

A fleet management system diagram is proposed by [13] and [5]. The Finsch model is attractive because Two Rivers uses the same OEM, and similar fleet management software will be used. The cycle algorithm will be shared with the experts from SANDVIK to adjust the fleet management system to suit the low-profile board and pillar cyclical drill and blast mines.

Lack of fleet management and automated underground mines were also mentioned by [6], [7] and [15].

Formal Systems Engineering Processes in Mining was also researched, and the conclusions were that it is currently only an emerging paradigm and there is presently a gap to explore. The advantages of the process were illustrated by [11], [13], [10], [16] and [9].

Examples are given in [9]that proved that systems engineering processes work better in complex project environments and that better results are generally achieved.

Various systems engineering and management processes were explored, and the author decided that ISO 29148 [17] would be adapted and applied to a new problem. The architectural models for the fleet management system will then be developed, and these models can be used industry wide.

3 PROPOSED MODEL OR CONCEPTUAL METHOD

The conceptual models below were used to answer the research questions. A combination of literature was used to develop a conceptual framework for the concept and development phases of the system.

3.1 Conceptual model for Concept phase of the system

A combination of the table below was used as the framework for the concept design phase of the system.

Table 3.1: Conceptual model for Concept phase of the system

Concept Phases as described in different literature			
ISO/IEC TR 24718-1 (2010:14)	ISO/IEC/IEEE 29148 (system requirements, condensed tasks)	Blanchard (2004:16)	Blanchard Requirement Process (Blanchard, 2004:17)
1. Exploratory research	Identify the stakeholders that have interest in system throughout life cycle processes	Research	Identify Need
2. Concept Selection	Elicit stakeholder requirements	Definition of need	Understand the objectives
Characterize solution space	Define stakeholder requirements	**Conceptual design**	Define the system requirements
Identify stakeholders' needs	Analyse and Maintain stakeholder requirements	Needs Analysis	Consider Alternative Configurations
Explore ideas and technologies	Define system requirements	System Operational Requirements	Compare Test Data With Requirements and Objectives
Refine stakeholders' needs	Architectual design: Define the architecture	System Maintenance Concept	Measured Characteristics
Explore feasible concepts	Architectural design: Analyse and evaluate the architecture	Advance product planning (Plans and Specification	Choose the optimum design
Propose viable solutions	Verification and Validation process		
	Management Process of the system		

3.2 Conceptual Model for developmental phase of the system

This section aims to test, using iterative processes, the best possible configuration to meet the required need. The design should be effective [18] and it should also be efficient.

A combination of the literature above will form the basis of the concept and development activities performed in the conceptual method. The method's output will ultimately be a physical system that could be implemented in the underground environment.

Table 3.2: Conceptual Model for developmental phase

Development Phases as described in different literature			
ISO/IEC TR 24718-1 (2010:14)	INCOSE (2015:71)	Blanchard (2004:16)	Blanchard Requirement Process (Blanchard, 2004:17)
Define/refine system requirements	Prepare for design definintion (1)	**Preliminary Synthesis and allocation of design criteria**	Design the system
Create solution description - architecture and design	Establish design characteristics and design enablers related to each system element	Allocation of performance factors, Design factors and effectiveness requirements	Test the system
Implement initial system	Assess alternatives for obtaining system elements	Allocation of system support requirements	Accomplish System integration
Integrate, verify and validated system	Manage the design	System Analysis	Actual characteristics
Production, Utilisation, Support and Retirement portions of the life cycle will only form part of the Concept and Development stages		**System Optimisation**	Update System Characteristics and Data
		System and Subsystem trade offs	Develop Physical System
		Evaluation of alternatives	
		System and Subsystem Analyses	
		System Synthesis and Definition	
		Preliminary Design - - Performance, Configuration and Arrangement of chosen system (Analyses, Data, Physical Models, Testing etc.	
		Detail Specifications	

3.3 Proposition development to test, verify and validate the system.

After the system has been defined and implemented, the system must be tested, verified, and validated. Null propositions were then formulated. These were used during the validation process to ensure that the suggested system adheres to the stakeholders' requirements and the literature.

The following null propositions were introduced:

- Proposition 1: The current intelligent machines do not have all the sensors necessary and the network sending capabilities to ensure proper fleet management.
- Proposition 2: A mixture of wired and wireless technology cannot be used as the backbone of the data network system.
- Proposition 3: The fleet management systems currently in use on the massive ore body mines cannot be adapted and used on a board and pillar operation.
- Proposition 4: The fleet management system cannot improve the productivity of the mine by 10 to 20%
- Proposition 5: Productivity cannot be increased by improving the availability and utilisation of the machines through continuous condition monitoring using the fleet management system.
- Proposition 6: Face time cannot be improved by determining the whereabouts of a machine underground and recording the productive start and stop times of a machine. There is not a direct correlation between more face time and productivity.

The propositions formulated above will be refined later in the process and validated or falsified as part of the results section.

4 RESEARCH METHOD OR APPROACH

The approach to answering the research question was a mixed methods using Design Science Research (DSR) [19]. DSR combines the development of theory and research intervention to answer real-world problems [20]. The method also entails reflecting on the results, learning, and validating as the research continues [21]. This, as explained, was done to get a more holistic view of the research problem because the qualitative and quantitative approaches complement each other. Design is the purpose of the study, and semi-structured interviews and experimental methods will be used to collect the data.

The DSR model shown in Figure 1 was adapted from [22]. The qualitative and quantitative steps are illustrated below.

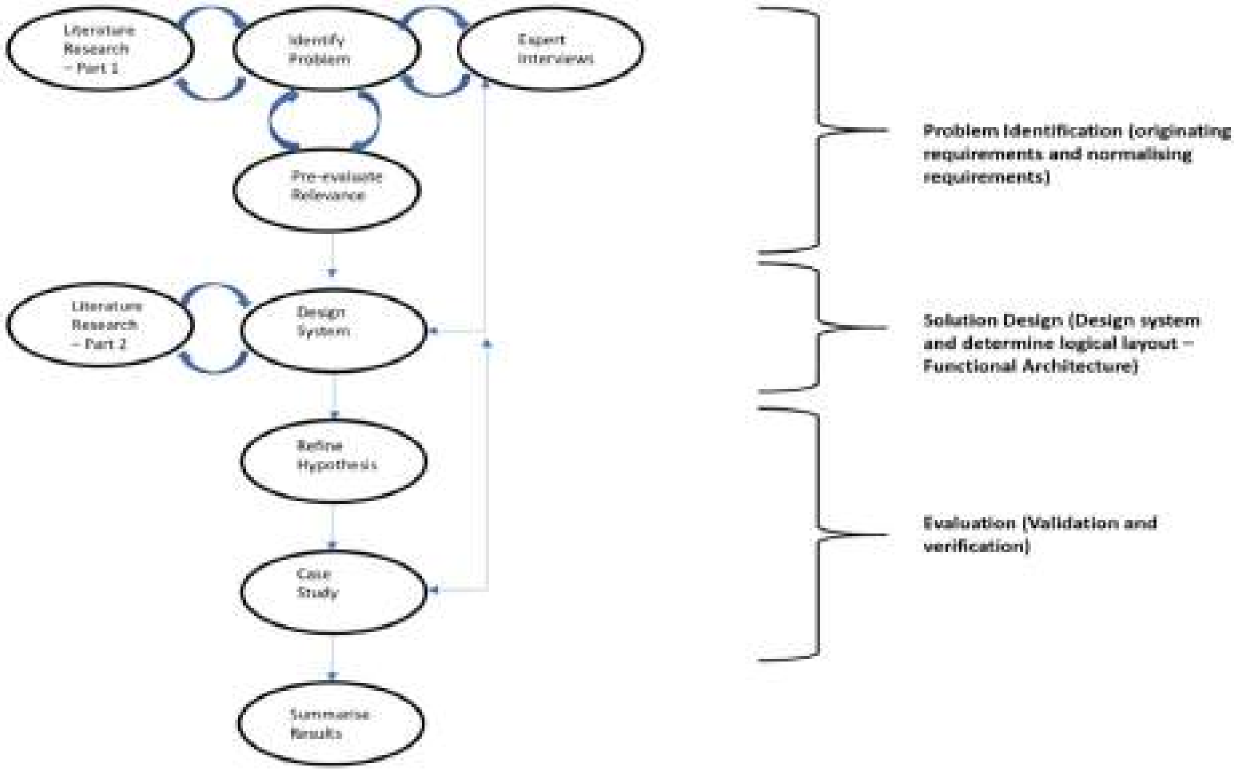

Figure 1: DSR Process (Adapted from [22])

A sequential exploratory design mixed method process was followed where qualitative methods were used first and then quantitative methods; there was not a dominant method because both were equally important to finish the study.

The qualitative methods included semi-structured expert interviews to define the requirements and all the inputs from the owners-, design-, manufacturing- and operations/Support stakeholders. Some aspects of the literature reviewed were also included in this step to define the problem correctly and to create the originating requirements.

A quantitative approach then completed the requirements engineering steps and break up the system into decomposed and normalised requirements.

After this step, inputs were again obtained from the stakeholders to ensure that the requirements were acceptable; this iteration was followed until a good list of requirements was determined. This ensured that the requirements were pre-evaluated, and the relevance and workability of each condition was determined.

The next step was a quantitative step where the system and all its sub-systems were designed to define the architectural framework. In this Solution design stage, the logical layout of the solution will be proposed. This solution was tested and optimised with the inputs from the literature as well as expert interviews.

Propositions were refined to align with the results gathered above.

The next step is to do a case study on the system and to note the results obtained.

5 RESULTS

Sub-system requirements were established using literature, with contextualisation of the problem. Literature findings were shared with mine and industry experts in data networks and fleet management, assessing requirement relevance. This led to problem identification and solution generation. The requirements process aligns literature, stakeholders, and researchers, ensuring an ideal and future-proof system. The iterative problem identification process is depicted below.

The following summarised requirements were gathered for each sub-system. These include inputs from experts, stakeholders, and literature for each sub-system:

5.1 Intelligent machines.

- The TMM machines already have the necessary telemetry to measure condition monitoring parameters.
- Intelligent machines already have a sensor data collector Controller Area Network (CAN) bus to receive all the information from the telemetry.
- Legacy machinery has sensors but no collection method. An Internet of Things (IoT) hub was suggested as a date aggregator.
- The IoT hub was suggested for both legacy and intelligent machinery. The reasoning was that an IoT hub identifies data and arranges it through artificial intelligence, making it more understandable. The IoT hub shall allow other technologies onto the machine, such as Personnel Detection System (PDS), Vehicle Detection System (VDS), Lidar, Camera systems etc.
- The Newtrax vehicle device was recommended as a solution. It is an Original Equipment Manufacturer (OEM)-approved IoT hub, and it fits all the requirements.
- The IoT hub shall be easy to install. The stakeholders noted that initial installation takes 12 hours and replacement takes an hour.
- The device shall hold onto information until data network coverage is detected and dump all the information.
- The device shall withstand the following harsh environmental conditions:
  - Ingress Protection 67 (IP 67) or a better-rated enclosure for the IoT hub to withstand dust, water, heat, and other environmental conditions.
  - Impact protection (IK 10) to withstand the concussions and blasting of the underground environment.
  - Military Standard (MIL-810M) specification ensures modularity and quality, operating in the harshest conditions and quickly achieving interoperability between components.
- Delay in transmission between the machine and the data network shall be between 0 and 5 seconds.
- The signals from the interface IoT hub shall not interfere with any other system.
- The Signal shall be relayed up to 60m if line of sight is available.
- The system shall communicate with various network configurations. 2.4 – 5 GHz and Wi-fi 6 technology was suggested by the stakeholders.
- The machine shall have a (Graphical User Interface) GUI that is interfaced with the IoT hub and indicate to the operator when there are problems and for communication purposes to the control room.

- The IoT hub and data network shall determine the positioning of the machine in the underground environment,
- The system shall be supported. Maintenance, availability, and supportability were listed as requirements.
- The IoT hub shall have a lifespan of between 2 and 5 years.

These requirements were used as the foundation to design the intelligent machine interface.

5.2 Data network

Tests were conducted on the mine to determine what data network configurations would work. These included:

- Bluetooth tags were tested as a data network option; this network layout only addressed the positioning requirements. This system as a solution was discarded.
- Data transfer over the leaky feeder system was tested. This network layout was expensive; only a small data package could be sent, and negative influences on the communication systems and proprietary monopolistic concerns made this system unsuited.
- Long-Term Evolution (LTE) networks performed the best of all the networks if tested in a straight line. Still, the contours of the tunnels, the 2m height and severe undulations in the underground environment caused signal attenuation. The signal propagation around corners was untenable, which could only be mitigated by installing an LTE unit per board. This was not a good solution as only the roadway is open in the board and pillar section, and the rest is packed with waste. The solution was discarded because of these concerns.
- Fibre backbone and Wi-Fi nodes were tested. Stability and repeatability were achieved with this configuration, and because of the vast distances to be covered, this system was seen as the only real solution. Requirements were therefore limited to fibre backbone and wi-fi nodes in the section.

5.2.1 Data network requirements

The following requirements were determined for the data network using the literature and stakeholder inputs.

- Fibre shall be used for the backbone.
- Wi-fi nodes shall be used in the section.
- The stakeholders and subject matter experts shall determine the layout of the network backbone and wi-fi nodes.
- A traditional spliced fibre, network switches and fibre nodes were measured against a Passive Optical Network (PON) system. The PON system was inexpensive, easy to install, modular, upgradeable, uncomplicated, robust, with few components, and complied with most requirements stipulated by Literature and stakeholders. The PON shall be used.
- Ease of deployment was stated as a requirement. The modularity of the PON system addressed this.
- Interfaces shall be easy to install. Plug and play are suggested.
- The environmental considerations shall be:
  - IP 67 or better-rated enclosure and interfaces for the systems to withstand dust, water, heat, and environmental harshness.
  - IK 10 impact protection to withstand the concussions of the underground environment.
  - MIL-810M specification ensures modularity and quality, operating in the harshest conditions and quickly achieving interoperability between components.

  - The network shall be installed where the underground environment cannot damage it.
- The data network shall cover the entire production areas; this includes production panels, waiting areas, production tips and workshop areas. A 12 – 24 node configuration shall be used. This ensures triangulation and total coverage.
- The data network shall be able to provide power to the components in the harsh and remote underground environment.
- Normal connection types and commercially sourced equipment shall be used for the network. This will ensure the maintainability and supportability of the system. Commercially available equipment is also less expensive than a bespoke system and is easier to obtain.
- The network's lifespan shall be 2 – 5 years to ensure economic payback on the system.
- The system shall connect with intelligent machines.
- The network shall have Wi-fi 6 capabilities and a 2.4GHz to 5 GHz frequency range. This will ensure smooth interfacing with the IoT hub.
- The data network shall have a bandwidth of 10GB/s system. This bandwidth is not needed for telemetry because the data packages are relatively small. Still, the bandwidth must be sufficient for voice-over IP and video-sending capabilities that might be required in later projects.
- The system shall segregate different signals on the data network using Virtual Local Area Network (VLAN). Telemetry data shall be ranked as critical information because of the importance of the production information.
- Network spares shall be available on the shelf. The lead time on components shall be less than three weeks. The supplier of the data network shall be a reputable company and have a track record in data networks.
- A maintenance system shall be established, and labour shall be sourced to maintain the system.
- The data system components shall be modular, and components shall be easy to replace.
- The modularity of the components shall also ensure that they can be easily upgraded if newer technology arrives.
- The data network shall be fit for purpose and only have the necessary components to ensure operability.

5.3 Fleet management system requirements

The Fleet Management System (FMS) uses the two sub-systems above, and the following requirements were listed from the literature and stakeholder inputs:

- The FMS shall manage the underground fleet same as surface operations.
- The FMS shall be able to flag any mechanical problem on a machine.
- The FMS shall be able to flag issues with the operation of the machine.
- The FMS shall measure availability of machines.
- The FMS shall measure utilisation of machines.
- The FMS shall calculate Mean-Time-To-Repair (MTTR) and Mean-Time-To-Failure (MTTF) automatically.
- The FMS shall execute as close as possible to real-time.
- The FMS shall be able to indicate the positioning of the machines underground.
- The Graphical User Interface (GUI) shall relay machine info to the operator and send responses to surface.
- The FMS shall determine when machines are due for service.
- The FMS shall display information visually through graphs, charts, and dashboards.
- The FMS shall be secure.
- The FMS shall be supported.

- People shall be trained in maintaining and operating the FMS.
- The FMS shall measure machines' aspects determined by breakdowns and leading indicators.
- LHD shall measure any of the 36 node sensors.
- Rigs and bolters shall measure percussion hours.
- Operation time and face time shall be determined by the system.
- The FMS shall adapt to changes and shall be fully customisable.

5.4 Solution Design phase and logical layout

A logical system layout was determined through iterative methods involving the requirements listed above and solutions offered by system experts.

The results of the solution design and logical layout are summarised below.

5.4.1 Intelligent machine IoT hub.

- The intelligent machines already have all the sensors to facilitate condition monitoring.
- The legacy machines have all the sensors but no data aggregation system. The literature and the stakeholders suggested an IoT hub. The IoT hub is advantageous, even on intelligent machines, to serve as an interface between multiple technologies that might be added to the machine. The hub also serves as a CAN bus replacement on the older type of machinery.
- The research only concentrated on the interface between the machine and the data network system.
- The Newtrax Vehicle Device was suggested by the stakeholders, as it is an Original Equipment Manufacturer (OEM) approved and does what was required from the stakeholders and the literature. The flow diagram between the machine and the data network is illustrated in Figure 2.

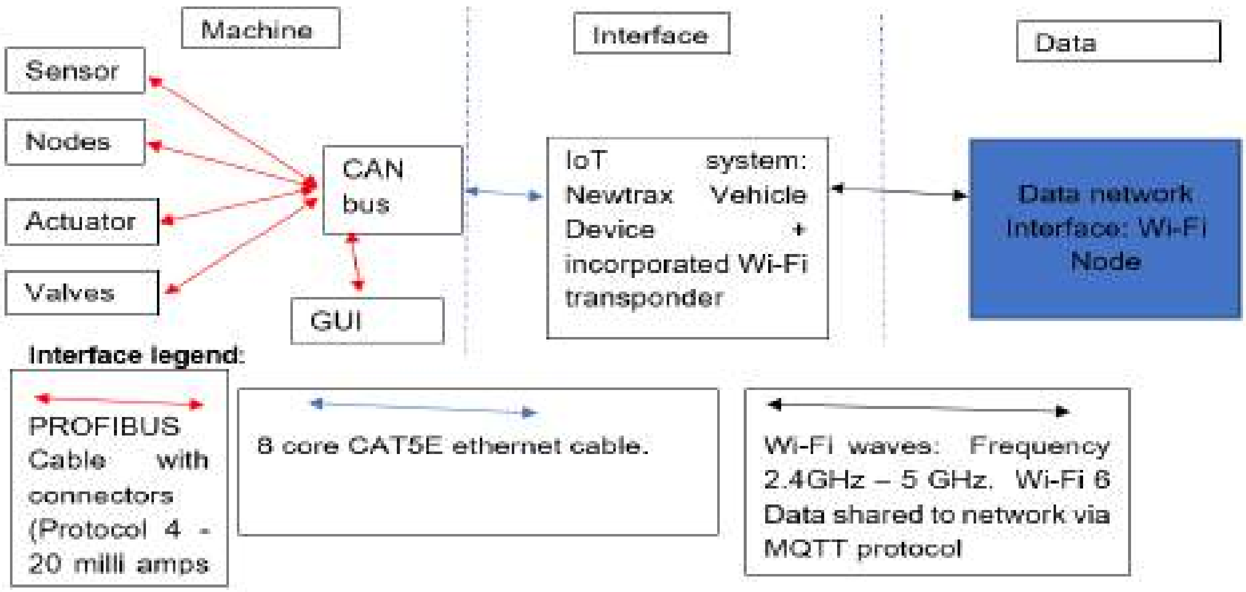

Figure 2: Flow diagram of an intelligent machine system indicating the interfaces

The IoT hub was tested, and up to 140m of transmission distance was achieved.

The hub connected freely to the data network when available. It also dumped the data when the data network was available.

5.4.2 *Data network system*

- The logical layout of the data network system was determined by testing the system underground and optimising the configuration.
- The initial plan had several access switches and aggregation access switches included in the network line after every length of the Gigabit-capable passive optical network (GPON) cable.
- There were also two distinct types of GPON cables, the 1 GB/s type, that were tested between the Optical Distribution Network (ODN) and Optical Network Unit (ONU) components and the 10 GB/s types.
- Extension plugs on the GPON cables made the aggregation access switches and access switches redundant.
- It was also decided that the 1 GB/s GPON is unnecessary and that the 10 GB/s will be the only distribution cable.
- The extension plugs on the GPON saved money due to removing the aggregate and access switches.
- That left the system with only three major electronic devices (Optical Line Network (OLT), ONU and wireless access points).
- The final logical flow diagram of the data network system is indicated below. It complies with the requirements and what is specified in the literature.

The data network in Figure 3 was tested using a layout derived by this study. Many iterative processes have been followed before the system design was determined. The 24 nodes' grid is approximately 30 meters apart, and tests illustrated that proper coverage of the entire section, as stipulated in the requirements, could be obtained using this layout.

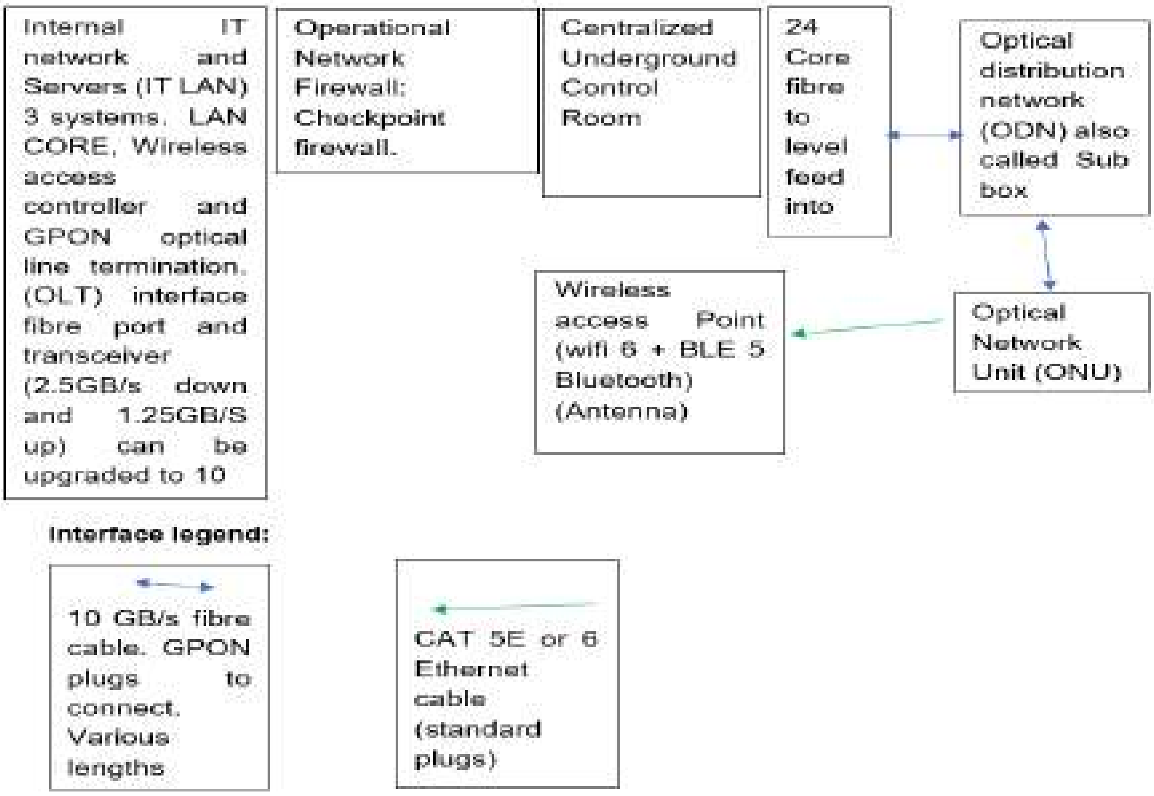

Figure 3: Flow diagram of a data network system.

All the verification processes were done on the system requirements as stipulated. And the stakeholders demonstrated, tested, and analysed each requirement to comply with the verification and validation requirements. Each test was met, and the system did what it set out to do.

The results and layout are the conclusions of multitudes of tests conducted on the mine since 2012, and the layout gave the most optimal results when tested.

5.4.3 Fleet management system

- An assumption was made in the study that OEM fleet management systems prevalent on massive ore body mines will be used to manage the fleet underground; this was not the case; these products are still in the development phase for the low-profile machinery.
- The researcher and stakeholders opted for their developed system.
- In the results, the stakeholders decided on a fully customisable mine-produced system. They used cloud-based technology and Grafana visualisation programmes to indicate the health of the machinery.
- This ensures that the system is fully customisable.
- The logical flow of the system is illustrated below.
- The system of systems was tested in Level 9 on Main Decline as a Proof of Concept. The intelligent machine, Data network and Fleet management system were configured precisely as illustrated above.
- The results conformed to the requirements as anticipated, and the system operated as intended.
- The systems engineering approach will ensure that the system is functional, economical, sustainable, reliable, obtainable, maintainable, supportable, survivable, modular, upgradeable, durable, and fit throughout the system's lifecycle.
- All the verification processes were done on the system requirements as stipulated. And the stakeholders demonstrated, tested, and analysed each requirement to comply with the verification and validation requirements.
- Test results are available for the data network and IoT hub tests performed on the intelligent machines.

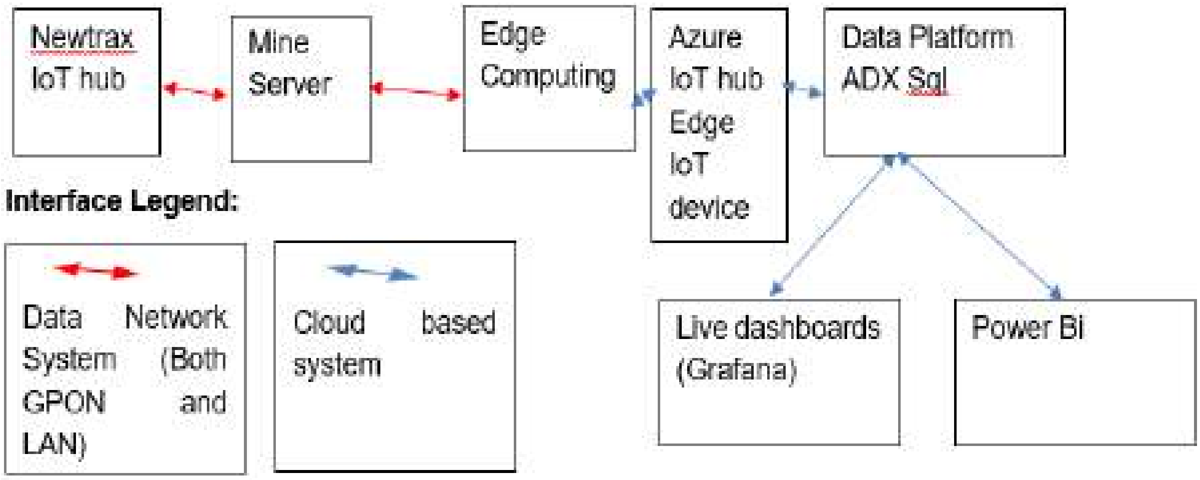

Figure 4: Flow diagram of a fleet management system.

5.5 The case study (Old manual system vs new fleet management test)

The current Two Rivers Platinum condition monitoring system was determined by conducting interviews with the engineering planning department, engineers, and production personnel. It was determined that the current system is very labour intensive and that many manual inputs must be included to calculate and track all the machine condition monitoring and production monitoring aspects on the mine.

The case study focussed on hour capturing of machines, breakdown procedures, productivity, and face time procedures and how the location of machines was determined.

A breakdown of Load Haul Dumper (LHD) 184 was also tracked to explain the current procedure. Each of the aspects of the current system above was compared to the system as it should be if fleet management is implemented.

The case study also served to validate the system and all the requirements. The requirement of the fleet management system was validated and verified. The verified requirements that were tested and validated are tabled below.

Table 5.1: Fleet management requirements

Requirement	**Literature or Stakeholders' requirement?**	**Verification and Validation**
Manage the underground fleet same as surface operations	[5] and stakeholder requirement	Demonstrate
Must be able to flag any mechanical problem on a machine.	[13], [7] and stakeholder requirement	Demonstrate
Must be able to flag issues with the operation of the machine	[13], [5] and stakeholder requirements	Demonstrate
Measure availability of machines	[23] and stakeholder requirements	Demonstrate
Measure utilisation of machines	[23] and stakeholder requirements	Demonstrate
Determine MTTR and MTTF figures automatically.	[23] and stakeholder requirements	Demonstrate
As close as possible to real-time	[5] and stakeholder requirement	Demonstrate
Must be able to indicate the positioning of the machine underground	[5] "Interaction with TMM equipment", [13] and stakeholder requirement	Demonstrate
GUI to relay info to the operator and set responses to surface	[13] and stakeholder requirement	Demonstrate
The system must determine when machines are due for service	[13] and stakeholder requirements	Demonstrate
The system must display information visually through graphs, charts, and dashboards.	Stakeholder requirement	Demonstrate
The system must be secure.	[17]	Analyse
The system must be supported.	[17] [18]	Analyse
People should be trained in the system	[18] p.37	Demonstrate
The system should be able to measure machines' aspects determined by breakdowns and leading indicators.	Stakeholders	Demonstrate
LHD measure any of the 36 nodes sensors	Stakeholders	Demonstrate

Requirement	Literature or Stakeholders' requirement?	Verification and Validation
Rigs and bolters should measure percussion hours.	Used for efficiency calculations and face time calculations. [23] [24] [25]	Demonstrate
Operation time and face time to be determined by the system	[24] [25]	Demonstrate
The system must be able to adapt to changes and be fully customisable	Design attributes - [18] p.37 and stakeholder requirements	Demonstrate

The new proposed fleet management system results are encouraging, and all the requirements are met during the case study. The new fleet management system:

- Makes the filling of checklists redundant to update the hours of each machine.
- Labour required to capture machine-hour readings can be reduced or applied elsewhere. The system reads the machine hours automatically.
- The fleet management system updates the hours in the Centralised Asset Management system (CAMS) and Delta. Availability, utilisation, MTTF and MTTR calculations can be updated constantly for each machine, and trends could be established automatically. Manual inputs into excel sheets and the labour required to perform these inputs are no longer needed.
- Breakdowns do not have to be communicated to the control room; the system does it automatically and gets flagged immediately in the control room.
- Time off is accurately captured, improving the data's integrity.
- Breakdowns can also be prioritised immediately, and the control room can already tell the artisans what the telemetry is indicating and what parts will be required.
- The system automatically registers when a machine starts working, and the trends will be documented throughout the shift.
- Face time of machines can be tracked, and the trends could be used to improve and manage the productive time of machines. Manual call-ins from underground by the Shift boss and artisan to the control room operator are no longer required to state when a machine starts working.
- The wi-fi node's IP address is superimposed on a plan. Finding machinery underground will no longer rely on writing the location of a machine on a whiteboard on the surface at the end of the shift.
- The case study verified all requirements stipulated by the literature and stakeholders to prove the concept.
- The fleet management system is fully customisable, and the immersive behaviour of the system is guaranteed.
- The system conforms to all the requirements as prescribed.

5.6 Proposition Testing

Some limitations were that there is only a short time allowed to test the results in mining environments. Longer-term test results will be available in the future. The propositions testing is discussed below, but longer-term tests will demonstrate what the impact will be.

5.6.1 Propositions of improvement

The following propositions was stated in the research, and the results of the proposition validation or disproval thereof will be listed after each statement.

- Proposition 1: The current intelligent machines do not have all the sensors necessary and the network sending capabilities to ensure proper fleet management. The research proved that telemetry and sensors are available on all machines, thus this proposition is false.
  - Thus, the alternative proposition is accepted: The current intelligent machines have all the sensors necessary and the network sending capabilities to ensure proper fleet management.
- Proposition 2: A mixture of wired and wireless technology cannot be used as the backbone of the data network system. LTE networks did not work in the board and pillar set-up, and because of the vast distances to be covered, a combination of fibre and wi-fi nodes was suggested. This echoed [2] that stipulated cost-efficient coverage with a hybrid solution.
  - Thus, this proposition is rejected, and the alternative is accepted: A mixture of wired and wireless technology can be used as the backbone of the data network system.
- Proposition 3: The fleet management systems currently in use on the massive ore body mines cannot be adapted and used on a board and pillar operation. The fleet management system provided by the OEM is more suited for massive ore body mines, and the board and pillar system is still under development.
  - This proposition is weakly accepted. It can be concluded that an own adaptable system is more advantageous.
- Proposition 4: The fleet management system cannot improve the productivity of the mine by 10 to 20%, as per [5].
  - This proposition cannot be proofed or rejected. Initial results from the case study show that productivity might improve.
- Proposition 5: Productivity cannot be increased by improving the availability and utilisation of the machines through continuous condition monitoring using the fleet management system.
  - This proposition cannot be proofed or rejected. Initial results from the case study show that productivity might improve.
- Proposition 6: Face time cannot be improved by determining the whereabouts of a machine underground and recording the productive start and stop times of a machine.
  - This proposition cannot be proofed or rejected. Initial results from the case study, shows that there is a direct correlation between more face time and productivity.

6 CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusions

The objective of the research was to develop and define a system using the systems engineering approach that uses the intelligent capabilities of trackless underground equipment, a suggested data network, and a to-be-determined fleet management system that can be used as a business solution at Two Rivers platinum to manage better and maintain trackless mobile machinery.

The conclusion, in short, is that a fleet management system was developed using a Systems Engineering approach. The stakeholders and the literature specified the system's requirements, and these attributes were incorporated into the designed system as presented. Each sub-system's needs and the overall system were verified and validated. A case study was performed to test the system's capabilities, and the results indicated that production improvements and labour savings are likely if the system is fully implemented. The aspects one needs to consider when implementing data sending, collection and a fleet management system in a board and pillar mine were addressed through the research and will give future researchers an excellent foundation to work from. The enterprise portion of the systems engineering process has not been addressed and must be addressed in future research. If the management of the system is defined correctly, the project can be implemented, and success will be achieved.

6.2 Recommendations

- The scheduling of the fleet and reference back to the monthly planning was not addressed yet, but all the systems are adaptable to address this requirement; the IoT hub on the machine also ensures that more technology and different systems could be incorporated into the machine. Further work is needed in this area.
- Long-term testing must commence on the designed system to determine if the production's 10 – 20% improvement could be achieved (Proposition 4).
- Based on the labour savings noted in the case study, the system will reach its payback period in less than two years. It is recommended that the system be implemented to optimise the condition monitoring of machines. The scheduling portion can be added later, and the system is ready to accommodate this.
- The enterprise aspect of the system must be done to determine how the system will fit into the organisation and to address the systems engineering management process. It is recommended that SEMBASE theory be applied to the problem.
- Further development and optimisation of the fleet management visualisation dashboards are recommended to make them more user-friendly and easier to interpret.
- An evaluation plan for the evaluation of proposition 5 and 6 needs to be drafted and implemented.

ABSTRACT

The South African Local Government is currently experiencing a backlog in providing basic services to its citizens due to financial constraints, lack of planning, poor project management and integration between sector departments. The South African Local Government also needs a centralised and automated system that can track and report how far the government is in delivering basic services in its local municipalities. The Bill of Rights lists the following as the basic services everyone must have access to health care, clean drinking water, sanitation, electricity, waste removal/management and basic education. This research focuses on a future service delivery tracking and reporting system that can be used to capture data on how far the local government is in achieving its goal of ensuring that everyone in South Africa has access to essential services.

Relevant literature reviewed for this study includes literature on local government, service delivery, service engineering, and systems engineering will be sought in books, research journals and articles and government reports that have been published. The knowledge gained from the literature review and the concept model development led to four research propositions. The results from the proposition evaluation showed that the South African municipalities and sector departments use different tracking and reporting systems. There is a need for a centralised tracking and reporting system. The results also showed that this system would benefit all three spheres of government (national, provincial, and local.)

Keywords: basic services, systems, households, service delivery, local government

1 INTRODUCTION

The Bill of Rights, as enshrined in the **Constitution of the Republic of South Africa, 1996**, makes provision for basic rights that include the right to access basic services. Service delivery is informed by various pieces of legislation, the custodianship of which lies with different sector departments. Furthermore, the Constitution categorises government into three spheres (national, provincial, and local) with clearly defined structures and roles. These three spheres of government are distinctive, interrelated, and interdependent as such; they must work together in a cooperative governance system prescribed by the Constitution.

The provision of basic services to communities is assigned to the local sphere of government as prescribed in section 152 of the Constitution, which mandates municipalities to provide services to communities sustainably. The Bill of Rights lists the following as the basic services everyone must have access to health care, clean drinking water, sanitation, electricity, waste removal/management and basic education.

Oversight on the performance of municipalities on the mandate of basic service delivery is done through structures established through the **Intergovernmental Relations Framework Act, 13 of 2005**, which provides for the establishment of intergovernmental structures that are meant to, amongst others, "discuss the performance in the provision of services in order to detect failures and to initiate preventive or corrective actions". This is to ensure coordination, alignment, and integration of government priorities across the three spheres of government.

Sector departments develop and fund programmes to address the need to deliver basic services. In turn, municipalities implement these programmes as service delivery projects, such as improving access to running and potable water, primary health care and housing. Even though there might be backlogs against government-set standards and priorities, there are currently many projects that have been completed such that the public has access to services intended from the implementation of those projects. However, sustainability over the long term is not guaranteed because, amongst several reasons that may burden the ability of municipalities to deliver services efficiently, there need to be systems in place to manage population growth and an influx of people at urban centres. There also needs to be a centralised management system that tracks and reports on implementing basic services in local government.

The research will focus on managing a service delivery tracking and reporting system that can be used to acquire data on how far the local government is in achieving its goal of ensuring that everyone in South Africa has access to basic services.

1.1 Research objectives

The South African Local Government is currently experiencing a backlog in providing basic services to its citizens due to financial constraints, lack of planning, poor project management and integration between sector departments. The South African Local Government also needs a centralised and automated system in place that can be used to track and report on how far the government is on the delivery of basic services in its local municipalities.

The following objectives will address the research problem:

1. To determine if there is a centralised, automated system that is used by local government to track and report on the provision of basic services in municipalities.
2. To determine if municipalities and sector departments know the number of households with access to basic services.
3. To determine the components required for a centralised, automated service tracking and reporting system.

2 LITERATURE REVIEW

2.1 Local government

The South African local government is grappling with service delivery problems such as inadequate housing, lack of healthcare facilities, and increasing levels of unemployment. The Intergovernmental Relations Framework Act 2012 can be used to ensure integration between the three spheres (national, provincial, local) of government to solve service delivery problems. It also shows the importance of integrated planning across the three spheres of government to improve cooperative governance. “It embodies an approach by which the three spheres of government and state entities work in unison in an impact-oriented way, and where there is higher performance and accountability, for coherent service delivery and development outcomes” [1].

The aspect of accountability in the service delivery continuum cannot be overemphasised. Social accountability, which is about citizens of local government holding public officials accountable for their responsibilities, can be used as a performance management tool [2]. Therefore, citizens need to be part of stakeholder discussions to express their concerns and be actively involved in assessing the performance level of service delivery in the municipality [2].

2.2 Provision of basic services

The government of South Africa should provide its citizens with the surety of continuous provision of basic services irrespective of their cultural and social background. These services must be affordable and easily accessible to all. Service delivery is part of a multifaceted relationship between the citizens and the government [3].

The General Household Survey report [1] shows that there have been remarkable improvements in providing basic services (sanitation, electricity and water) to households that did not have access to basic services previously. Addressing the number of service delivery backlogs is a crucial measure for evaluating a municipality's performance. It shows that municipalities still deal with the challenges of providing access to reliable basic services and a high-standard [1].

The perennial challenges of unserved communities interrupted services, and poor management of infrastructure projects leading to underspending leads to a decline in public trust, hence the increase in unprecedented service delivery protests and some communities taking it upon themselves to repair ailing infrastructure then billing the municipality for it. Statistics indicate that although a significant number of households have been shown not to have access to basic services, most of these households are mainly in the outlying rural areas where the cost of infrastructure provision is exceptionally high [1].

2.3 Management system

Definition: “A management system is how an organisation manages the interrelated parts of its business to achieve its objectives. These objectives can relate to several different topics, including a product or service quality, operational efficiency, environmental performance, health, and safety in the workplace and many more” [4].

A service system entails the arrangement of resources, organisations, and collective information from the service providers and their customers, to create value for the customer. [5]. The system contains a network of resources such as people, technologies, organisations, and information [6].

National and local governments worldwide are under pressure to deliver services more efficiently at a lower cost, and they have identified e-government as an option, both commercially and politically [7]. The application of e-government in government institutions has the following benefits [7]:

a. improved delivery of basic services to citizens,
b. enhanced interactions with business and industry,
c. citizen empowerment through access to information

2.3.1 Gaps identified in the existing local government systems

The South African government has yet to expedite service delivery in local governments. It is appropriate to assume that introducing a fittingly designed corporate governance system that reflects the realities of all local municipalities is a suitable substitute to simplify, develop and sustain service delivery. The literature also indicates the following gaps:

a. There needs to be an integrated service management system that measures basic service delivery performance on a regular basis.
b. There is a need for regular monitoring and evaluation to improve service delivery and check if they meet the service users' requirements. This requires a real-time, accurate, evidence-based system that guides corrective actions to be taken where there is underperformance and dealing with backlogs.
c. There is a lack of infrastructure, resources and fiscus in rural municipalities to implement quality service delivery.
d. There is a shortage of professionals in the service delivery industry that know how to analyse, break down a system and develop a new one that suits the customers' needs.

The implementation of E-government systems in developing countries such as South Africa is still low, and this indicates that there is a need to explore numerous approaches that can be used to provide basic services to communities through various avenues but in a transparent and integrated manner. The purpose of the system would be to improve collaboration between the public and private sectors and citizens through transparency in government planning. Finally, it would improve the quality of information and reduce data handling by multiple stakeholders.

3 CONCEPTUAL METHOD

The construction of concept maps is an excellent way to offer a preliminary organisation of knowledge and to structure an understanding of how a dissertation topic will be approached [8]. A concept map offers a tool to draw a plan for approaching an investigation within a specific theoretical framework [8].

The Nordic Model was developed to measure service quality. The model was created in 1981 by a Swedish firm that deals with services. This model indicates that service quality has two variables: technical quality and functional quality [9]. The technical factor refers to what the customer will receive in the process, and the functional factor refers to how the customer will receive the service. The SERVQUAL model, also known as the 'GAP MODEL', was developed by Parasuraman in 1985 as another model for measuring service quality [9]. For a customer to be satisfied with the level of service they are receiving, it has to meet or exceed their expectations. However, if the level of service is below what they had expected, then the customer is dissatisfied [10].

The District Development Model is an operational method created by the South African government to ensure that the three spheres (national, provincial, local) of government are working in unison to operate at a high-performance level and have accountability for the provision of effective service delivery. The model will also be used to improve planning and budgeting across all three spheres of government through integration and coordination [11].

3.1 The link between the current models

The Nordic, GAP, SERVQUAL and DDM models can be linked or merged based on the following [12]:

a) The Nordic model focuses on the technical factor, which is what service the customer will receive. It can be linked to GAP 1(Customers' expectations: Managements' perceptions) because it refers to the customers' expectations of the kind of service they want. SERVQUAL Reliability dimension is linked to these as it speaks to the capability of the service provider to provide what the customer wants at the same consistency and time.
b) The WHAT part of the Nordic model can also be linked to GAP 5 (Customer's expectation – Perceived service) of the customer, wherein the focus is on seeing physical evidence of the service they paid for and whether they are satisfied.
c) The HOW part of the Nordic model, which is related to the functional factor of how the customer will receive the service, is linked to GAP 4(Service delivery: External communications) and GAP 5 because they speak to how the service will be provided, how the organisation will communicate with the customer regarding the service that they expected and if it meets their requirements.
d) The DDM model is centred around integration between all sector departments and their goal of ensuring that South African citizens have access to basic services. Therefore, the Nordic will ask the questions WHAT and HOW; the GAP model will help management identify gaps they need to address to ensure quality services. SERVQUAL speaks to the dimensions used to measure the services being provided.
e) The literature also highlighted an increase in community unrest, a decline in the provision of essential services and a decrease in the trust that the communities have in the government. This speaks to all three models because it shows that the communities know what type of services they should get, how they should receive the services, the level of quality, and the fact that it should be consistent and reliable, which are all part of the five dimensions of the SERVQUAL model.

3.2 Proposed model and proposition

3.2.1 Root cause analysis

Root cause analysis was initially created in systems engineering to recognise "the essential and causal factor(s) that underlie variation in performance." [12]. In this paper it is used to derive the conceptual model in Figure 1 to be used in the research study.

Knowledge gained from the literature study forms the foundations for formulating propositions.

3.2.1.1 The local government needs to find out the number of South African citizens that have access to basic services.

Proposition 1: The South African Local government does not have a database indicating the number of households that have access to basic services.

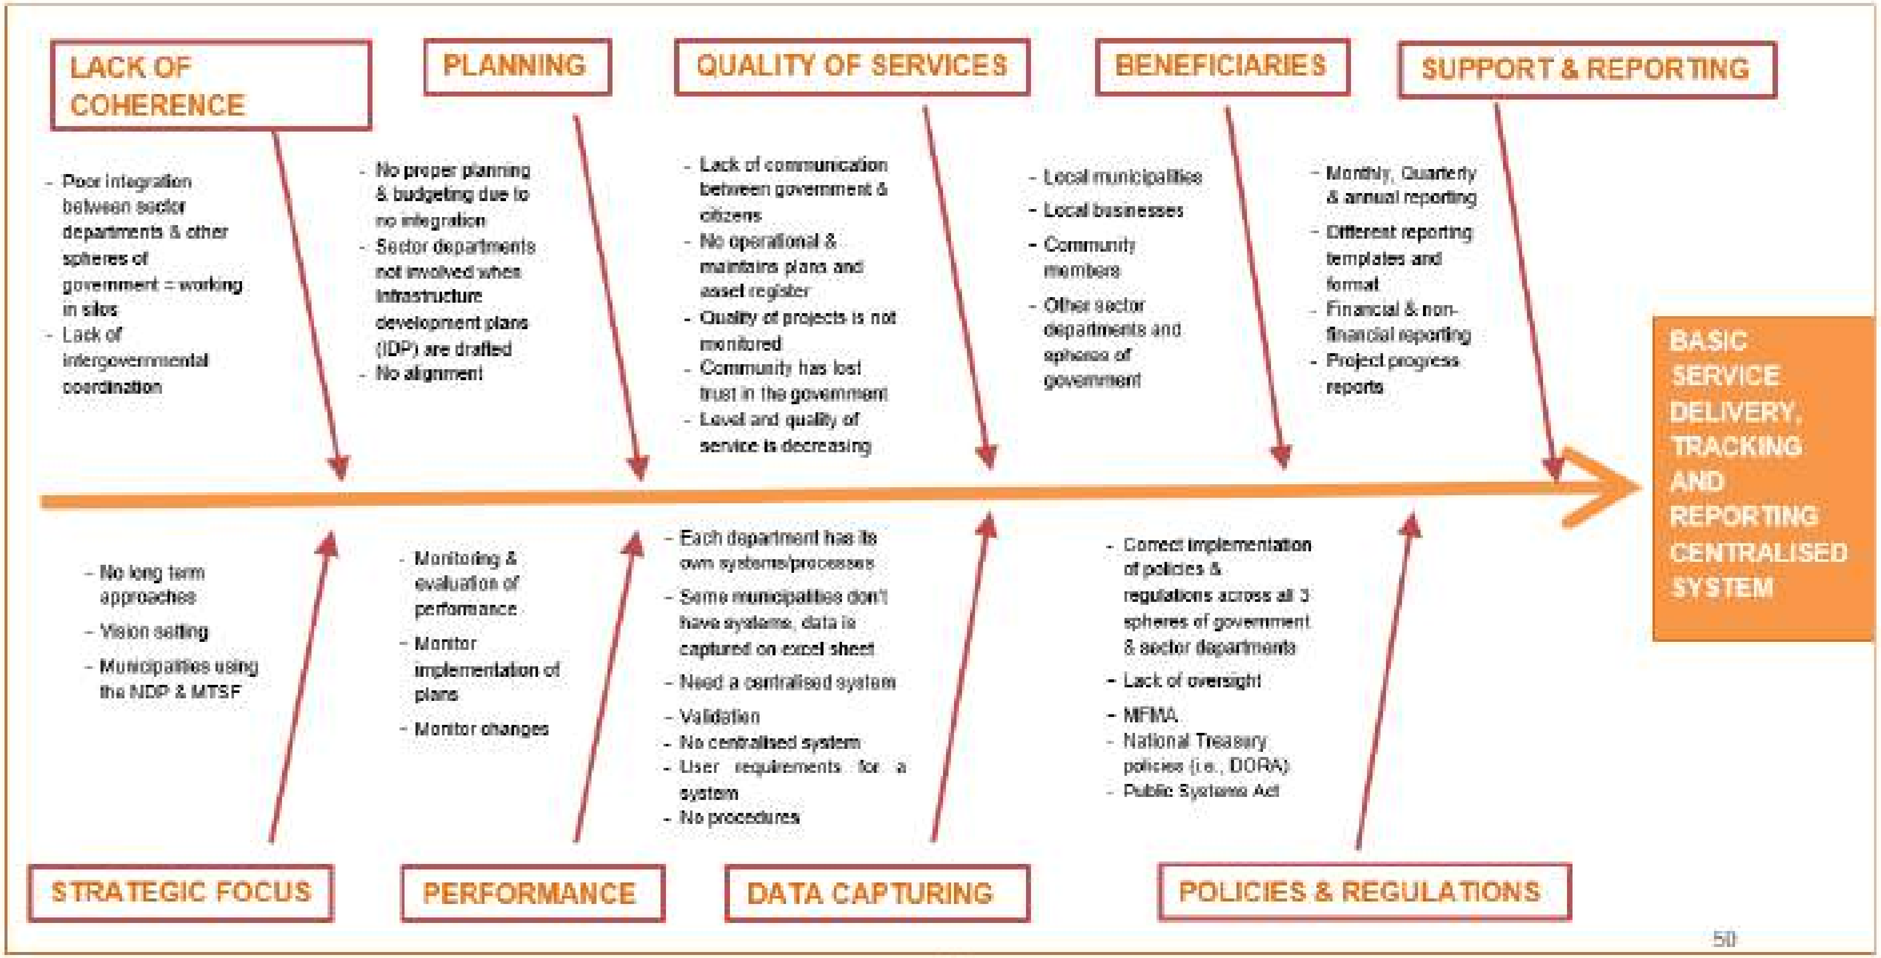

Figure 1: Concept model

3.2.1.2 Service delivery management tracking and reporting system

Proposition 2: The South African local government does not have a centralised basic service delivery tracking and reporting system.

3.2.1.3 Lack of integration between sector departments and other spheres of government affects service delivery.

Proposition 3: There is a lack of integration between sector departments and other spheres of government; they have their processes and systems, which impact the provision of basic services.

3.2.1.4 South African citizens have lost trust and confidence in the local government.

Proposition 4: South African citizens believe that government is not open and transparent when it comes to providing updates or feedback on the implementation of service delivery projects.

4 RESEARCH METHOD OR APPROACH

4.1 Research Design

Research designs organise research activity, including the collection of data, in ways that are most likely to achieve the research aims [13]. The research design will be based on a mixed method combining quantitative and qualitative methods.

4.1.1 Mixed Research

A mixed-method study involves collecting and analysing both the quantitative and qualitative data in a single study in which the data is collected concurrently or sequentially. The qualitative and quantitative information is integrated at the data analysis stage to answer the research questions [14]. The mixed method approach helps the researcher answer research questions that cannot be answered using the qualitative or qualitative methods in their own [14].

The mixed method has a list of purposes: triangulation, complementarily, development, initiation, and expansion. Triangulation was used for this study because it is used to support and corroborate the data results and the literature, as it will address the reliability and accuracy of the research [15].

4.2 Research Methodology

4.2.1 Qualitative Study

A qualitative study method is used to study a complex problem using various data sources and data collection methods. Triangulation strengthens the validity of the findings from qualitative research design by establishing converging lines of evidence. A study used for theory testing purposes is deductive, and the data results are used to validate the theory, modify it, or refine it based on the results from the study.

4.3 Sampling strategy

The sample for this research was taken from 257 South African municipalities. A non-probability sampling design is used for this research study because the sample size was based on accessibility to municipalities. The sample size is 130 municipalities with a confidence level of 90% **[16]**.

4.4 Data Collection

A questionnaire was used to collect data, the survey was done via software called Qualtrics, and a unique survey link was emailed to each Municipal Manager, their Assistant and Technical Directors. The responses to the survey were captured and stored on Qualtrics.

The close-ended questions stem from the research questions and the literature review. Questionnaires provide answers that are easy to tabulate and analyse. The questionaries are done via software therefore, the respondent's identity will be anonymous. Furthermore, questionnaires are a good way of collecting data because they are not expensive; they are more economical because one must only email the link to the respondent's [17].

The quantitative method will be the primary data, and the Qualitative method, which refers to reports and other literature, will be used as secondary data to validate the results and increase the research's accuracy.

4.5 Data Analysis

The data collected from the literature review that included the government reports will be integrated with the results from the survey to answer the research questions.

5 RESULTS

A unique survey link was generated for each participant to make it easier to track the number of municipalities that have responded. The unique link survey was sent to Municipal Manager, their Assistants, and the Technical Directors. A separate multiple-distribution survey link was created and sent to the municipality’s technical teams. The survey was conducted for a period of a month. Although the response rate from the survey is minimal (34) compared to the sample size of 130, the results will still be able to provide meaningful findings.

5.1 Proposition Evaluation

Proposition 1: The South African Local government does not have a database indicating the number of households that have access to basic services.

A municipality must have a database indicating the latest number of households that have access to basic services, as it is the foundation of the 5-year Integrated Development Plan (IDP) that municipalities draft and revise annually.

Table 1 indicates that 71% of the respondents (R) noted that their municipalities know the number of households that have access to basic services in their municipalities, and 100% of them agree that it is essential to know the actual numbers. The respondents answered additional questions to get a complete picture of how the data is captured, where it is stored and how the accuracy of the data is confirmed. Table 2 indicates that 67% of the respondents indicated that information is captured manually on a spreadsheet created internally, and 48% indicated that the municipality has a system that is used to capture the data.

The respondents were asked if their municipalities have a records management system or process; this question was asked to ascertain whether the municipality has a place where they store their information. Table 3 indicates that 50% of the respondents indicated that their municipalities have a records management system or process in place, 29% of the respondents indicated that their municipalities capture records by hand and store them in boxes, and 21% don’t have a system or process in place.

Table 1: Number of households with access to basic services

#	Do you currently know the number of households that have access to basic services (water, electricity, sanitation)?	Agree	R	Uncertain	R	Disagree	R
1	Yes (provide the numbers)	71%	15	60%	3	29%	2
2	No, I don't	29%	6	40%	2	71%	5
	Total	Total	21	Total	5	Total	7

Table 2: Current processes and system

#	How would you describe the current processes and systems that the municipal	Agree	R	Uncertain	R	Disagree	R	Total
1	There is no system/process in place	25%	5	30%	6	45%	9	20
2	The municipality captures data manually	67%	14	5%	1	29%	6	21
3	There is a system in place (please provide the name)	48%	10	19%	4	33%	7	21

Table 3: Records management system or process

#	Does the municipality currently have a records management system/process	Agree	R	Uncertain	R	Disagree	R
1	Electronic system	50%	14	33%	1	19%	4
2	Records are captured manually and stored in boxes	29%	8	33%	1	33%	7
3	There is no system/process	21%	6	33%	1	48%	10
	Total	Total	28	Total	3	Total	21

Table 4: Accuracy of data

#	How do you confirm the accuracy of the information that you have?	Agree	R	Uncertain	R	Disagree	R
1	We don't check the accuracy of the data	17%	6	50%	5	64%	9
2	We refer to the number of service delivery projects that have been completed	49%	17	20%	2	7%	1
3	Refer to government/sector department reports	34%	12	30%	3	29%	4
	Total	Total	35	Total	10	Total	14

The municipalities need to use accurate data for planning as this information will help the municipalities identify areas that they need to focus on interims of service delivery. Table 4 indicates that 49% of the respondents said their municipalities use the numbers from the service delivery projects that the municipality has completed; most of this information is generally captured on MIG-MIS, a DCOG system. 49% of the respondents indicated that they refer to sector department reports, and 17% indicated that they do not check the accuracy of the data.

The recent literature confirms that most municipalities know the number of households that have access to basic services; however, they are highly dependent on the information in the sector reports. The survey shows that 50% of respondents indicated that their municipalities have a database where the information is stored. The 34% depend on the numbers they get from sector department reports and the General Housing Survey data that StatsSA publishes. Therefore, P1 is false, that data is available however it is stored in different formats, and it is available on different sector department platforms.

Proposition 2: The South African local government does not have a centralised basic service delivery tracking and reporting system

The literature in chapter two highlighted the fact that local government needs a centralised system that tracks and reports on the provision of basic services in the municipalities. The municipalities report on the systems that the sector departments have developed. The municipalities use these systems to report on their expenditure, register projects and upload progress in order to ensure that departments such as COGTA and NT can monitor their expenditure.

Section 71(1) of the MFMA states that municipalities have to report monthly and quarterly; the survey indicated that 58% of the respondents said their municipalities report using templates, and 38% of the respondents said their municipalities utilise the sector department reports. 65% of the respondents indicated that they draft monthly progress reports on service delivery projects.

The results in table 5 indicate that 64% of the respondents said their municipalities utilise the sector department systems for reporting, and 23% of the respondents indicated that they don’t use any sector department systems. Municipalities were also asked if they currently have a records management system; over and above tracking and reporting, the municipalities need to have a POE for every single transaction and payment that is done. The results in table 6 indicate that only 50% of the respondents indicated that their municipalities have an electronic system.

Table 5: Utilisation of sector department systems

#	There are systems such as MIG-MIS, MIPMIS etc. Are these systems useful and can they be utilised for reporting on the number of households that have basic services?	Agree	R	Uncertain	R	Disagree	R
1	Yes	64%	14	31%	4	15%	3
2	No	14%	3	31%	4	45%	9
3	Municipality doesn't use any systems	23%	5	38%	5	40%	8
	Total	Total	22	Total	13	Total	20

Table 6: Records management system

#	**Does the municipality currently have a records management system/process?**	Agree	R	Uncertain	R	Disagree	R
1	Electronic system	50%	14	33%	1	19%	4
2	Records are captured manually and stored in boxes	29%	8	33%	1	33%	7
3	There is no system/process	21%	6	33%	1	48%	10
	Total	Total	28	Total	3	Total	21

The respondents that indicated that their municipalities do have an electronic system in place were also asked if the current system that they are using can track and report on the number of households that have access to basic services; 47% indicated that their systems can track and report and 37% of the respondents indicated that their municipalities have a system however it is outdated. As much as 64% of the respondents indicated that they use the sector departments for reporting, table 7 shows that 38% of the respondents said their municipalities have a system in place, but it has to be upgraded, and 35% are satisfied with the current system that the municipality is currently using, and 27% indicated that they need a new system.

Table 7: Satisfaction with the current system

#	**Are you satisfied with the system/processes that the municipality currently has in place to track and report on the number of households that have access to basic services?**	Agree	R	Uncertain	R	Disagree	R
1	Yes	35%	9	29%	4	46%	6
2	No, we need a new system	27%	7	29%	4	31%	4
3	The current system needs an upgrade	38%	10	43%	6	23%	3
	Total	Total	26	Total	14	Total	13

Municipal Systems Act states that the municipalities should have a performance management system in place for reporting, however it doesn't mention reporting on a centralised system. The result from the survey confirms that proposition 2 is true, the respective municipalities don't have a centralised system; this was confirmed by 64% of the respondents that indicated that they use the sector department systems for reporting.

Proposition 3: There is a lack of integration between sector departments and other spheres of government, they have their own processes and systems which have an impact on the provision of basic services

The problem of lack of integration between the three spheres of government was identified in the Presidency Budget Speech (2019). The speech stated that there is a "pattern of operating in silos", which impacts the planning and implementation of service delivery projects in municipalities.

The results from table 8 indicate that 42% of the respondents agree that sector departments and municipalities are indeed working in silos, and 16% indicated that there is no integration between the three spheres of government. Therefore, 58% of the respondents agree with proposition 3.

Table 8: Integration between three spheres of government

#	**Do you think there is integration between sector departments and the 3 spheres of government? or do you think they are working together?**	Agree	R	Uncertain	R	Disagree	R
1	Sector departments and the municipalities are working in silos	42%	8	33%	7	27%	3
2	No, there is no integration	16%	3	33%	7	36%	4
3	Yes, the sector departments and municipalities are working	42%	8	33%	7	36%	4
	Total	Total	19	Total	21	Total	11

The findings from the survey correlate with Chapter 13 of the National Development Plan which states the following [18]:

- The three spheres of government have struggled to achieve constructive relationships: and
- There needs to be more clarity around the separation of powers and functions, together with a lack of framework for the assignment of functions, which has created tensions between the three spheres of government.

Proposition 4: South African citizens believe that government is not open and transparent when it comes to providing updates or feedback on the implementation of service delivery projects

The Local Government: Municipal Structures Act 117 of 1998 states, "A municipal council must develop mechanisms to consult the community and community organisations in performing its functions and exercising its powers." The number of service delivery protests in South Africa has increased over the past few years due to the provision of poor basic services. The South African government system is weakened by the municipalities not being able to provide satisfactory basic services, and they are viewed as corrupt, as a result, the communities don't trust the government.

The municipalities were asked how they know whether the communities are satisfied/unhappy with the level and quality of services that they are receiving; table 9 indicates that 42% of respondents said they conducted interviews, and 39% said they received feedback from the council meetings.

The Municipal iQ recorded an increase in the number of protests for the period 2006-2021. The top three provinces were Gauteng at 24%, Eastern Cape at 16% and Western Cape at 15%. The Municipal IQ report also highlighted the types of demands that the protestors made; the following demands have been highlighted to support the proposition:

- Complaints about corruption in the municipality – 13%
- Complaints against the conduct of the councillors – 26%

Table 9: Feedback from communities

#	How does the municipality know whether the communities are satisfied/unhappy with the level and quality of services that they are receiving?	Agree	R	Uncertain	R	Disagree	R
1	Through interviews/feedback from the communities	42%	16	22%	2	10%	2
2	Through council meetings	39%	15	22%	2	10%	2
3	The municipality does not know	8%	3	11%	1	48%	10
4	Through the increase of community protests	11%	4	44%	4	33%	7
	Total	Total	38	Total	9	Total	21

5.2 Discussion of results

The discussion of the results will be based on the proposition evaluation and the research questions that were used to develop the proposition. The findings/results from the data analysis cannot be generalised because of the low response rate, therefore, the discussion will be centred around the responses from the respondents and the municipalities that they are from.

The findings from the survey highlighted that 71% of the respondents know the number of households that have access to basic services, and 50% of respondents indicated that their municipalities have a records management system in place where the data is saved. The fact that half of the respondents said that their municipalities don't have an electronic database is concerning. The utilisation of national department systems came out strongly, which confirms that the local municipalities do not have a centralised system. It also indicates that the municipalities are highly dependent on the information they receive from national and external sources, and they don't do their internal checks to ensure that the data they are using is correct and accurate.

Table 10: Centralised tracking and reporting system

#	Do you believe that a centralized tracking and reporting system would be beneficial to the municipality?	Agree	R	Uncertain	R	Disagree	R
1	Yes, it will be	73%	19	14%	1	0%	0
2	No, it will not	4%	1	14%	1	64%	9
3	Our current system is fine	23%	6	71%	5	36%	5
	Total	Total	26	Total	7	Total	14

The notion that the three spheres of government, specifically national and local government, are not working came out strongly; the fact that local government doesn't have a centralised system and instead does reporting on sector departments system is a concern, considering the fact that each system has its own intended purpose which most of them is centred around monitoring and evaluating the performance of the municipalities. The results in table 10 indicated that 73% of the respondents agreed that a centralised system would benefit their municipalities.

Table 11 in results indicated that 75% of the respondents said they want to change the current way that their municipalities are tracking and reporting on service delivery and 42% of the respondents would change the way data is collected and reported, 35% of the respondents said that the municipalities must develop a new service delivery tracking and reporting system, therefore the respondents agree that they need a centralised system that will be tailored for local municipalities.

Table 11: Current way of tracking and reporting

#	What or how would you change the current way that the municipality is tracking and reporting on service delivery?	Agree	R	Uncertain	R	Disagree	R
1	I would not change anything	23%	7	25%	3	75%	6
2	I would change the way the data is collected and reported on	42%	13	33%	4	13%	1
3	The municipality must develop a completely new service delivery tracking and reporting system	35%	11	42%	5	13%	1
	Total	Total	31	Total	12	Total	8

The results indicate that 100% of the respondents believe that the communities and the three spheres of government will benefit from the tracking and reporting system. The results also showed that 96% of respondents agree that it is essential to know the number of households that have access to basic services; these numbers are significant because the municipality has to use them for planning and drafting documents such as an Integrated Development Plan (IDP).

The survey results in table 12 indicate that the municipalities want the following requirements for the centralised system:

a. The development and implementation of a centralised web and mobile technology solution with capabilities and functionality for data capturing, external data source integration, analytics, and data analysis
b. A platform for capturing analysis and visualising data, and reporting
c. Aggregation of real-time (and/or batch processing) information on the status plans, projects, performance, and projections

A system cannot operate and be utilised for its intended purpose if the municipality doesn't have the infrastructure and human resources; the results in table 13 indicate that 34% of the respondents have access to Wi-Fi, 44% have access to laptops and computers, and they have 23% data capturers that have been trained. The results indicated that 60% of the respondents indicated that the project managers in their municipalities are the ones that do the reporting, tracking, and capturing of data on the provision of basic services. These results indicated that over 50% of respondents of the municipalities have the infrastructure and capacity required to operate and manage the tracking and reporting system. The results showed that the respondents believe that the communities, sector departments and other spheres of government would benefit from the system.

Table 12: Requirements for a centralised service delivery system

#	If a centralized service delivery tracking and reporting system were developed, what would your requirements be?	Agree	R	Uncertain	R	Disagree	R
1	Development and implementation of a centralised web and mobile technology solution with capabilities and functionality for data capturing, external data source integration, analytics, and data analysis	35%	15	40%	4	33%	1
2	Platform for capturing analysis and visualising data and reporting	33%	14	30%	3	0%	0
3	Aggregation of real time (and/or batch processing) information on the status plans, projects, performance, and projections	33%	14	30%	3	67%	2
	Total	Total	43	Total	10	Total	3

Table 13: Infrastructure and technical capacity

#	Does the municipality currently have the infrastructure and technical capacity to be able to utilize the tracking and reporting system?	Agree		Uncertain		Disagree	
1	WIFI	34%	14	22%	2	33%	4
2	Laptops and computers	44%	18	22%	2	25%	3
3	Data capturers/trained staff	22%	9	56%	5	42%	5
	Total	Total	41	Total	9	Total	12

6 CONCLUSIONS AND RECOMMENDATIONS

The analysis findings highlighted that the municipalities that were part of the study know the number of households that have access to basic services; however, they don’t do their internal check to ensure that the numbers are accurate. The consequence of not having a centralised tracking and reporting system is that local municipalities will lack adequate statistical information to make evidence-based decisions that will inform policy development, planning and budgeting. Due to the low response rate, one could not determine whether these findings apply to all 257 South African municipalities. The results confirm that The South African local government does not have a centralised tracking and reporting tool designed specifically for their needs; reporting is done on sector department systems, which can be confirmed through the District Development Model (DDM) literature.

The system through which the South African national and provincial governments have been monitoring the local government has not been as effective as one would have imagined. The absence of coordination and integration between the national government and the local municipalities has resulted in duplication and burdensome reporting obligations for municipalities. The current reporting system is mainly going up awards to the provinces and national departments; however, there needs to be reporting going downwards to the municipalities that need the information for their annual planning.

DCOG's mandate is to monitor the provision of free basic services in municipalities; therefore, a centralised tracking system would improve integration and coordination between the three spheres of government to ensure proper planning, proper allocation of resources and efficient implementation of basic services programmes that are at the desired level of economic and social impacts. The system will provide a platform where the local government can measure the impact it has made in providing basic services and has improved the quality of life of South African citizens.

A BUSINESS CASE FOR RECYCLING COMPUTER E-WASTE

N.S. Pillay[1*]
[1]Eskom Research Testing and Development
Johannesburg, South Africa
pillayna@eskom.co.za

ABSTRACT

The e-Waste Association of South Africa indicated that each South African generates 6.2 kilograms of e-waste annually with only 12% recycled, and the rest being refurbished and reused or ending up in disposal sites. e-Waste includes anything that requires electricity to function e.g., cellular phones, computers, printers, fridges, kettles, toasters etc. As of the 23rd August 2021, environmental regulation was passed that prohibits the disposal of all electrical and electronic waste to landfill in South Africa. In this study the feasibility of setting up a business case for an e-Waste recycling business was explored using system dynamics as a modelling methodology. The study considered the costs linked to the physical layout and business requirements to be economically feasible based on the annual throughput of the end-of-life computers. Based on a collection rate of 0.14 and a recycling rate of 0.12, simulation runs indicated that the approximately 24.65 Mtons of computer e-Waste would end up in landfill. Results also indicated that the biggest impact on obtaining a net profit for the business was inflation. Even with high volumes of laptops (51,975) and desktops (15,525), the business starts making a net loss after 13 years in operation.

Keywords: System dynamics, desktops, laptops, recycling.

1. INTRODUCTION

Electronic waste (e-waste) refers to end-of-life or discarded electrical and electronic equipment powered by electricity e.g., household appliances, office and communication equipment, lighting, tools etc. E-Waste is also referred to as waste electrical and electronic equipment (WEEE). Although e-waste has several toxic substances and materials which can be harmful to the environment and human health, it can also be a source of secondary raw material, thus reducing the need for primary material mining and related environmental impacts.

Global e-waste generation was estimated at 54 million metric tons in 2019, with China being the largest producer of this type of waste (more than 10 million metric tons in 2019), followed by the United States at 7 million metric tons [1]. Although there are no exact figures for South Africa, the Department of Environmental Affairs believes that e-waste is growing at a rate three times faster than any other form of waste while according to the e-Waste Association of South Africa, 6.2 kg of e-waste is generated per person with only 12% recycled [2]. A study in 2015 indicated that ICT and consumer electronics made up 79% of the total e-waste stream [3].

The National Environmental Management: Waste Act (Waste Act; Act 59 of 2008) was promulgated and effected since July 2009, to legislate waste management to regulate the waste industry. However, on the 23rd of August 2021, the National Norms and Standards for Disposal of Waste to Landfill was implemented, thus banning WEEE from being dumped in waste disposal sites [4]. This of course, compels industry to become more environmentally responsible and to find ways of reusing, refurbishing or recycling their WEEE.

In this study, the national landscape with respect to computer volumes was first calculated. Thereafter, laptop and desktop e-waste were selected to determine if there would be a business case for a company to set up its own recycling facility as part of their other product and services offerings, as opposed to paying an external recycling company for disposal and recycling. The possible number of Small to Medium Enterprises (SMEs) was calculated based on the national number of computers and the SME throughput. A system dynamics methodology was followed to build a simulation model in order to run scenarios.

2. METHODOLOGY

2.1 National Computer E-Waste

The first step was trying to estimate the number of computers that would be eligible for recycling. In doing this, the projection for population and for households was required by year 2050. A logistics equation was used to set a target based on historical information and on principles that all systems will tend to plateau at some stage because the physical constraints of systems are generally based on principles of classical, quantum or solid-state physics or thermodynamics.

In order to determine an estimate of the national number of computers in South Africa, three methods were used and the most plausible one chosen.

Method 1

The population in South Africa based on 2020 estimates was 61.04 million [5]. Based on the historical information, the target for 2050 was set at 75.50 million using a logistic S-curve equation. The population who are of working age (considered to be 15-64 years) is 39.09 million, and of the working age population, 38% are employed [6]. This value was then used to establish how many people in industry have computers and used in Eqn. 1. The high-level assumption was that all employed people have computers at work which is not accurate because some industries would not require employees to have computers e.g., cashiers, unskilled workers.

$$Computers_{commercial\ sector} = population \times working\ age\% \times employed\% \quad (1)$$

In order to calculate the number of people who have computers in the residential sector, the number of households until 2050 was calculated (with a goal setting target of 21.5 million by 2050). The fraction of households with a computer in Africa is estimated to be 7.7%, however in South Africa, this value is approximated at 21.5% [7] (refer to Eqn. 2).

$$Computers_{residential\ sector} = Households \times fraction\ with\ computers \quad (2)$$

The number of computers in the industrial sector was then added to the residential sector computers (Refer to Eqn. 3).

$$Computers_{SA} = Computers_{commercial\ sector} \times Computers_{residential\ sector} \quad (3)$$

Not all the computers in circulation are electronic waste so the total national number of computers was then multiplied by the fraction of e-Waste to consumed electronic goods (6.63/9.94 which was 0.67) [8].

Method 2

In the second method, the e-Waste per capita (6.2 kg/person) [9] was multiplied by the population. This was then divided by the average device mass (refer to Eqn. 4).

$$Computers_{SA} = (eWaste\ per\ capita \times population)/Computer\ Mass \quad (4)$$

Method 3

In this third method, it is estimated that there are 8.28 computers per 100 people in South Africa [10]. This value was then used to calculate the total number of computers based on the population (refer to Eqn. 5).

$$Computers_{SA} = Computers\ per\ capita \times population \quad (5)$$

The results for all three methods were compared and is shown in Figure 1. Methods 1 and 3 yield fairly similar results but Method 2 is by an order of magnitude higher. For purposes of this study, Method 1 was used, based on plausibility.

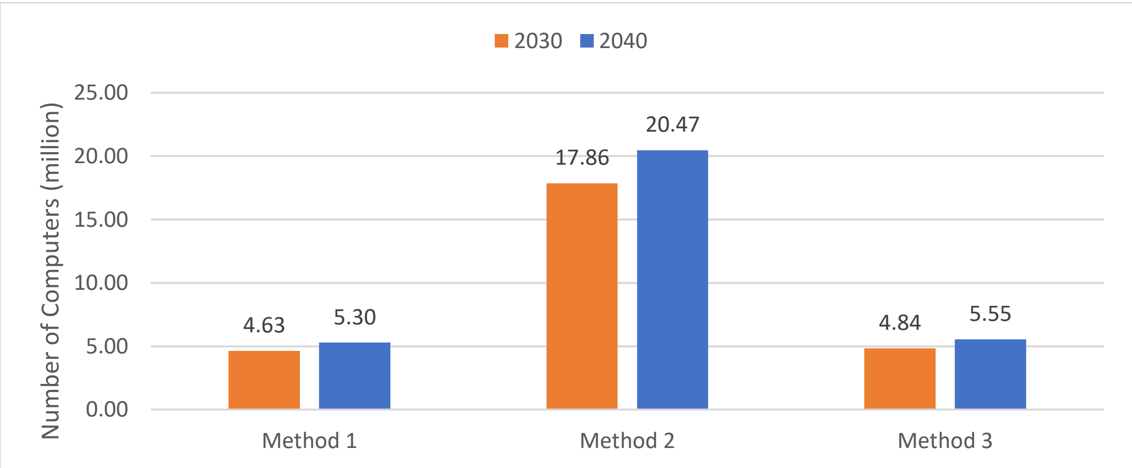

Figure 1: Comparison of different methods to estimate the number of computers in South Africa

After determining the possible number of computers in circulation, the number of computers collected was calculated based on an e-waste collection rate of 0.14 [11]. Of the computers collected, 12% were allocated to recycling [9], and 5% to refurbishment (there is no validated number that could be found through the literature review).

There is also a fraction of e-waste which is referred to as being “diverted from landfill” (25%) and included devices that are kept in storage or illegally disposed or exported [8]. This diverted value was excluded from the remaining uncollected computers sent to landfill sites.

2.2 SME computers

Computers were split into desktops and laptops due to the weight difference which would then impact the income sales calculations and the waste tonnages. Laptops weigh less than desktops so a fraction of 77% laptops was used and the rest allocated to desktops [12]. The base laptop mass was pinned at 2.2 kg [13] and desktop mass at 21.7 kg [14] – although the simulator does allow for these values to be adjusted.

The fractional masses of the various parts of the computer used are shown in Table 1 [15]. Desktop sales were also divided into a fraction (0.5) that would be sold as a batch of parts (tower, monitor, keyboard & the mouse) and the remaining fraction would be dismantled and discrete elements sold like the printed circuit board (PCB), plastics, cables etc.

Table 1: Fraction of total mass - computers [15]

FRACTION OF MASS	
	Value
Cable frac of computer mass	0.0197
plastic frac of computer mass	0.1521
PCB frac of computer mass	0.0275

The value of the sales in Rand per kg was based on the values shown in Table 2 for the PCB [16], plastics, cables, hard drive destruction [17] and lithium-ion battery (LIB). All of these values can be user defined and changed to run various scenarios.

Table 2: Price per unit - computers

ITEM R/UNIT	
	Value
Cables R/kg	10
Plastics R/kg	7
LIB R/unit	2
Hard drive destruction R per unit	20

Desktops that are dismantled have their tower, monitor, keyboard and mouse sold as a batch either locally or exported (again assuming that 50% of the throughput goes to the batch part sales department and the remaining are sent for recycling and refurbishment). If they are exported the sales prices are higher but then an exporters licence for the SME would be required.

The inflation rate used was an average of 7.8% [18] and annual sales increases was also kept at 7.8% to keep up with inflation. The average retail price for a desktop computer was taken as R28,000 [19]. The average retail price of a laptop was taken as R12,000 [20]. The takeback fraction could have been 0.1 based on a value quoted by Lenovo [21] or a fixed value for laptops (R500-R1000) and desktops (R500 – R750) older than 5 years [22]. The fraction as a function of the retail price was chosen, which allowed for a dynamic retail price.

In terms of the start-up costs: The business plan value selected was R8,000 [3], company registration was R750 [24], opening a bank account with a deposit was R5,000 with monthly fees of R85 [25], the facility setup and layout (to include a kitchen, eating area, ablution facilities) was taken to be R200,000 (verbal estimate from a building contractor); the registration fee for BBBEE was provisioned for in the structure but set at zero. The fee for the South African Chamber of Commerce and Industry (SACCI) was R135,150 [26]; for EWASA registration was R3,230 [27]; for a waste management licence was R3,965 using an inflation rate of 7.9% on the 2015 value [28]; for vendor registration with the government departments was R500 [29]; registration on the Provincial Waste Management System was R0 [30]. If exports were included in the simulator, it triggered a waste exporters licence cost of R2,450 [31]. ISO accreditation was also factored in at R17,000 [32].

In terms of the equipment required, the simulator allowed for the user to input the number of items required which was then multiplied by the unit cost per item. The lockable security cage was set at R6,884 [33]; the wire metal locker cage (2 tier) at R3,280 [33]; a pallet at R1,808; WEEE bin at R8,500; forklift at R50,000; a pallet jack at R3,967 [34]; pallets at R805 each [35]; a container trolley at R3,832 [36], 4 drawer steel cabinet for tools at R3,295 [37]; and a 3 ton forklift at R77,530 [8].

The start-up costs also assume a hard driver shredder for R204,128 [39]. A 20% deposit and 20% depreciation per year, as well as an interest rate of 12% and a payback period of 5 years was used. Other once-off start-up costs were allocated to purchasing a computer and printer (R55,129); software R25,000 [40]; security R25,000 [41]; insurance R756 [42]; and for the website R30,000 [43].

Additionally, training costs were included to ensure that the skills were appropriately equipped to handle the operations. With respect to this, costs were assigned for computer refurbishment training, Computer disassembly training and soft data and hard drive destruction.

If all of the above costs are factored in for start-up, the total required capital is R748,217.

Two calculations were carried out to determine the most cost-effective option in the long-term for the factory site. The first option was to rent the factory and property space and the second option was to buy the property. The area required for the factory was based on areas allocated to the offices, the workstations and factory. Other space considerations were for the tea and canteen area as well as the ablution facilities and the parking. The factory rental costs per square meter used was R85 [44].

Instead of rental, the other option would be to buy a property and pay it off over 15 years. Buying a factory of 943m^2 is approximately R4.3M [45]. Repayments (on purchase of the property) were calculated based on a 12% interest rate, a repayment period of 15 years and a once-off deposit of R500,000. A 1.6% bond registration cost and a 15% property transfer cost were also added which means that an upfront, once off total payment of R1,205,800 would be required.

The base scenario assumes a default of a manager, 1 administrator, 1 person for soft data and hard drive destruction, 1 floor & logistics supervisor, 1 cleaner, 1 security guard and 1 material handler. Depending on the number of computers that each dismantler can handle per day, the simulator then calculated the required number of dismantlers linked to the throughput. A similar process was followed to calculate the number of refurbishers.

Other annual operating expenditure costs included eWASA fees, insurance costs, telecommunications, property rates & taxes, and staff travel costs. Consumable costs such as for brooms, brushes, sanitizer, cleaning products, tea/coffee, toilet rolls etc. were also accounted for.

In terms of electricity costs, calculations assumed that the business operated 5 days a week for 8 hours a day. Electricity would then have been required for the following - Table 3. The initial electricity cost at the start of the SME business was R2,07/kWh [46] which would increase over a 10-year period to R4.07/kWh based on an annual inflation rate of 7.8%

Table 3: Costs linked to electricity consumption [47]

	kW	SME hrs/month	kWh/ month	kWh/ year
Desktop Computer	0,4	160	128	1,536
Monitor	0,02	160	3,2	38,4
Laptop	0,1	160	80	960
laser Printer	0,8	160	128	1,536
Internet router	0,015	160	2,4	28,8
Fluorescent light	0,015	720	162	1,944
Hard drive shredder	7,5	40	300	3,600
Kettle	1	40	80	960
Microwave oven	1,3	40	104	1,248
Coffee machine	0,8	40	64	768
Fridge	0,15	720	108	1,296
Other electricity (e.g., power tools)	0,5	160	2,400	28,800

It was difficult to get a good estimate for water costs. The average daily water used per day per person in South Africa is 237 litres in a residential area [48]. In trying to estimate the water used per person (toilets, drinking, coffee etc.), a value of 50 litres was used. It is a conservative value noting that a toilet flush uses 10 litres of water. This is one area that can be optimised by getting more accurate data from recycling companies.

In calculating the cost of transporting waste away from the site and transporting end-of-life equipment to site, it was assumed that a truck would be hired as and when required instead of employing a full-time truck driver which would add to the operating and capital expenditure costs. Depending on the volumes transported, costs were then calculated for a 3-ton truck or an 8-ton truck. The number of trips would depend on the number of computers being transported to the factory as a function of the throughput; and the volume of e-Waste away from the factory. Other assumptions used in calculating the transport costs was that an 8-ton truck would be used to bring in all of the computers and a 3-ton truck would be used to transport the waste away. The numbers of computers that could be carried in an 8-ton truck was approximated at 190 while the waste volume for 3-ton truck was 3 tons.

Recycling tool costs were factored in the simulation. Depending on the number of dismantlers and refurbishers, the model automatically calculated the number of tools and PPE required. The assumption on PPE as well as the refurbishment and recycling tools was that they would have to be replaced at certain periods or intervals (Table 4).

Table 4: Replacement periods

REPLACEMENT PERIODS	Value
SME Refurb tool replacement period yrs	5
PPE replacement period yrs	3
Safety Equip replacement period yr	3
Recycling tool replacement period yrs	6

Based on these costs and assumptions, various scenarios were run using a system dynamics simulator. The time frame of the simulator used an SME start-up year of 2022 and an operating period of 25 years. The engagement interface used to run the scenarios for the SME is shown in Figure 2.

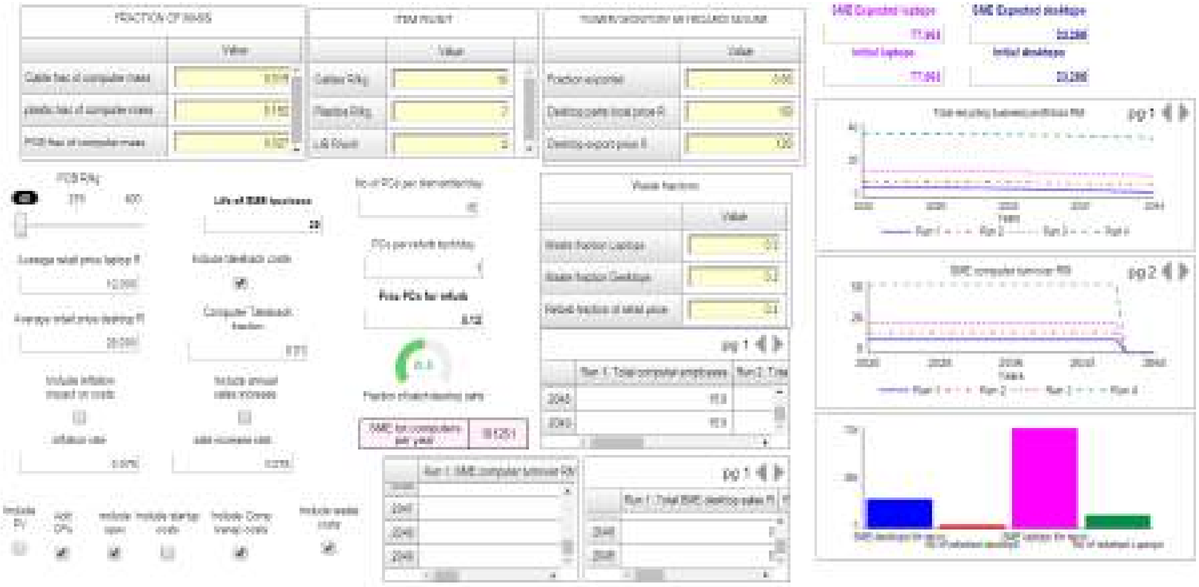

Figure 2: Engagement Interface for Scenario Runs

3. RESULTS AND DISCUSSION

3.1 National Computers

Based on the default parameters explained in Section 2, the base case for the results showing the volumes of computers in each category is reflected in Figure 3 for years 2022, 2030 and 2040. This included a collection rate of 0.14, a recycling fraction of 0.12, and a refurbishment fraction of 0.05. The “Diverted from landfill” refers to those computers that are not collected for recycling and refurbishment and are not in landfill sites either i.e., they are unlocated.

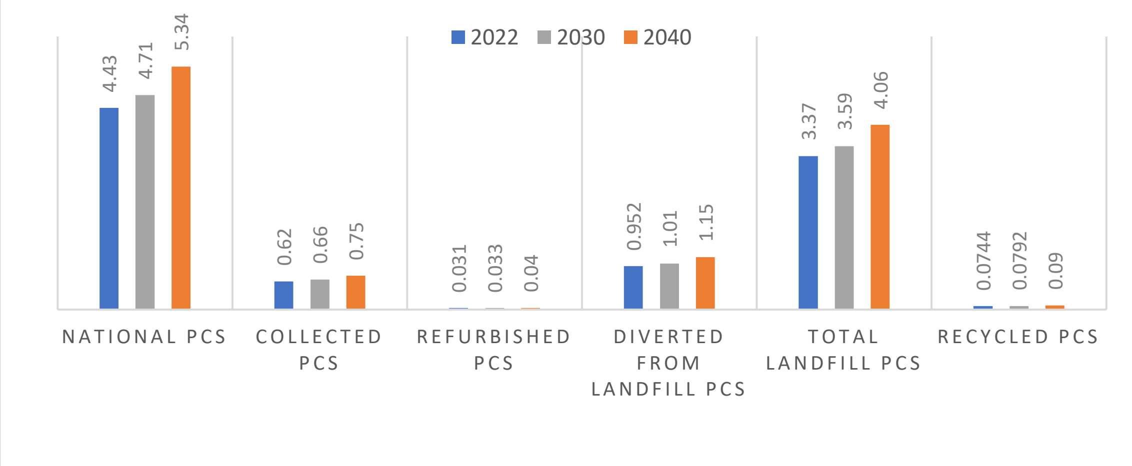

Figure 3: National Computers available and end-of-life categories in year 2040

The results show that there may be 5.34 mill computers in the country by 2040 and if the collection rates remain low and the reliance on landfill options is still high, only 0.09 mill computers would be recycled in year 2040. In terms of estimating what could currently be available, it would be about 4.43 million computers.

There are a lot more computers that would be diverted from the landfill in year 2040 (1.15 mill) and that are unaccounted for due to them being incorrectly disposed in illegal dumpsites or just kept in personal storage. If 5% of the computers are refurbished, this translates to 0.04 mill computers refurbished. The total number of computers going to landfill would be 4.06 mill.

The volume of landfilled computers and those that would likely be recycled based on the base recycling rates is shown in Figure 4.

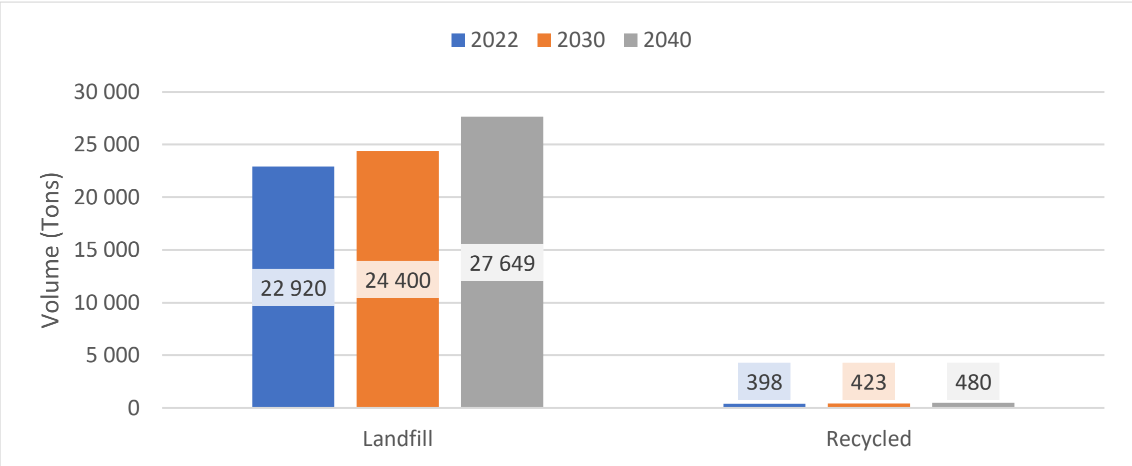

Figure 4: National Computer Tonnages

If collection rates remained at 0.14 and the recycling rate at 0.12, the expected volumes of computers ending up in landfill sites in year 2040 would have been 27,649 tons and the volume of computers that could be recycled would be 480 tons.

The collection rates for WEEE in the European Union measured in 2019 were 48.5%, with three member states achieving 65% [49]. If the collection rate (CR) was changed from 0.14 to 0.25 to 0.50, the impact on the recycled volume for computers was calculated for year 2040 and is shown in Figure 5.

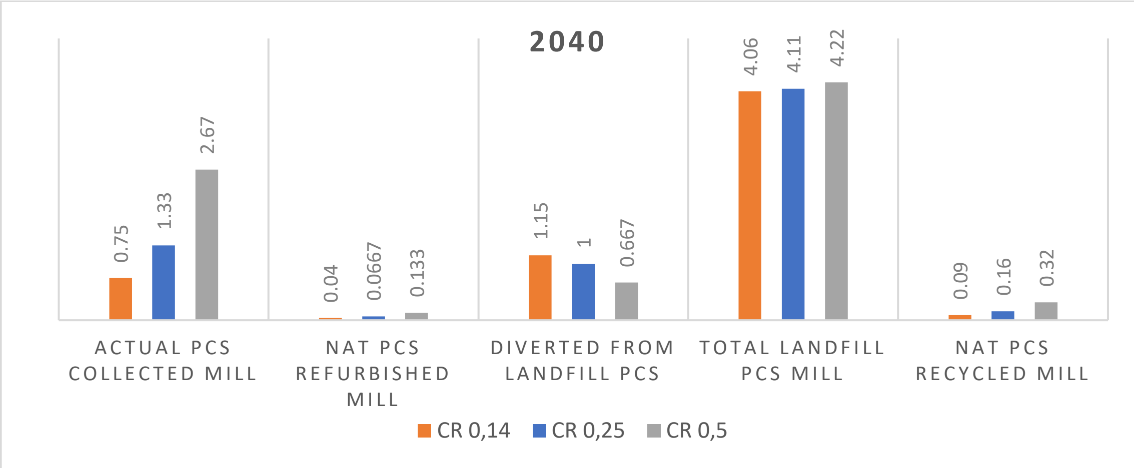

Figure 5: Comparison for different collection rates in 2040

As expected, as the collection rate increases (0.14; 0.25; 0.50), the number of recycled PCs increases and the number that would be refurbished. Additionally, since the collection rate increases, there is a smaller fraction of the uncollected that is expected to remain unaccounted for. The total number of computers at the landfill, however, gradually increases. The reason for this is a feedback loop that returns the computers that have been collected and not refurbished or recycled back to the landfill site. This value will thus increase as more computers are collected. It is also then added to the uncollected fraction that also ends up in landfill sites (decreasing trend).

The scenarios to compare the sensitivity of collection rate and recycling rate on recycled volumes is shown in Table 5.

Table 5: Impact of collection rate and recycling rate on recycled tonnages

	Collection rate	Recycling Rate
Scenario 1	0.14	0.12
Scenario 2	0.25	0.25
Scenario 3	0.50	0.50

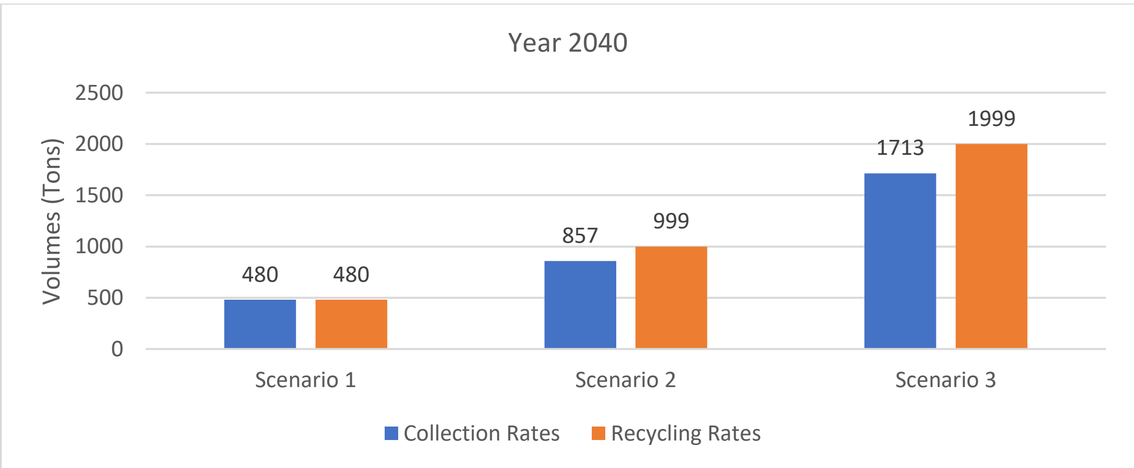

Figure 6: Comparison collection and recycling rates on recycled volumes

Results indicate that even though collection rates can increase, there must be a concerted effort at actively increasing the recycling rates in order to increase recycled computer tonnages.

3.2 SME Scenarios

Scenarios were also run to understand the impact on revenue based on various changing parameters shown in Table 6. For these scenarios, a base value of 15,400 laptops were used and 4,600 desktops with an average of 15 computers dismantled per day and 1 computer refurbished per day.

Table 6: SME Scenarios - Cost elements affecting SME Profit/loss

	Computer Sales	Operating & Capital Expenditure	Transport & Waste Costs	Computer Takeback	Inflation
Scenario 1	X				
Scenario 2	X	X			
Scenario 3	X	X	X		
Scenario 4	X	X	X	X	
Scenario 5	X	X	X	X	X

For each subsequent scenario, one additional parameter was added to determine the relative impact on profit/loss of the SME. Results are shown in Figure 7.

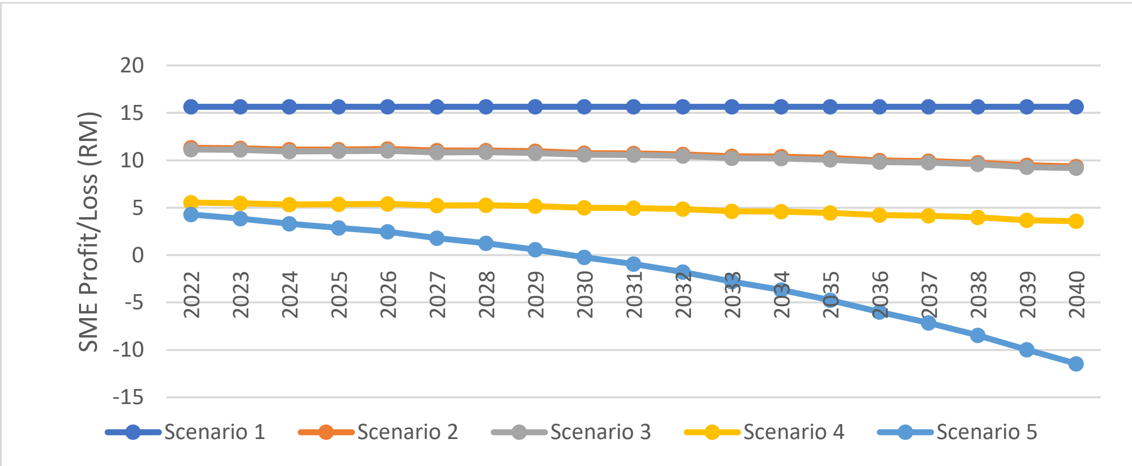

Figure 7: Comparison of various parameters on SME revenue

Scenario 1 disregards any costs and expenses for the SME and would mean an annual revenue of R15.6M. Scenario 2 considers all the operating expenses (dismantling & refurbishing tools, salaries, factory costs, utility bill etc) and capital expenditure which yields a revenue of approximately R11.3M in 2022 and R9.35M in year 2040. In 2022, Scenario 3 where waste costs (fraction of materials that cannot be reused or recycled) are factored in, has a revenue of R11.14M and R9.17M in year 2040.

A significant drop in revenue is if a computer takeback cost is factored (even at 1% of the retail price of the computers), as shown in Scenario 4, although still profitable at R5.53M in year 2022 and R3.57M in year 2040. If 7.8% annual inflationary increases are factored in then after 7 years, the SME will have to relook at strategies since they would be making significant financial losses from year 2030.

The next scenarios (Table 7) looked at changing the throughput of the computers considering all of the costs to find a breakeven point. Each scenario was increased by 50% of the preceding scenario.

Table 7: SME Scenarios - Changing the Computer Throughput

	Desktops	Laptops
Scenario 1	4,600	15,400
Scenario 2	6,900	23,100
Scenario 3	10,350	34,650
Scenario 4	15,525	51,975

The results in Figure 8 show the impact of changing throughputs (without inflation) and Figure 9 shows the impact on revenue with inflationary considerations. The assumption is that the sales prices does not increase at the same rate.

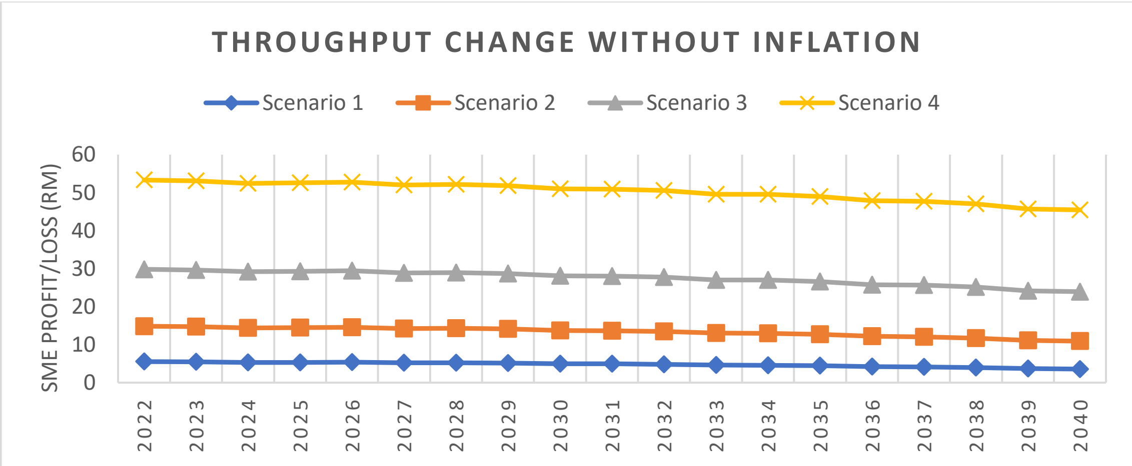

Figure 8: Comparison of various throughputs (without inflationary impacts)

Without considering inflation, the higher the throughput, the higher the profit for the SME with Scenario 4 yielding a 2022 profit of R23.48M and in year 2040, a profit of R21.52M. The least profitable is Scenario 1 but nonetheless profitable throughout the life of the SME.

Based on the results in Figure 8 and Figure 9, the impact of inflation is marked and even at the highest throughput of 15,525 desktops and 51,975 laptops (Scenario 4). The business would end up making losses for Scenario 1 in year 2030 and for Scenario 4 in year 2035.

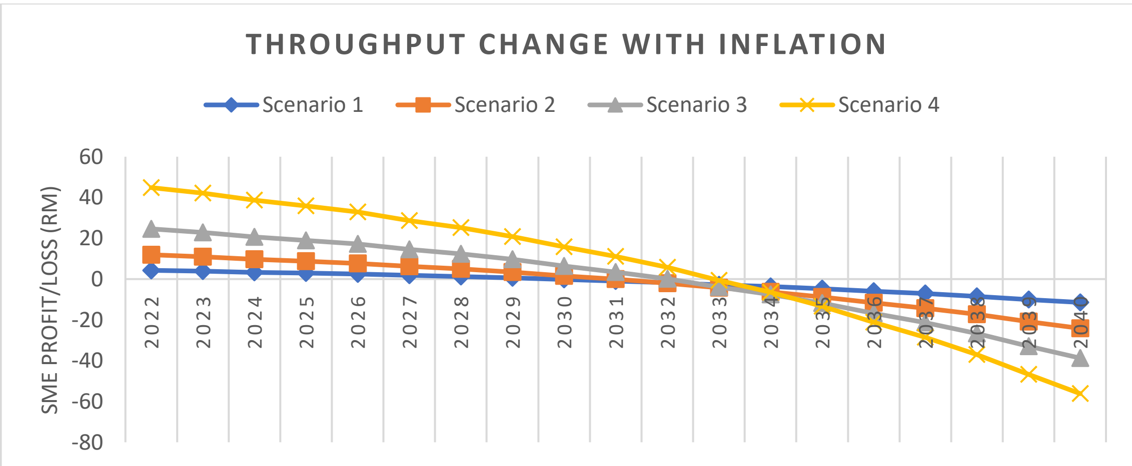

Figure 9: Comparison of various throughputs (with inflationary impacts)

It must be noted that as the throughput increases, so too does the number of dismantlers and refurbishers to be able to handle the volume which means a higher salary expenditure and dismantling & refurbishing equipment, personal protective equipment, utility costs etc.

The next Table 8 shows the number of SMEs that would be possible based on the national number of computers and the SME throughput of 4,600 desktops and 15,400 laptops.

Table 8: Possible number of SMEs

	SMEs
Scenario 1 (based on national collected volumes)	31
Scenario 2 (based on recycled volumes)	4

The results shown above are based on the low collection and recycling rates and would be much higher if the rates were increased for computers. There is also a significant difference in results by an order of magnitude depending on whether the collected volumes are used or whether only the fraction of recycled computers are used for the calculations.

4. CONCLUSIONS

It is likely that there will be 5.34 mill computers in the country by 2040 and if the collection rates remain low and the reliance on landfill options would remain high with only 0.09 mill computers recycled in year 2040 (a volume of 480 tons). The volume that would end up in landfill would be 27.65 Mtons. However, due to the changing legislature in August 2021 which prohibits the disposal of WEEE in landfill sites, recycling and refurbishment would have to increase significantly.

Increasing the collection rates would mean a higher volume of computers routed to recycling. Results indicated that increasing collection rates was not as impactful than if more recycling took place.

In the case of the SME, if all the operating expenses (dismantling & refurbishing tools, salaries, factory costs, utility bill etc), waste costs (fraction of materials that cannot be reused or recycled) and takeback costs are factored in, the business is able to generate a profit of R5.53M in year 2022 and R3.57M in year 2040. However, if a 7.8% annual inflationary is factored in then after 8 years, the SME will experience a revenue loss of R0.22M. This means that the SME would have to consider various business and operating strategies to mitigate the significant financial losses. Some of these strategies would include having more computers dismantled and refurbished per employee besides increasing the sales values of products sold. It could also include sourcing computers from businesses that do not expect a financial incentive in the form of a takeback cost.

Even if the annual throughput increases to 15,525 desktops and 51,975 laptops; the business would end up making losses after 13 years in operation with inflationary impacts. Electricity tariffs were increased at a 7.8% rate but based on the historical and expected electricity tariff hikes in South Africa, it is likely that the electricity costs will also add to an overall decrease in revenue so the current calculations are still too conservative. Together with throughput increases, so too does the number of dismantlers and refurbishers increase to be able to handle the volume which means a higher salary expenditure and dismantling & refurbishing equipment, personal protective gear, water costs etc.

There is also a marked difference in the number of SMEs that could be expected if calculations were based on national collection rates (31 SMEs) compared to recycling rates (4 SMEs).

System dynamics proved to be an excellent modelling method because it allowed various simulation runs and scenarios to test the sensitivity of various parameters, to optimise the business elements for the SME. It also allowed feedback loops to be included in the structure of the model.

5. RECOMMENDATIONS

It would be valuable to obtain data on the actual refurbishment rates of the national volumes of computers since value of 5% was assumed due to lack of information.

A national recycling strategy needs to be actively driven with requirements from every business to consider this in their business operating models.

Actual costs linked to training and skilling workers would have to be factored in. Provincial breakdowns of the end-of-life categories of computers will be useful in supporting strategies for recycling in the provinces.

6. ACKNOWLEDGEMENTS

The author would like to acknowledge Eskom Research, Testing & Development, specifically Ronel Clarke and Shanita Moodley for their inputs and discussions in concluding this study.

ABSTRACT

The construction operation is not an exception to the Fourth Industrial Revolution (4IR), which is expanding and challenging multiple sectors. There is currently limited evidence that 4IR technologies are being adopted in the construction industry, especially in the least developed countries. The objective of this research was to conduct an extensive literature review regarding how the Fourth Industrial Revolution contributed to better performance in the construction sector. This paper reviews the published literature on the Fourth Industrial Revolution in the construction industry ranging from 2013-2023. A systematic literature review methodology was used to conduct a search. The findings indicate that there is still a lack of study on the positive impacts of sector 4.0 in the context of the construction sector, particularly with regard to the effect on performance. The several PESTEL (political, economic, social, technical, environmental, and legal) concerns must be addressed by the construction industry.

Keywords: adoption, construction industry, fourth industrial revolution, technologies

* Corresponding Author

1 INTRODUCTION

One of the largest worldwide industries is construction, and the foundation it creates is the cornerstone of economic development and competitiveness. The construction industry's scope of work is diverse, ranging from residential, industrial, and commercial projects to infrastructure construction [1]. According to the World Economic Forum, the construction industry contributes 6% to the global GDP and more than 8% to the GDP of emerging countries [2].

The term "Industry 4.0" originated in Germany as a proposal for a new concept of German economic strategy based on modern technologies. The concept evolved to express the fourth industrial revolution, which is based on a variety of technologies such as cyber-physical systems (CPS), the Internet of Things (IoT), cloud computing, and mobile computing, among many others. The goal of Industrial Revolution (IR) 4.0 is to digitize industrial processes in order to create a flexible yet extensive production and service network. like the manufacturing industry, the construction industry's performance can be enhanced through IR 4.0 [3]. The adoption of IR 4.0 creates a space where all automated machinery is connected via technology improvements to function and transmit information without the assistance of people, increasing efficiency [4].

When used, it enhances product quality while reducing time to market and improving operational performance, so the advantages are evident. Despite the numerous advantages that other industries have to offer, the construction industry has been slow to adopt these ideas [5]. World Economic Forum [6] states that businesses will increase productivity, streamline their operations, and reduce costs by implementing innovations including 3D printing and scanning, enhanced building materials, augmented reality, autonomous equipment, and drones. Project and process management, as well as improvements to quality, health, and safety. The 4IR technologies have the potential to raise building quality, boost health and safety, work conditions, and sustainability, and increase construction productivity while reducing project delays [7].

2 BACKGROUND

2.1 Fourth Industry Revolution 4.0

The 4IR entails process automation and information sharing among physical systems, manufacturing technology, and people. The Internet of Things, cloud computing, cyber-physical systems, and cognitive computing are also included in this. In the future, learning algorithms-powered computer systems will be remotely connected to robotic devices. This means that these machines require relatively minimal assistance from human operators to understand and operate robotic machinery [8]. The 4IR is South Africa's best hope for reviving the country's ailing economy. More investment in the automation of the construction industry is the most important factor in boosting the economy [9].

2.2 Productivity

Levin and Cunningham [2] said labor productivity in the American construction industry has actually decreased over the last 40 years, and it has stayed steady for the last 50 years. Farmer [10] argues that the severely low productivity of the construction industry is a crucial problem, highlighting both the glaring disparity relative to other industries in absolute terms and how the gap has grown over time. The development of digitalization has made it possible to address construction difficulties in new ways. The design, development, and operation of the built environment are being transformed by the Internet of Things (IoT) and Building Information. Modeling (BIM) [11]. Utilizing these technological improvements offers the chance to boost productivity [12].

2.3 Project delays

Worldwide, delays are a common issue with construction projects. In terms of the experience of delays, global research established that over a period of three years, 25% of construction projects were completed within 10% of their scheduled completion dates [13]. Toor and Ogunlana [14] examined the viability of incorporating BIM into a project management framework to track the progress of the building. The existing way of tracking work on sites presents a problem in terms of reducing delays. They say that using BIM and progress monitoring software has increased efficiency on construction sites, mostly because it has made information more readily available.

2.4 The construction industry and 4IR

When compared to other sectors, the construction industry has not changed despite the challenges it faces and the effects of the industrial revolutions (1-3) in Figure 1. In contrast to other sectors, the construction industry was noted to have adopted technology more slowly during past industrial revolutions [15]. The fourth industrial revolution distinguishes between digitalization and digitization. Numerous sectors have seen their processes change as a result of digitization. Digital technology has the potential to completely transform the building sector. Therefore, the construction industry shouldn't adopt the same sluggish mindset as it did throughout the preceding industrial revolution. Other industries have embraced various technologies in the 4IR to bring about change and gain an advantage. The fourth industrial revolution (4IR) is technologically driven, less dependent on human intervention, and more dependent on connecting and interacting with machines [2].

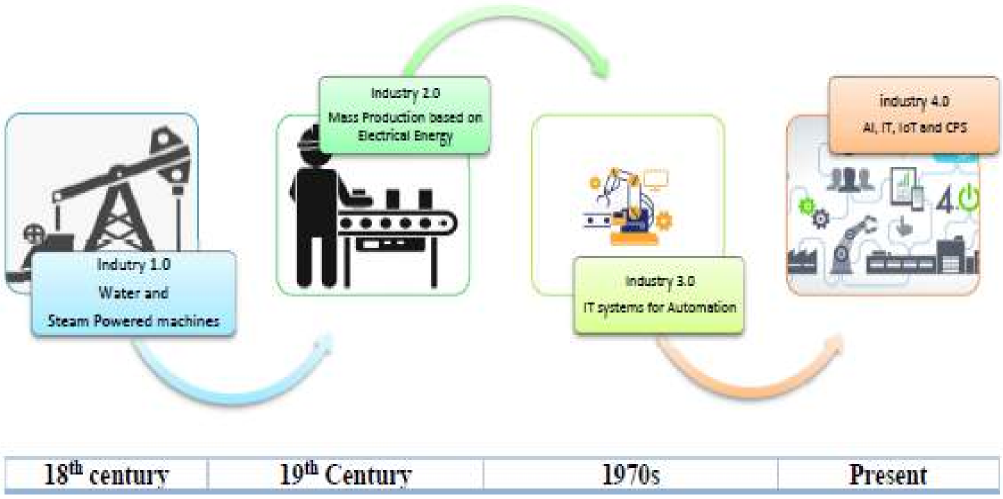

Figure 1:Industrial Revolution. Source: Adapted from[15]

In contrast to the previous industrial revolution, the fourth has a faster acceptance and change rate. In contrast to earlier industrial revolutions' experiences, the building industry seems to be catching up with technology more quickly. Another significant factor in the construction industry's quicker adoption of technologies is related to the coronavirus epidemic, in addition to meeting customer demands and obligations [16]. Researchers have recently introduced the phrase "construction 4.0" to describe the incorporation of Industry 4.0 into the construction industry. Few studies have looked at Industry 4.0 in construction, according to a survey of the literature. Then, a framework for construction 4.0 was provided in Figure 2 below [15].

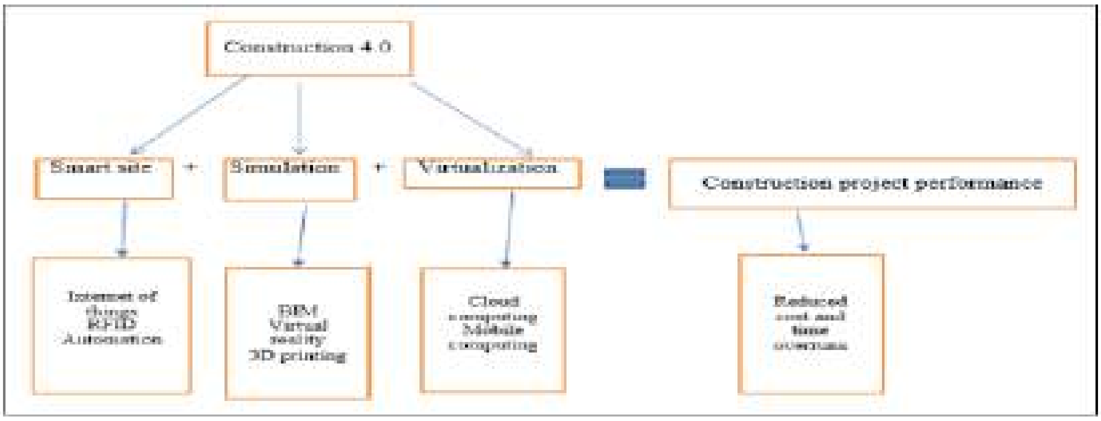

Figure 2: Construction 4.0 Conceptual Framework Source: Adapted from [17]

[18]were the first to introduce the phrase "Industry 4.0" to the literature in the construction industry. In an effort to assess the current research efforts in the fields of Industry 4.0 and construction, they conducted the study. It becomes evident that there are still no scientific papers in this field since their efforts are fruitless. Construction 4.0 research often concentrates on difficulties facing the construction sector, sector 4.0 preparedness, and applications of Industry 4.0 in construction [19]. However, certain researchers were intrigued by building 4.0's benefits and its role in improving performance. They stated that the adoption of Industry 4.0 technology in the construction sector will improve the efficiency of construction projects. The following studies have previously looked at the benefits of Industry 4.0 for the construction sector, [18] conducted a study to know how Industry 4.0 will affect the construction business. They discovered its potential advantages in terms of enhancements in productivity and quality using the PESTEL framework (political, economic, social, environmental, and legal), which they used to highlight the advantages of its adoption. Osunsanmi, Aigbavboa and Oke [15] state that the research was an assessment of the knowledge and preparedness of construction professionals for construction 4.0 and was conducted as part of research on sector 4.0 adoption within the construction sector in South Africa. The results showed that implementing Construction 4.0 would improve efficiency in terms of cost and time savings as well as the creation of sustainable buildings.

2.5 Construction 4.0 Technologies

A variety of technologies that are being used more widely as part of Industry 4.0 enable the implementation of the fundamentals of Construction 4.0. The following technologies will all appear in one or more ways in the engineering as well as construction industries[3].

- **Internet of Things (IoT) -** cooperation, shared decision-making, and object-to-object communication
- **Internet of Services -** a business model enabler for product as a service (PaaS). These may include smart equipment operating system software updates based on the real site conditions encountered
- **Internet of People -** People are a node in a dynamic information mesh, not merely a point source of data and information or a consumer of it
- **Simulation and Modeling -** promotes life-cycle design and design optimization
- **Augmented Reality (AR) -**Visualizing computer models and visuals in the real world
- **Virtual Reality (VR) -**enables the use of virtual objects as a platform for operations and maintenance (O&M) evaluations and construction

- **Big Data Analytics-**In order to find information such as buried patterns, correlations, trends, and preferences that aid in making educated decisions, big data analytics examines large data (that which contains greater diversity and arrives in growing volumes and with ever-higher velocity)
- **Cloud Computing -**Industry 4.0 is establishing data collaboration and sharing, although construction is still maturing

Figure 3: Construction 4.0 Technologies Source: Adapted from [3]

3 OBJECTIVES

The objective of the proposed study was to conduct a systematic literature review relating to the role of the 4th Industrial Revolution in enhancing performance within the construction industry. With the goal of focusing on the contribution of the 4th industrial revolution in the construction industry and shortfalls in the literature to enhance performance within the construction industry.

4 RESEARCH METHODOLOGY

The research methodology entailed the systematic review approach. A systematic literature review comprises a thorough examination of the literature on the subject at hand. Through literature review, the relevant literature is considered and analyzed, with the aim of finding possible research gaps [20]. The research gaps should be such that, if worked upon, they would help strengthen the field of study. According to [21] a structured literature review through an iterative cycle of defining suitable search keywords, searching the relevant literature, and performing the analysis at the end. In this paper, the authors adopted a similar review procedure.

To improve the analysis of the reviewed literature, the process began with the identification of the key ideas that related to the research objectives. The criteria included a generic review of the area under research, as well as limiting reviewed papers to those in English, and ensuring the relevance of the reviewed articles to the area under study. Data was then categorized and collected from the included studies in order to summarise and assess the results and characterize the characteristics of the role of the fourth industrial revolution in improving performance within the construction industry. In this work, a total of roughly 15 articles were identified. During the investigation, a well-defined and repeatable search strategy was adopted, and studies were either accepted or denied depending on the inclusion criteria. Due to the knowledge of the methodology's advantages and disadvantages, bias-free research controls were implemented.

4.1 Search strategy

General web searches conducted through the Google Scholar database have been utilized to evaluate and report on the contribution of 4IR to improving performance in the construction sector. The research methodology that was used was a combination of articles selection and procedures as shown in Figure 1 below. The following search term was used by the Google Scholar search engine: *4IR improving performance in construction industry*.

An initial search using the search string was conducted which yielded 85 articles. The researchers conducted a preliminary assessment based on reading the abstracts of all selected papers in order to concentrate on the most pertinent literature. According to Figure 4, this study starts with the initial collection as step number one of four steps. Collecting from search engine Google Scholar within the year from 2013 until 2023. A total of 15 articles were identified for the systematic review. The final articles to be included in this review were chosen by the authors using the probability sampling method, in which researchers randomly choose people from the population at predetermined intervals. A practical screening was done based on the inclusion criteria and flow diagram in Figure 4.

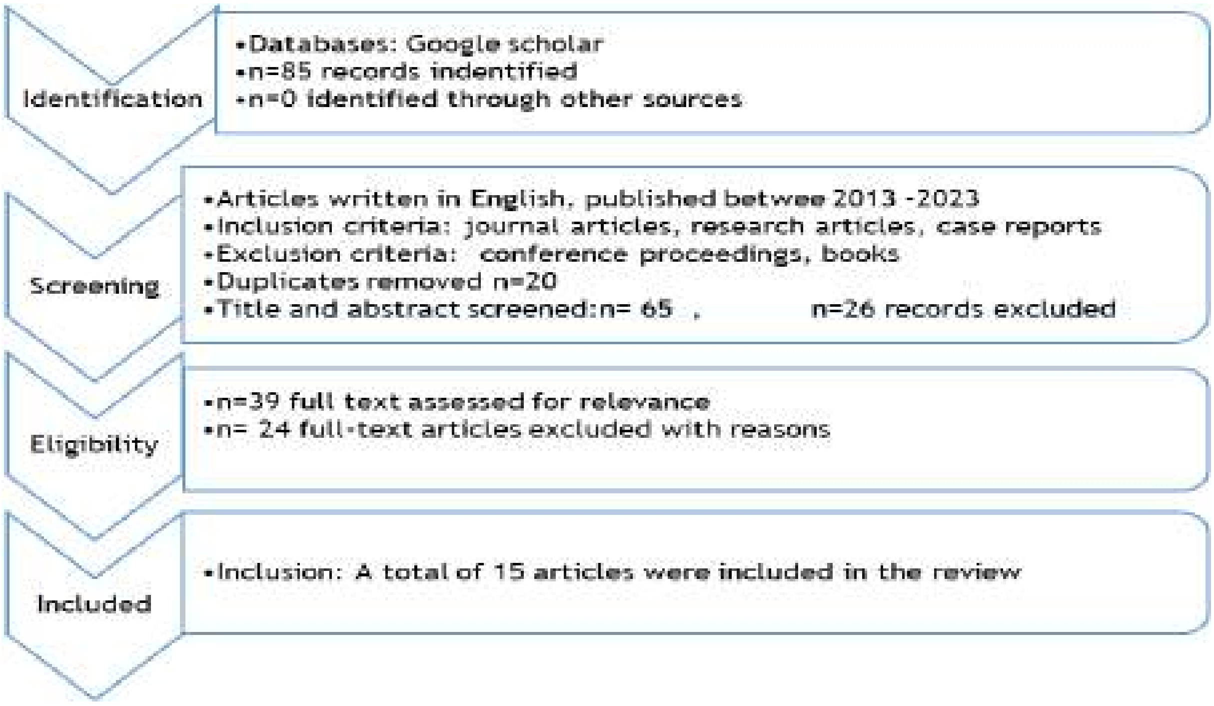

Figure 4: Systematic Review Flow Diagram. Source: Adapted from [20]

4.2 Inclusion criteria

On 3rd May 2023, a generic internet search produced 985 results for the first search. The first, tenth, twenty-first, thirty-first, forty-second, five hundred and fifty-fifth, seventy-eighth, and ninety-fifth websites were used as the basis for the sampling, and each of those pages had a maximum of ten articles. The 900 records were excluded as a representative sample was obtained. Systematic sampling provided the author with 85 studies. 85 studies were obtained by the author by systematic sampling. Additional information is provided in Figure 4 above regarding the screening and filtering that was conducted in accordance with the inclusion/exclusion criteria (Table 1). Studies that were released between 2013 and 2023 were considered. This includes 15 journal articles, research articles, and case reports. This procedure was followed to help the peer reviewers quickly determine the study's consistency in order to increase their confidence in the findings [20].

Table 1: Inclusion Criteria

Item	Description
Database searched	Google Scholar
Date of search	3rd May 2023
Language	English
Timespan	2013-2023
No.of records obtained	15
Search string	“4IR improving performance in the construction industry’’

Braun and Clarke [22]said that to find the pertinent themes, all of the articles that had met the standards were examined and coded using qualitative data analysis. The results of the 4IR improving performance in the construction industry have been listed in Table 2.

5 RESULTS

The researchers reported their findings related to the role of the 4th Industrial Revolution in enhancing performance within the construction industry. The findings of the literature research indicate that there is a growing body of knowledge on the subject of the role that the 4th Industrial Revolution had with regard to enhancing performance within the construction industry [23]. The studies shall characterize the studies by year of publication, industry sector, and type of publication.

5.1 Distribution of articles based on year of publication

The number of articles on 4IR in the construction industry published from 2013 to 2023 is presented in Figure 5. Although the absolute quantity of articles is small, it demonstrates an increasing trend, from 1 in 2013 to a maximum of 7 in 2021. This trend indicates the increasing amount of attention 4IR in the construction industry field received from researchers.

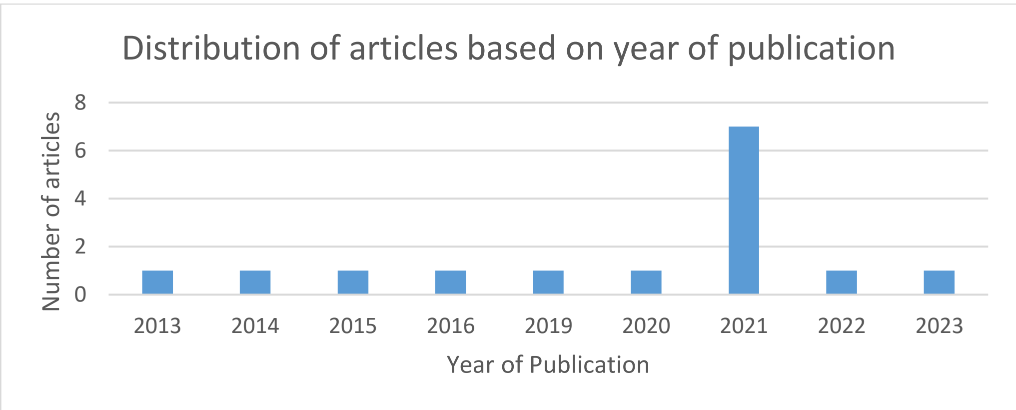

Figure 5: Articles based on year of publication

5.2 Distribution of articles based on industrial area of research

Among the papers looked at as per Figure 6, 6 research paper show Industry 4.0's implementations is mostly in manufacturing firms, 3 research paper shows Industry 4.0's implementations in supply chain management, and 2 papers show the application of Industry 4.0 in Supply chain sustainability. There is still a gap in terms of research done in other industries such as logistics and construction.

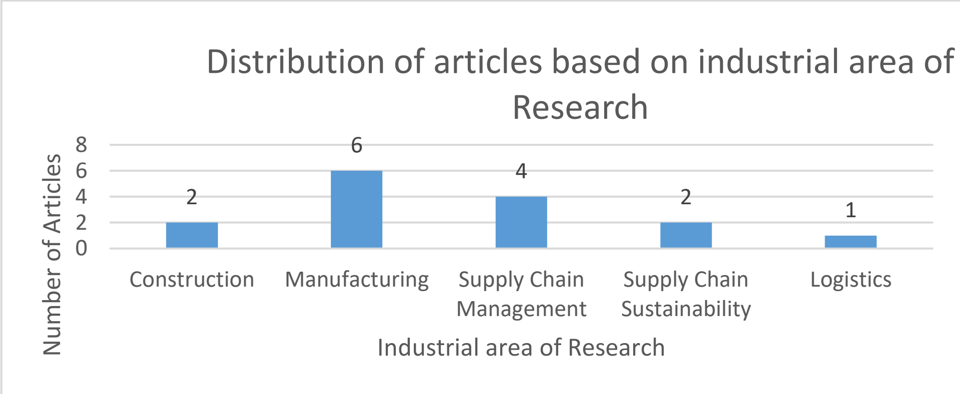

Figure 6: Distribution of articles based on the industrial area of research

5.3 Distribution of articles based on the Journal name

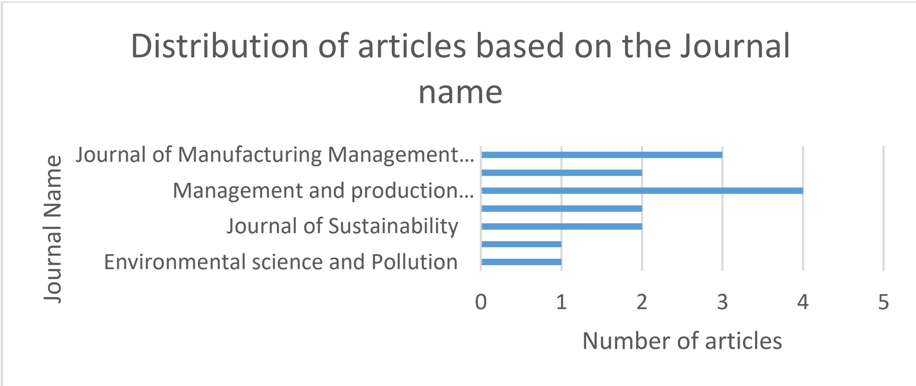

Figure 7:Distibution of articles based on the Journal name

Among the papers looked at as per Figure 7, the most journal that is publishing work on 4IR is Journal of Engineering and Applied Science, followed by the Journal of Manufacturing Management. There is still a gap in other journals as few articles are published there as compared to the Journal of Engineering and Applied Science.

6 DISCUSSION

Table 2 below provides a summary of the systematic literature review and learnings that are important for people in the construction industry regarding 4IR. Table 2 highlights what has been specified on the objective to say that indeed 4IR in the construction industry enhances performance as highlighted by the authors stipulated in Table 2 below.

6 CONCLUSION

The number of articles on 4IR in the construction industry indicated an upward trend between 2013- 2023 indicating the importance of 4IR in the construction industry by researchers. The majority of the studies that were reviewed were from Manufacturing, which indicated an interest in the Manufacturing sector.

A wide range of multidisciplinary technologies is included in the industry-specific definition of the Industry 4.0 concept for the construction sector to enable the digitization, automation, and integration of the construction process at all stages of the construction value chain. A few of the key ones include Building Information Modeling (BIM), Cloud Computing, and the Internet of Things. Industry 4.0 is a relatively recent area of research that is dominated by developed Western nations and is headed by Germany [23]. Although several disciplines are covered, the field of construction management stands out as being glaringly under-represented given that it is a globally major industry that employs millions of people and makes a considerable contribution to the GDP of individual countries as well as the global economy [2].

Their implementation can help to improve safety, sustainability, decision-making, and productivity in addition to the economic benefits for enhancing productivity, efficiency, quality, and collaboration, helping to improve the construction industry's negative reputation over time [24]. The adoption of sector 4.0 technology will have a significant impact on the whole construction sector, the companies involved, the environment, and workers. Construction industry performance would improve with the adoption of IR 4.0, enabling it to compete with its peers in the manufacturing and automotive industries. Industry 4.0 must be embraced since it is the direction of the future. Digitization is the only option, even on construction sites, construction must keep up [25]. Osunsanmi, Aigbavboa and Oke [15] said that implementing Construction 4.0 would improve efficiency in terms of cost and time savings as well as the creation of sustainable buildings.

7 FUTURE RESEARCH

Further research in science and practice is required to further the innovative idea of Industry 4.0 in the complicated context of the construction industry. Future work should address the challenges that were raised in terms of the adoption of 4IR in the construction industry.

ABSTRACT

As of recent times, Industrial Engineering has become one of the top ten scarce skills in South Africa. Given the versatility and resilience the field has, much of its success has contributed to its diversity of application. However, during the last few years there has been an increase in research within different niche areas that belong to Industrial Engineering. A larger question comes to mind, what are the current gaps (missing puzzle pieces) in this puzzle of research? This paper aims to investigate the SAJIE publications over the past five years, to unlock and evaluate the Industrial Engineering application domains. This research highlights the gaps in current literature, ergo emphasising opportunities for future research endeavours.

Keywords: Industrial Engineering, Knowledge domains, discussion paper, South Africa

[*] Corresponding Authors

1 INTRODUCTION

Industrial Engineering is a wide and deep field of study, which is known for its diversity in applications. Although there are varying definitions and explanations of Industrial engineering, one of the earliest comes from 1985, when the Institute of Industrial Engineers (IIE) defined it as [1, 2, 3]:

> *"Industrial Engineering is concerned with the design, improvement and installation of integrated systems of people, material, information, equipment and energy. It draws upon specialized knowledge and skill in the mathematical, physical and social sciences together with the principles and methods of engineering analysis and design to specify, predict and evaluate the results to be obtained from such systems."*

As of recent times, Industrial Engineering has become one of the top ten scarce skills in South Africa [4]. Industrial engineering is widely known for its creative problem solving via integrated solutions. Its range of applications may be broken down into different areas. Salvendy [2] explained this by breaking down Industrial and Systems Engineering (ISE) into four basic areas (operations research, human factors engineering, management systems and manufacturing systems engineering), with overlapping knowledge and application areas (statistics, psychology, economics, accounting and mathematics). Figure 1 depicts this relationship and composition of the domains of Industrial and Systems Engineering (ISE).

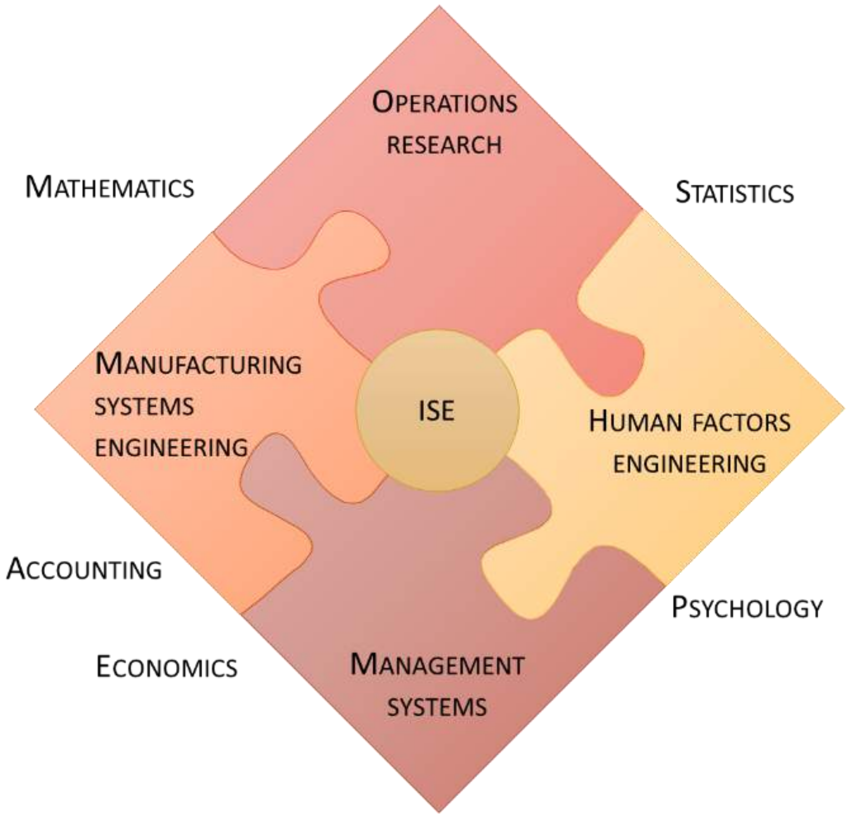

Figure 1: Domains of Industrial and Systems Engineering (ISE) (Adapted from Salvendy [2])

However, by 2022 the groups have been expanded upon by the Institute of Industrial and Systems Engineering (IISE) [5]. Ergo, according to IISE, there are 14 knowledge areas of Industrial and Systems Engineering. These 14 knowledge areas are captured in figure 2.

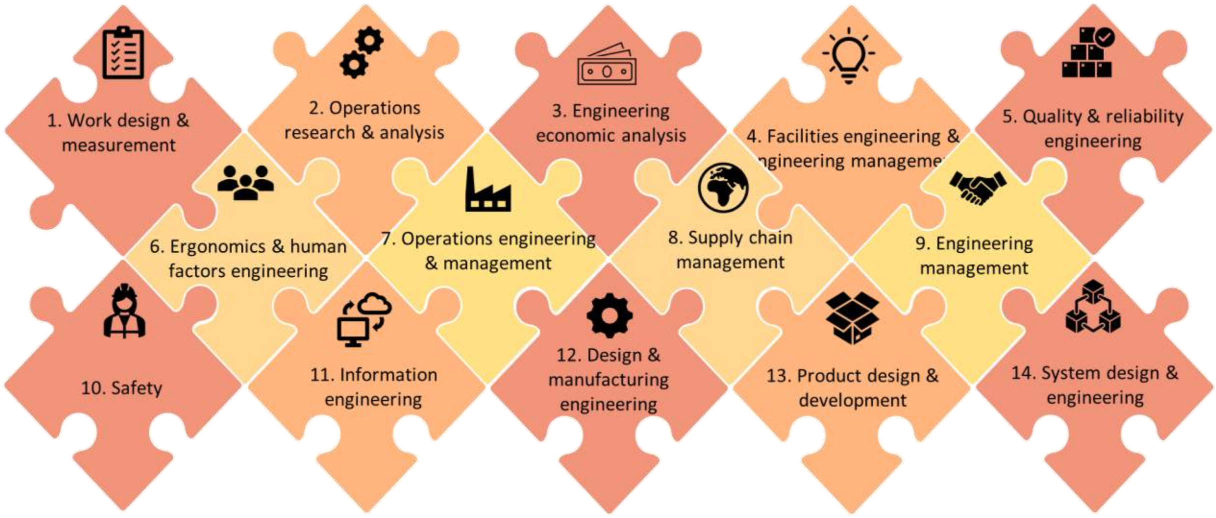

Figure 2: Knowledge areas of Industrial and systems engineering (Adapted from the institute of Industrial and systems engineering body of knowledge (IISE) [5])

From figures 1 and 2, it is evident that there are several complex building blocks to the Industrial Engineering skills and its understanding. The development of Industrial Engineering as an academic discipline in South Africa is relatively new, with the first group of industrial engineers graduating in 1964 (less than 50 years ago) [6, 4]. However, in the last 50 years the Industrial engineers have developed the field in South Africa at an exponential rate [7].

The South African Industrial Engineer is a complex person, not only do the embody the various knowledge areas and domains of Industrial engineering, but they also focus on several local issues in research and development. Darwish and van Dyk [8] focused on conceptualising the Industrial Engineering Identity. They found that there are eight levels to this identity, namely: Societal perceptions, external behaviours, skills and capabilities, knowledge fields, values, and motivators, thinking style, core belief, and fundamental belief [8]. These eight levels influence the research produced by Industrial engineering practitioners and academics [8].

As previously mentioned, Industrial engineering is inherently broad and interdisciplinary. A study in 2021 found that there are some misperceptions surrounding the disciple due to various job titles in practice [9]. The author explains that the true value of Industrial Engineering is found in the ability of IEs to improve concepts, processes, systems and/or industries; regardless of the job titles [9].

However, given the discussion above, during the last few years there has been an increase in research within the field of Industrial Engineering. A larger question comes to mind, what are the current gaps (missing puzzle pieces) in this puzzle of research?

2 RESEARCH AIM

This paper aims to investigate the South African Journal for Industrial Engineering (SAJIE) publications over the past five years (2018 – 2022), to unlock and evaluate the Industrial Engineering research areas.

3 RESEARCH QUESTIONS

The following research questions were set to achieve the research aim:

a) What are the most prominent domains of IE that feature in SAJIE over the past 5 years?
b) What are the most prominent Knowledge areas that feature in SAJIE over the past 5 years?

c) What are the most prominent countries of publication that feature in SAJIE over the past 5 years?
d) What is the gap/missing puzzle pieces in the puzzle of research?

4 RESEARCH METHODOLOGY

This study employs an adapted systematic review (SLR) methodology [10] to ensure research rigour throughout the study. The specific methodology consists out of the following three steps:

1. Planning - Develop a research protocol (Section 4.1)
2. Searching - Search the literature (Section 5.1)
3. Analysing - Data extraction and analysis (Section 5.2)

4.1 Step 1 – Planning - Develop research protocol.

It is imperative to note that while this study utilises an adapted SLR methodology, it is not by any means an SLR study itself; rather it is utilising a systematic review method to analyse the research output of the SAJIE journal over the last five years. Given the background, the research protocol was developed and is captured in table 1.

Table 1: Research Protocol table

Purpose of the study	To investigate the SAJIE publications over the past five years (2018 – 2022), to unlock and evaluate the Industrial Engineering application domains.
Inclusion criteria	All studies published in SAJIE
Database	South African Journal of Industrial Engineering (SAJIE)
Timeframe	2018 – 2022

5 FINDINGS

5.1 Searching - Search the literature.

The research protocol (table 1) was utilised to retrieve the past five years of articles from SAJIE. Table 2 encapsulates the totals of the search results per issue in each year.

Table 2: Results from literature search

Year	Volume	Issue	Number of articles
2018	Volume 29	Issue 1	15
		Issue 2	13
		Issue 3	21
		Issue 4	19
2019	Volume 30	Issue 1	12
		Issue 2	14
		Issue 3	21
		Issue 4	12
2020	Volume 31	Issue 1	13
		Issue 2	12
		Issue 3	22
		Issue 4	16
2021	Volume 32	Issue 1	16
		Issue 2	10
		Issue 3	27
		Issue 4	10
2022	Volume 33	Issue 1	14
		Issue 2	12
		Issue 3	26
		Issue 4	12
Total number of articles			**317**

5.2 Step 3 - Analysing - Data extraction and analysis.

After the retrieval of the articles captured in table 2, the full texts were read, and data was extracted and analysed. The following sections detail the analysis and answer the specific research questions.

5.2.1 What are the most prominent domains of IE that feature in SAJIE over the past 5 years?

The analysis begins with an evaluation and categorisation of the 317 articles subject to the domains of Industrial Engineering. Figure 3 demonstrates the number of occurrences per IE domain.

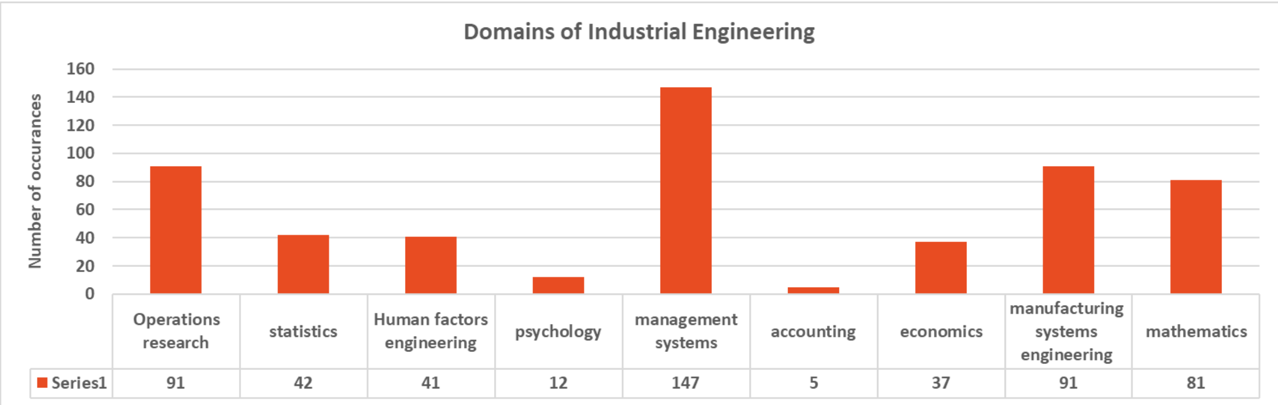

Figure 3: Bar graphic depicting the number of occurrences per domain of Industrial Engineering

Based on the results obtained in figure 3, a more detailed analysis was conducted on the number of publications per year for each IE domain. The results are depicted in figure 4.

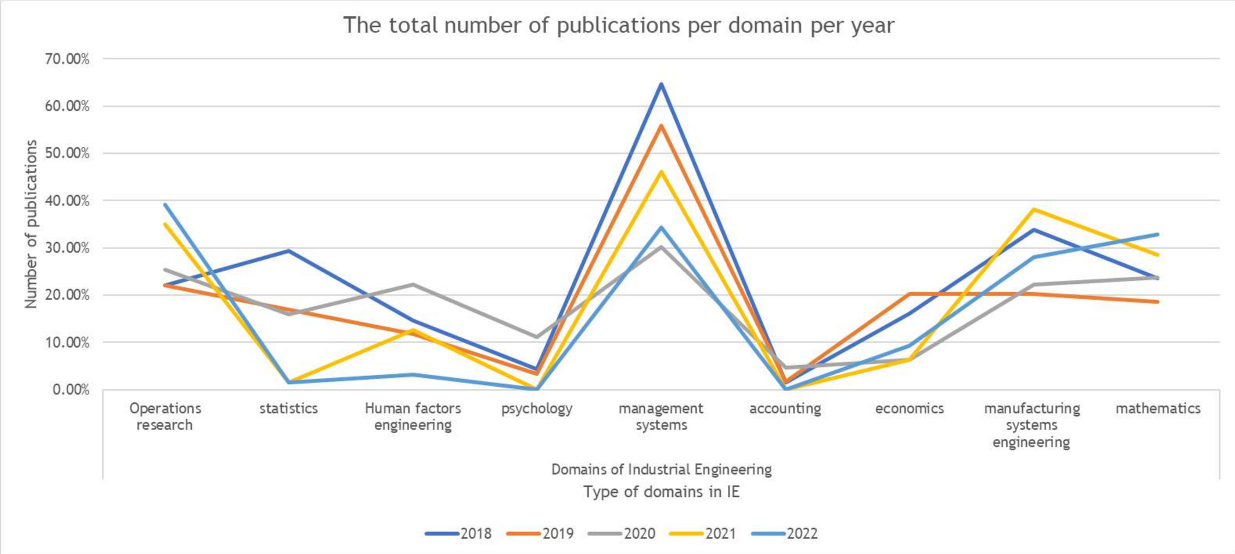

Figure 4: Number of publications per IE domain per year

A surge in publications is prevalent within management systems for each year. In 2018, more publications focused on statistics, manufacturing systems engineering and management systems. Economics orientated papers were more popular during 2019 while mathematics and operations research studies were at their lowest. By 2020, the distribution of publications is more balanced between each IE domain. It is also important to note in 2020, the journal had the highest publications for human factors engineering. Ironically enough, 2020-2022 saw a decline in management systems although the world was plagued with adjusting management systems to adhere to COVID-19 regulations.

In 2021, manufacturing systems engineering peaked in popularity. However, psychology and accounting studies were not featured. Operations research and mathematics constituted nearly 40% of the total publications in 2022. Between 2021 and 2022, there was a large decline in statistics and human factors engineering studies.

5.2.2 What are the most prominent Knowledge areas that feature in SAJIE over the past 5 years?

The analysis continues with an evaluation and categorisation of the 317 articles subject to the IISE bodies of knowledge. Figure 5 illustrates the total number of occurrences per body of knowledge.

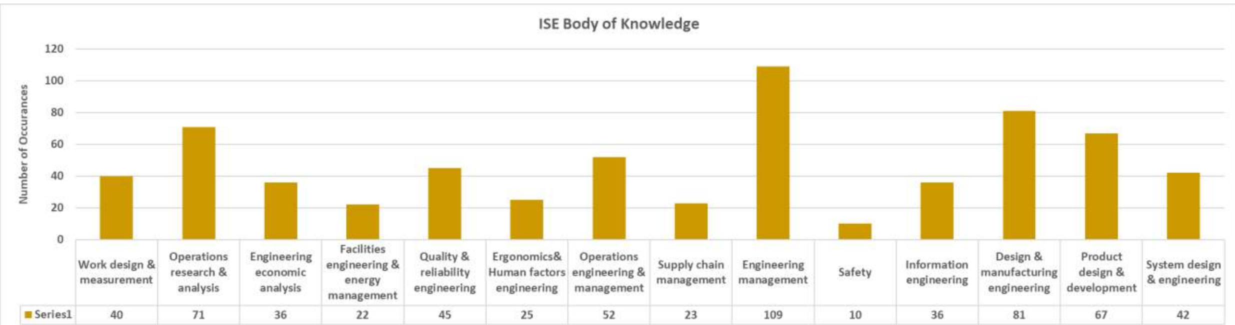

Figure 5: Bar graph depicting the number of occurrences per IISE body of knowledge.

Based on the results obtained in Figure 5, a further analysis was conducted on the number of publications per year for each industrial engineering body of knowledge. The results are depicted in figure 6.

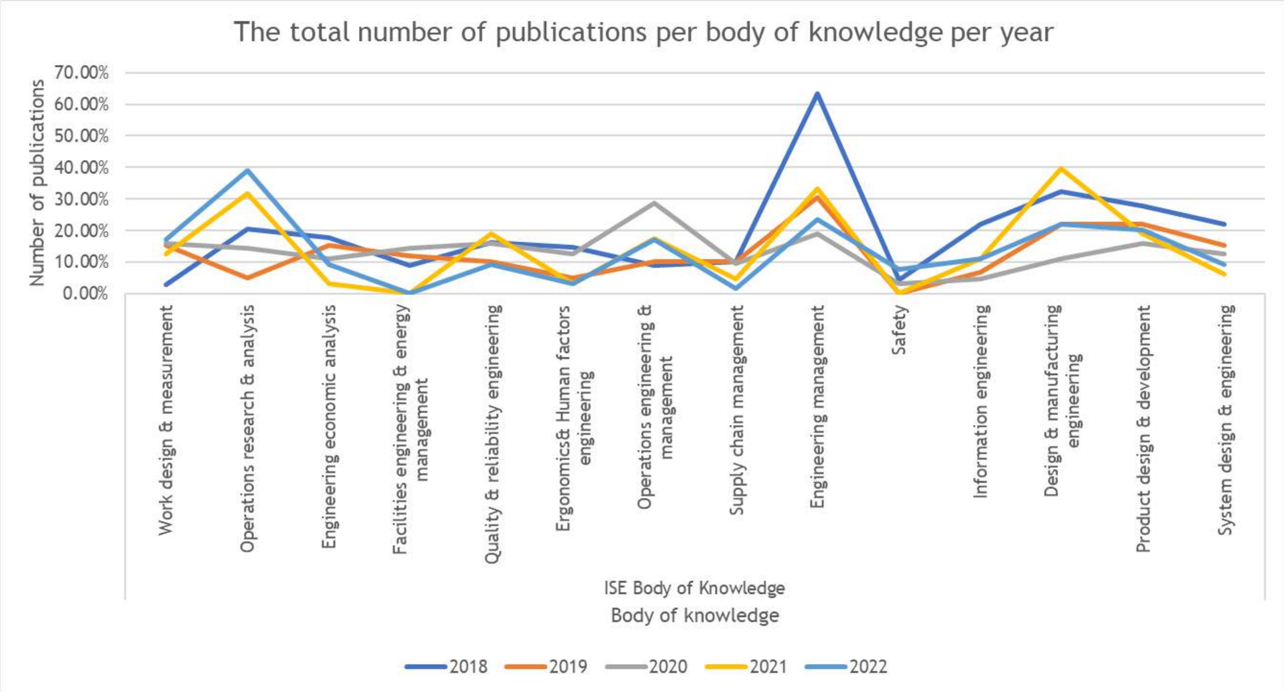

Figure 6: Total number of publications per body of knowledge per year

In a similar vein to the IE domains, engineering management was the most popular body of knowledge in 2018-2019. Generally, safety studies were the most under-researched body of knowledge. For 2018, work design and measurement were at the lowest while studies focusing on operations research, design and manufacturing engineering, systems design, information engineering and product design were at their highest. However, in 2019, operations research and analysis were least popular. As previously witnessed in figure 4, a more balanced distribution of studies is predominant for 2020. 2021 played host to a peak in design and manufacturing engineering whilst neglecting facilities engineering and energy management. Operations research and analysis was at its highest in 2022 while facilities engineering and energy management, supply chain management, quality and reliability engineering, and ergonomics and human factors engineering were lowest.

5.2.3 What are the most prominent countries of publication that feature in SAJIE over the past 5 years?

While SAJIE is a South African journal, it welcomes international publications. Figure 7 categorise the publications according to the most prominent countries over the past five years.

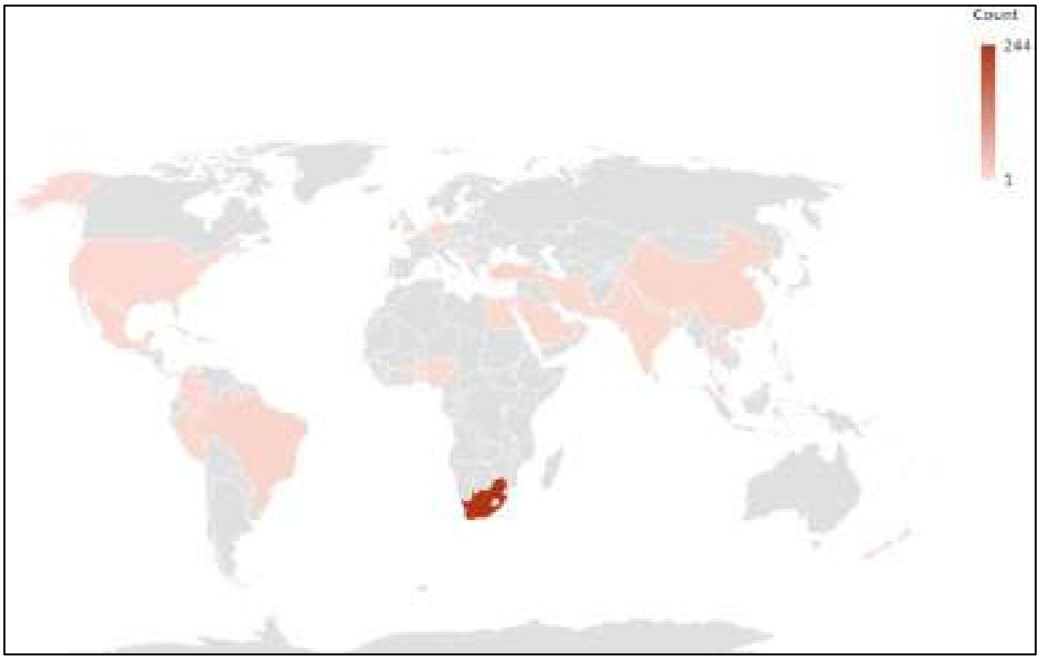

Figure 7: Global representation of author country of affiliation

Amongst these countries, 244 out of the 317 publications are located in South Africa. Brazil, China, and India were found to have the highest publications outside South Africa with nine, seven and six papers respectively. It could be argued that more studies within Africa could consider the journal for publication, to encourage the development of our neighbouring countries.

5.2.4 What is the gap/missing puzzle pieces in the puzzle of research?

The Southern African Conference of Industrial Engineering (SAIIE) is hosted each year in South Africa [11]. In 2022, it was hosted at Zimbali in Kwazulu-Natal and 2023 it will be hosted in the Western Cape. It is seen as a prestigious event where industrial engineers from all over the world are granted the opportunity to present their conference papers. However, during this event, a specific portion of the highest quality publications of conference papers is selected to be published in the special edition of SAJIE [11]. Subsequently, this is volume three of each year's publication in SAJIE. The theme of each conference from 2018 - 2022 is presented in figure 8.

Figure 8: Conference themes from 2018-2022 [11]

Figure 9 demonstrates the number of SAIIE's publications selected for the special edition each year, specifically focusing on each IE domain.

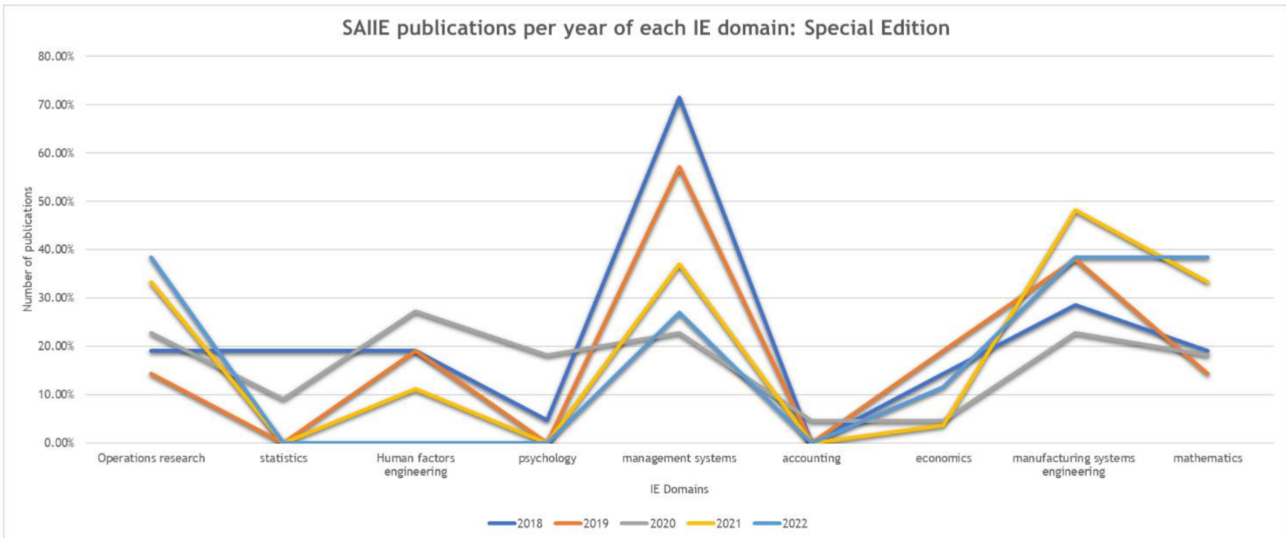

Figure 9: SAIIE publications per year of each IE domain: Special Edition

In 2018, the Fourth Industrial Revolution was the theme for the conference. We see a height in manufacturing systems engineering and management systems that is attributed to authors exploring the theme of the conference. 2019 embraced human factors engineering, management systems and manufacturing systems engineering as its most researched studies. The 2019 conference was aligned with alternative realities, real alternatives which ties in with the prominent domains highlighted in the graph. As for 2020, the data was more evenly distributed across each domain. This is indicative of the generalisation of the theme SAIIE "Green", as sustainability is non-biased to a specific domain.

Steps served as the 2021 conference theme, and it was found that the most prominent domains were manufacturing systems engineering, management systems and operations research. It is important to note that statistics, psychology and accounting had no representation during this year. Manufacturing systems engineering, operations research and mathematics were the most popular domains in the 2022 conference special edition. The theme for this conference was the Industrials which had a superhero flavour to it. This edition of the journal showcases the "superpowers" that Industrial engineers bring to the different domains. However, statistics, human factors engineering, psychology and accounting had no representation in this edition.

Figure 10 demonstrates the number of SAIIE's publications selected for the special edition each year, specifically focusing on the body of knowledge.

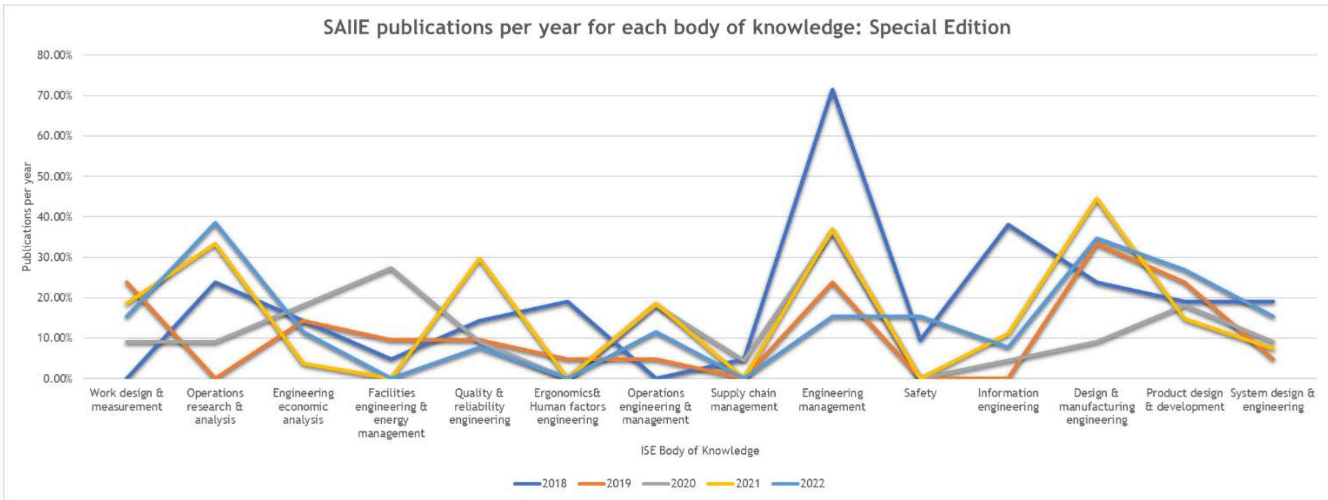

Figure 10: SAIIE publications per year for each body of Knowledge: Special edition

From figure 10, it can be deduced that engineering management is one of the foremost bodies of knowledge over the entire five-year time horizon. Design and manufacturing engineering closely follows with most of the studies over this period. This is indicative of the roots of Industrial engineering lying in the manufacturing industry. Operations research and analysis, and information engineering featured as the third highest bodies of knowledge. This pays homage to the growing research in Industrial engineering focused on introducing Industry 4.0 technologies and responding to the needs of a more data driven society that require the application of optimisation techniques. Unsuspectingly, supply chain management, facilities engineering, and energy management were the lowest bodies of knowledge over majority of the years, followed by safety. Given the political climate and energy crisis in South Africa, these topics are in dire need of more research focus going forward.

Co-occurrence tables

To better understand the relationship between the various domains of Industrial engineering, in terms of journal publications, a co-occurrence table was developed (Table 3).

Table 3: Co-occurrence table of the Domains of Industrial Engineering

Domains of Industrial Engineering	Operations research	statistics	Human factors engineering	psychology	management systems	accounting	economics	manufacturing systems engineering	mathematics
Operations research	91	25	1	0	11	0	7	22	64
statistics	25	42	0	0	14	0	7	10	19
Human factors engineering	1	0	41	10	19	0	1	7	2
psychology	0	0	10	12	3	0	0	0	0
management systems	11	14	19	3	147	1	16	27	16
accounting	0	0	0	0	1	5	4	0	1
economics	7	7	1	0	16	4	37	5	9
manufacturing systems engineering	22	10	7	0	27	0	5	91	23
mathematics	64	19	2	0	16	1	9	23	81

As can be seen from table 3, there exists a strong relationship between Operations research papers and statistics and mathematics articles. It is also worth noting that a large contribution of the operations research articles is based within the manufacturing systems engineering domains. The most integrated domain belongs to management systems, this is no surprise as this domain is all encompassing in nature.

Human factors engineering studies had close links with psychology and management systems. It is reasonable to assume that this is due their close links in theory as well. However, it is evident that little to no overlap exists amongst the rest of the domains. The accounting domain shares the weakest relationship with majority of the others. The only close link is that with economics. More research could explore operations research and statistics applications. Table 4 demonstrates the co-occurrence amongst the bodies of knowledge.

Table 4: Co-occurrence table of the ISE body of knowledge

ISE Body of Knowledge	Work design & measurement	Operations research & analysis	Engineering economic analysis	Facilities engineering & energy management	Quality & reliability engineering	Ergonomics& Human factors engineering	Operations engineering & management	Supply chain management	Engineering management	Safety	Information engineering	Design & manufacturing engineering	Product design & development	System design & engineering
Work design & measurement	40	9	1	2	5	3	11	2	8	2	4	7	8	2
Operations research & analysis	9	71	6	4	8	2	11	3	11	4	11	17	9	7
Engineering economic analysis	1	6	36	5	4	2	1	2	12	1	4	4	4	5
Facilities engineering &	2	4	5	22	3	1	1	2	7	1	2	0	1	2

ISE Body of Knowledge	Work design & measurement	Operations research & analysis	Engineering economic analysis	Facilities engineering & energy management	Quality & reliability engineering	Ergonomics& Human factors engineering	Operations engineering & management	Supply chain management	Engineering management	Safety	Information engineering	Design & manufacturing engineering	Product design & development	System design & engineering
energy maagement														
Quality & reliability engineering	5	8	4	3	45	3	10	1	12	4	3	12	8	3
Ergonomics& Human factors engineering	3	2	2	1	3	25	6	1	11	1	1	3	3	4
Operations engineering & management	11	11	1	1	10	6	52	4	19	0	5	11	8	7
Supply chain management	2	3	2	2	1	1	4	23	8	0	3	2	2	2
Engineering management	8	11	12	7	12	11	19	8	109	1	24	16	12	21
Safety	2	4	1	1	4	1	0	0	1	10	0	2	3	1
Information engineering	4	11	4	2	3	1	5	3	24	0	36	4	6	10
Design & manufacturing engineering	7	17	4	0	12	3	11	2	16	2	4	81	44	6
Product design & development	8	9	4	1	8	3	8	2	12	3	6	44	67	5
System design & engineering	2	7	5	2	3	4	7	2	21	1	10	6	5	42

From table 4, one can see a similar trend to that of table 3, with engineering management being the most dominant body of knowledge. In addition to this, it is also the most integrated body of knowledge due to its multidisciplinary applications. Design and manufacturing engineering is the next most integrated group. The gaps and opportunities in research are highlighted by the lack of papers in safety, facilities engineering and energy management, and supply chain management. These groups seem to function in silos. This presents an opportunity for future research as these bodies of knowledge have the potential to contribute greatly to the development of South Africa.

Table 5 illustrates the relationship between the bodies of knowledge and the domains of Industrial engineering. It is important to note that the domains of Industrial engineering encompass the breakdown of the bodies of knowledge.

Table 5: Co-occurrence table of ISE body of knowledge and the domains of industrial engineering

	ISE Body of Knowledge													
Domains of Industrial Engineering	Work design & measurement	Operations research & analysis	Engineering economic analysis	Facilities engineering & energy management	Quality & reliability engineering	Ergonomics& Human factors engineering	Operations engineering & management	Supply chain management	Engineering management	Safety	Information engineering	Design & manufacturing engineering	Product design & development	System design & engineering
Operations research	12	67	8	9	11	2	12	9	12	4	12	21	12	8
Statistics	4	18	9	4	4	1	7	5	14	1	6	10	6	7
Human factors engineering	6	1	2	3	8	18	9	3	17	3	2	5	7	7
Psychology	1	0	0	2	0	5	4	0	5	0	0	0	1	2
Management systems	19	12	14	8	23	17	30	12	96	3	25	25	23	30
Accounting	0	0	5	3	1	0	0	0	1	0	1	0	1	0
Economics	2	5	31	6	6	2	1	4	11	1	4	5	6	4
Manufacturing systems engineering	10	21	5	2	18	5	20	2	21	4	6	67	45	7
Mathematics	11	52	9	6	11	1	10	6	13	3	12	20	18	8

From Table 5, there are obvious relationships between the same topics such as operations research (domain) and operations research and analysis (body of knowledge); similarly with management systems (domain) and engineering management (body of knowledge). A counterintuitive relationship presents an opportunity to leverage operations research techniques in the facilities engineering and energy management space. More research is needed in the safety body of knowledge, this can integrate with almost every domain of Industrial Engineering.

To further evaluate the relationship between the Industrial Engineering domains and Body of Knowledge, table 6 outlines the difference in percentage of studies conducted in South Africa and other countries in terms of the Industrial Engineering domains.

Table 6: Industrial Engineering Domain comparison between South Africa and other countries

Domains of Industrial Engineering	South Africa	Other countries (avg)
Operations research	15,1%	23,6%
Statistics	6,7%	11,4%

Domains of Industrial Engineering	South Africa	Other countries (avg)
Human factors engineering	7,8%	5,7%
Psychology	2,5%	0,8%
Management systems	28,7%	20,3%
Accounting	0,7%	1,6%
Economics	6,7%	8,1%
Manufacturing systems engineering	17,7%	12,2%
Mathematics	14,2%	16,3%

Similarly, majority of the research tackles management systems in South Africa and other parts of the world. However, South African work then focuses more on manufacturing systems and mathematics, while other countries speak to operations research and mathematics. For example, publications from Turkey are found to have the highest proportion focused on operations research [12, 13, 14, 15, 16, 17]. Research addressing accounting is limited in South Africa, while psychology orientated work was found to be the least in other countries. This is indicative of the opportunities available for local researchers and practitioners to explore collaborations with international scholars on the aforementioned topics.

Table 7 provides the difference in percentage of local and international studies focused on the Industrial Engineering bodies of knowledge.

Table 7: Industrial Engineering Bodies of Knowledge comparison between South Africa and other countries

ISE Body of Knowledge	South Africa	Other countries (avg)
Work design & measurement	6,1%	6,8%
Operations research & analysis	10,4%	12,3%
Engineering economic analysis	5,7%	4,8%
Facilities engineering & energy management	3,0%	5,5%
Quality & reliability engineering	6,6%	8,9%
Ergonomics& Human factors engineering	3,8%	3,4%
Operations engineering & management	7,6%	8,2%
Supply chain management	3,0%	5,5%
Engineering management	18,0%	10,3%
Safety	1,7%	0,7%
Information engineering	5,7%	4,1%
Design & manufacturing engineering	12,3%	11,6%
Product design & development	9,7%	11,6%
System design & engineering	6,4%	6,2%

As can be seen from table 7, the highest proportion of engineering management is reaffirmed. The most under-researched knowledge area is found to be safety. Research from China was found to have the highest proportion of product design and development knowledge as opposed to other countries. Facilities engineering and energy management was the most popular knowledge area for publications from Iran. This presents the opportunity for local authors to leverage international collaborations with their counterparts on the aforementioned areas. For instance, supply chain management, facilities engineering and energy management, engineering management, operations research and analysis, and product design research can be supported by other international scholars. Conversely, South African researchers can offer support to international counterparts in their respective research fields.

Word cloud

The titles of each of the 317 studies were imported into a software to generate a word cloud (figure 11), which highlights the most recursive terms used by authors.

Figure 11: Word cloud of the most frequent words within the titles of articles

Unsurprisingly, figure 11 showcases the words management and industry as the most used terms. This talks to management engineering the most popular domain and body of knowledge. The terms performance, manufacturing, framework, model, development, implementation, systems and analysis were moderately popular. This is testament to the various conceptual solutions that are implemented (primarily in manufacturing contexts) to assess performance in an organisation.

6 CONCLUSIONS AND RECOMMENDATIONS

This study demonstrated the innovative research presented in SAJIE over the past five years. Furthermore, it emphasises the contribution SAJIE has made to the Industrial Engineering community globally. While this paper showcases the gaps (missing puzzle pieces) in certain research areas, it is imperative that this is seen as valuable research opportunities for future scholars.

The findings illustrate management systems as the most popular Industrial engineering domain. This is closely accompanied by operations research and manufacturing systems engineering. When analysing the domain, it is evident that the gaps in the puzzle are statistics, psychology, accounting and economics.

These are critical areas of research that Industrial engineers can invest their interests in, to address the current challenges that South Africa faces in terms of socio-economic issues including and not limited to youth unemployment rates and economic sustainability [12]. Another pertinent area of research is the role Industrial engineers may have in combating climate change.

In terms of the body of knowledge, engineering management, design and manufacturing engineering, product design and development, and operations research and analysis had the highest surge in research. Given the current research trends in Industry 4.0 adoption in South Africa, the aforementioned bodies of knowledge are critical to ensure successful implementation. Ergo, these bodies of knowledge are currently the highest in terms of publications.

Inadvertently, given the political climate and energy crisis in South Africa, it is surprising that supply chain management, facilities engineering, and energy management were the lowest bodies of knowledge, followed by safety. Subsequently, these bodies of knowledge present the opportunity for new pieces in the IE puzzle of research. This research study articulates the value of the current research in SAJIE, whilst illustrating the missing pieces of the IE research puzzle. Much like the process of completing a puzzle requiring concentration, patience and strategy, research endeavours should also adapt these techniques when exploring future research topics.

While the 1985 definition of Industrial Engineering is old, much of the traits of the modern industrial engineer are still aligned with this definition. The missing pieces of the IE research puzzle should be leveraged for future research in Industrial Engineering to encompass and expand on the 1985 definition.

ABSTRACT

This paper explores the use of a systems engineering approach to establish a canine system for application as one of the force multipliers to address complex challenges such as illicit wildlife trafficking, policing and border management. The proposed approach takes a life cycle view of the system, focussing on all life-cycle aspects from idea inception, through acquisition, operations and support to phase-out. The paper describes the systems engineering viewpoint taken and subsequent approach followed, in context of relevant international standards, to tackle the problem at hand, showing that systems engineering may be used as a valuable tool in tackling non-traditional engineering problems. The paper discusses activities undertaken during conceptualisation such as requirements definition for the capability (including pointers on how to specify the canine itself); provides guidance for executing development and acquisition; details aspects to be considered and managed during utilisation and support; and proposes a process for canine retirement.

Keywords: systems engineering approach, life cycle view, canine system

1 INTRODUCTION

Our new normal is a multi-dimensional, ever evolving puzzle, where the interrelationships between the pieces is not necessarily apparent. As puzzle builders shaping our next normal, engineers are required to architect equally complex, innovative and/or integrated solutions in response.

The establishment of a canine system is in all likelihood a less traditional problem engineers are required to architect, innovate and/or integrate a solution for. Typically it would be viewed as a simple procurement of canines that would rapidly expand into additional procurements for the missing supporting elements, still without ever recognising it as a system. This paper addresses aspects that may be considered by humans (engineers and other stakeholders) when establishing a canine system by taking a systems engineering viewpoint of the life cycle (conceptualization, realization, utilisation and disposal [1]) of such a system.

The International Organization for Standardisation (ISO) and International Electrotechnical Commission (IEC) Standard ISO/IEC 15288:2008 [2] was in effect at the time of executing the project that inspired this paper and was then used to guide the establishment of that canine system. For the purposes of drafting this paper, the relevant life cycle processes as defined in South African National Standard (SANS) 15288:2020 [1] and elaborated on in SANS 24748-2:2021 [4] were consulted and the tailoring thereof described in the paper. There is a specific focus on a sub-set of the technical processes. It is acknowledged that other life cycle processes (e.g. technical management processes such as the configuration management process [1]) are applicable and that the life cycle processes may be applied iteratively and recursively during the life cycle of the system [1], but these aspects are not addressed in this paper. The paper also strives to describe aspects that would typically be considered during the establishment of a canine system to be used in wider safety and security applications. This is consciously done in an effort to desensitize information.

2 BACKGROUND

2.1 The Canine System

This paper should be read in the context of a scenario where a project is launched to establish a canine system. The canine system includes the canines, their handlers and the support "products" required to enable the functioning of the system e.g. veterinary services, canine housing, training services, recreational facilities and logistic support services such as the supply of food, grooming products, canine transportation and recreational equipment. The canine system is used as a force multiplier in combating illicit wildlife trafficking, policing, the rendering of security services or border management. As a force multiplier, the canine system forms part of a system of systems (SoS) and may be treated as a constituent system in line with SANS 21840:2020 [3] where the technical processes may be employed for both the SoS and the constituent system or, where applicable, for the constituent system rather than for the whole system [3].

With the understanding that the presence of the canines in the operational context impacts the behaviours of the actors in the various scenarios, who adapt and evolve to counter the canine impact, the operational context could be considered complex adaptive. In the same way, in order to remain relevant and effective, the canine system has to adapt and evolve with the continuously changing environment, making it a complex adaptive system [10]. As we are dealing with this complex adaptive context, the canine system cannot simply be procured and integrated as a fully functional system. One rather has to view the canines, their handlers and other elements as analogous to raw materials that have to be shaped into a product that stakeholders desire.

2.2 Systems Engineering and the Value of Following a Systems Engineering Approach

SANS 15288:2020 defines systems engineering as an "interdisciplinary approach governing the total technical and managerial effort required to transform a set of stakeholder needs, expectations, and constraints into a solution and to support that solution throughout its life" [1]. Systems engineering is typically used when developing more traditional systems such as aircraft systems, space exploration systems and power generation systems.

Following a systems engineering approach allows the solution developers (or puzzle builders) to take a bigger picture, life cycle view of the problem and to, in the context of that, construct the solution puzzle pieces that address the problem and is supportable throughout its life. It should therefore also be applicable to the development of more non-traditional systems, as explored in this paper. The paper strives to highlight this take on the application of the technical processes [1].

2.3 Systems Engineering Standards

There are a number of international standards that guide the application of systems engineering and it may therefore be regarded as best practice to follow such standards when applying a systems engineering approach. The following standards were consulted and utilised during the development of the canine system:

- The "Systems and software engineering – System life cycle processes" standard (SANS 15288:2020) [1]. The intent of SANS 15288:2020 "is to provide a defined set of processes to facilitate communication among acquirers, suppliers and other stakeholders in the life cycle of a system" [1].
- The "Systems and software engineering – Guidelines for the utilization of ISO/IEC/IEEE 15288 in the context of systems of systems (SoS)" standard (SANS 21840:2020) [3] that "provides guidance on the application of processes in ISO/IEC/IEEE 15288 to systems of systems" [3].
- The "Systems and software engineering – Life cycle management - Part2: Guidelines for the application of ISO/IEC/IEEE 15288 (System life cycle processes)" standard (SANS 24748-2:2021) [4]. This standard provides application guidance for the SANS 15288 standard [4].

The standards above are South African versions of the corresponding international standards and are prepared by the South African Bureau of Standards in line with an international agreement [1], [3] and [4].

3 TECHNICAL PROCESSES CONSIDERED IN THE ESTABLISHMENT OF A CANINE SYSTEMS

SANS 15288:2020 clarifies that the technical processes are employed "to define the requirements for a system, to transform the requirements into an effective product, to permit consistent reproduction of the product where necessary, to use the product to provide the required services, to sustain the provision of those services and to dispose of the product when it is retired from service" [1]. During the establishment of the canine system, the tailoring and application of the technical processes specifically focuses on the processes, activities, tasks and outcomes that contribute to requirements definition, the transformation of requirements into an effective product/service (development and procurement/acquisition), the use and sustainment/support of the product/service, as well as the disposal of the product/service. These are discussed in more detail in the sub-paragraphs below. An overview is provided of the processes that either provide an input to (e.g. mission analysis and stakeholder needs and requirements definition) or are triggered as a result of the aforementioned processes.

3.1 Mission Analysis Process

The problem/opportunity space [1], [3] is typically defined at SoS level and the resulting objectives provide the context and key parameters [1] for the establishment of the canine system.

When characterizing the solution space [1], [3], the following aspects should be addressed:

- The preliminary life cycle concepts [1] are considered. Typical functions that the canine system may fulfil include "tracking, trailing and identification" [5]; "suspect apprehension" [5]; as well as "detection" [5]. The defined objectives serve as a guideline to determine the deployment concept for employing one or a combination of these functions. For combating illicit wildlife trafficking, the acquirer may wish to use canines for the tracking of poachers in a protected wildlife area and/or for the detection of wildlife products at entry/exit points, whereas detection canines may need to be employed at border posts to detect plant and animal matter, as well as narcotic substances illegally being smuggled.
  Preliminary concepts for support also need to be considered, as this impacts the procurement strategy e.g. when a turn-key solution is considered as a solution alternative, this could include training for canines and handlers, kennelling and veterinary services, whereas an in-house solution alternative may include the establishment of a breeding program and veterinary services amongst others.
  In addition, preliminary concepts for the retirement of the individual canines and the canine system need to be developed.
- The interface and interaction [3] between the canine system and current/planned systems (e.g. the existing/planned patrol functions using foot patrols, vehicle patrols and/or aircraft patrols and existing/planned access control/management functions) need to be considered and defined. The canine system is employed in conjunction with existing/planned functions e.g. tracking canines and their handlers may be used along with vehicle/aircraft patrols or may replace/supplement foot patrols. Access control/management functions may be supplemented by the canine detection function. Other constituent systems in the SoS and their functioning may therefore have an impact on the preliminary deployment, operations and/or support concepts.

The output of the solution space characterization yields a list of potential services and broad sustainment options for selection based on criteria developed during the execution of the decision management process [1].

3.2 Stakeholder Needs and Requirements Definition Process

Various stakeholders have an interest in the canine system, these include the project sponsor, donors, the acquirer, the canine unit, canine handlers, suppliers (e.g. breeders, training providers, veterinarians), the regulator, the relevant Sector Education and Training Authority (SETA) and/or interest groups (e.g. general public, World Wildlife Fund, etc.).

Stakeholder needs are identified through direct interaction with relevant stakeholders [1] and through exploring inherent and unstated needs [1]. This may require that the engineer steps out of their normal comfort zone of the "traditional" system and engages with recognized domain experts such as other service providers using canines as a force multiplier (these include the South African Police Service (SAPS), the Department of Agriculture, Land Reform and Rural Development (DALRRD) and conservation organisations such as Singita [11] who use working canines); veterinarians; working canine breeders and animal behaviouralists. These engagements are generally extremely valuable and are indispensable when it comes to gaining a thorough understanding that supports effective needs and requirements definition.

Gaining an understanding of relevant legislation and the stance of professional bodies/councils is essential to ensure that requirements are formulated in context. An example where this is applicable, is the docking of canine tails. Tail docking is not condoned by the South African Veterinary Council (SAVC) (the statutory body regulating the South African veterinary and para-veterinary professions) [6] as it may be regarded as maiming of an animal [7] in terms of the Animals Protection Act No 71 of 1962 [8]. This essentially makes tail docking illegal in South Africa as a person docking the tail of a canine, without a sound medical reason [6], [7], may be prosecuted for contravening the Animals Protection Act No 71 of 1962 [6], [7], [8]. It should be ensured that this (possibly unstated) need be translated into a stakeholder requirement, by specifying that canine tails shall not be docked.

The preliminary life cycle concepts identified should also be explored and unpacked to identify and develop the required capabilities [1]. It should be clarified what operational function or combination of functions the canine system should fulfil. Typical questions to be resolved, include:

- If tracking canines are required, will they need to work individually or as a pack?
- Will tracking canines be required to protect their handler? And suppress hostile elements?
- Will detection canines be employed in an environment where there is an interface to the general public?
- In what environment will the canines be deployed?
- Do the project sponsor and acquirer require a turn-key solution? If so, it needs to be unpacked to what extent “turn-key” is envisioned, for instance, does it include that the supplier also identifies canine handlers, secure their services and provide those handlers as a contracted-in service. Will canines be acquired or “leased”? Will canine kennelling and/or handler accommodation need to be provided by the supplier?
- What enabling systems are required for the canine system throughout its life?
- How will canines be retired?

The answers to these questions aids in the formulation of the stakeholder requirements set.

In some instances, the stakeholder needs are not aligned, as an example when considering the retirement options for individual canines, a representative from a stakeholder group may have a need that the sole retirement option for the canine is rehoming with the handler, whereas another stakeholder group may require that broader options are considered.

It is therefore important that stated and derived stakeholder needs and requirements are prioritized and formalized into a defined requirements set [1] which is approved by the project sponsor and acquirer (as a minimum).

Constraints [1] on the canine system and quality characteristics [1] of the system should also be identified and the stakeholder requirements should be formulated in the context of these. Examples of constraints that may have an impact, are:

- A working canine and handler pair form a very close bond [12]. If the canine or the handler is not available, introducing a substitute canine or handler will likely decrease the effectiveness of canine operations. This imposes a constraint during the operations phase.
- The personal circumstances of handlers and their families (handlers may live in accommodation where pets are not allowed) may preclude the option of rehoming the retired canine with its handler. This puts a constraint on the system in terms of retirement options.
- If donor funding is used to establish and initial operations and support of the canine system for a limited period, this may put constraints on system options in terms of long-term sustainability.

Performance characteristics during establishment, operations, support and retirement should be determined. Examples are illustrated in the table below.

Table 1: Performance Characteristic Examples

Establishment	Operations and Support	Retirement
Canine provider track record	Canine and handler competency test results	Eligibility criteria for canine retirement
Training provider accreditation	Measures of stakeholder satisfaction e.g. detection success rate and/or tracking success rate	Suitability criteria for rehoming canine with handler
Handler screening criteria	Response time of veterinarian to attend case	New owner selection criteria
Canine screening criteria	Timeliness of canine food delivery	Post-rehoming assessment criteria
Canine and handler competency test results		

Once the stakeholder requirement set is formalized, it should be ensured that they are aligned with and traceable [1] to the project brief.

3.3 System Requirements Definition Process

The objective of the system requirements definition process is the creation of a measurable requirements set specifying the characteristics, functionality and performance [1] of the canine system. The sub-paragraphs in this section provide an overview of some aspects that should be addressed for canine system requirements definition.

3.3.1 Canines and Canine Selection Requirements

3.3.1.1 Requirements Generally Applicable to Working Canines

There is a sub-set of requirements that will need to be specified for all working canines. Some of the more interesting requirements and the rationale behind them are highlighted in this section.

The environmental conditions under which canines will work, impacts the requirements. Should the canines be deployed in a nature conservation area to combat illicit wildlife trafficking, it is important that they can co-exist with the wild animals in the area. This necessitates that requirements related to the following be considered:

- That females be spayed to ensure that they do not need to be withdrawn from service for the duration of their heat cycle as the attraction of hyenas may pose a danger to the working canine and the handler.
- The harsh heat and humidity conditions in Sub-Saharan Africa may also impose requirement(s) that canines, which are predominantly deployed outdoors, have suitable skin (no light skin pigmentation) and coat conditions to work in such an environment.
- Another environmental aspect that should be considered, may be the requirement for canines to able to work in noisy environments where they may be exposed to operational hazards such as gun shots, vehicle noise and aircraft noise. It may even be necessary to specify that canines be socialised to travel in vehicles and aircraft or to work in the proximity of humans or wild animals.

Should the working canines be required to work in an environment where the general public are exposed to them (e.g. detection canines working in aircraft terminals), a sound temperament and proper socialisation are requirements.

Some of the more obvious requirements that may be specified for canines relate to the health of the canine and include aspects such as:

- Proportionate height, weight and build.
- Age.
- The absence of congenital abnormalities and social anomalies.
- Good general health (no broken/damaged teeth, no external parasites and valid vaccinations and deworming).

3.3.1.2 Requirements Applicable to Tracking Canines

In the context of a canine system used as a force multiplier in safety and security applications, tracking canines are required to track human scent and locate article handled by a human. It is important to identify and specify the articles that the canine should be able to find e.g. clothes and discarded items such as fabric/leather objects (e.g. bags), plastic/glass objects (e.g. bottles) and metal objects (e.g. knives).

For tracking canines, the environment and terrain in which they will work influences the requirements. The heat and humidity experienced may preclude certain breeds from being suitable. Ambient conditions such as temperature and humidity influence the location and detectability of the scent ("airborne odour plume") to be tracked [9] and it may be necessary to specify the maximum age of the scent (say 3 hours [9]) that can be tracked. When tracking canines are required to work in all terrain, it may be a requirement that the canine can swim.

The required behaviour (e.g. to lie down and stay) of the canine in dangerous situations (e.g. during gun fire) should also be specified.

3.3.1.3 Requirements Applicable to Detection Canines

The following aspects are typically specified for detection canines:

- The specific items to be detected.
- Whether the canine is required to work on- or off-leash.
- Whether passive or active indication of detected items is required.
- That canines should be able to detect items located in vehicles/luggage without the vehicle/luggage being unpacked.

3.3.1.4 Requirements Applicable to Canine Selection

Physical characteristics (as described in paragraph 3.3.1.1) and behavioural characteristics play a role in canine selection [12]. Required behavioural characteristics include "playfulness" [12], "intelligence and obedience" [12], "fearlessness" [12] and "boldness" [12].

Depending on the specific application of the canines and the environment in which the canine will be applied, it may be necessary to specify specific dog breeds. Breeds such as Labrador Retrievers, German Shepherds, Terriers, English Springer Spaniels and Border Collies [12], as well as Belgian Shepherds and Weimaraners [11] are popular detection canines. Due to environmental conditions, it may be wise to exclude German Shepherds as detection canines in a nature conservation area subjected to frequent hot, humid conditions due to their thick coats.

3.3.2 Canine Handler Requirements

Canine handlers are required, as a minimum, to be fit [12], motivated to work as a canine handler and well trained [12].

3.3.3 Enabling System Requirements

Enabling systems are deployed to provide the canine system with support as needed throughout its life [4]. It is important that consideration be given to this, as these systems should also be planned for and established to ensure that the "product", desired by the stakeholders, functions throughout the life as expected. To this extent, as an example, the training system for canines and handlers may be viewed as a production and maintenance system, with its own requirement set. Individual canines and handlers are inputs to the training system. These inputs are subjected to the production process (initial training) and shaped into the required product. This "product" needs to meet its performance requirements (e.g. be able to track a 3 hour old scent [9] or identify a specified number of different types of plant/animal/narcotic materials/substances), before it is delivered into service. While in service, the training system receives previously trained canine and handler pairings for "maintenance" (refresher training or adapted/enhanced training). Following maintenance, the "product" will again need to be subjected to "acceptance testing" to ensure that the performance requirements can still be met.

Some of the more interesting requirements that need to be considered for the enabling system, are:

- In what type of an environment will the canines be housed? If canines are exposed to extreme conditions such as a harsh climate with high ambient temperatures and high humidity or even an extremely cold environment, it may be a requirement to house canines in an environmentally controlled kennel.
- Canines will require a recreational area. If the canine unit is based in a town/city, a park may be considered as a recreation area, but in a nature conservation area, it may be necessary to create a dedicated area for canines to relax and play.
- Canines and handlers will require a training area. If the canine unit is not too geographically dispersed, it may be most effective to consider a centralized training area.
- Training aids will also need to be specified. It may even be necessary that it be specified that training service providers be in possession of the necessary licenses to keep training aids such as wildlife products, explosives or narcotic substance required for the training of detection canines.
- Logistic aspects such as the supply of food, leads, grooming products and veterinary services need to be addressed as requirements.
- Training instructors should be registered with the relevant SETA to provide training to canines and handlers.

Some of the enabling systems may be dependent on customer furnished items (CFI), such as kennels and handler accommodation, being provided by the acquirer. This poses a risk to the system establishment schedule. The timeliness and quality characteristics of CFIs should therefore also be specified.

3.4 Architecture Definition Process

Iteration(s) of architecture definitions are applied and evolved during the execution of the preceding processes [1] with the output being an agreed upon solution that is selected from the alternatives presented [1].

In the case of canine system establishment, this will be chosen options for:

- The types of working canines (tracker canines, suspect apprehension canines and/or detection canines [5]) to be employed.
- The way handlers, training, veterinary services and logistic support services will be "contracted" i.e. in-house or contracted-in.

- Re-supply i.e. will future “product batches” be “produced” in-house through the establishment of a breeding program and/or a handler training academy or will “resupply” take place through procurement of canines and/or the appointment of handlers.
- The way canines will be retired.

3.5 Design Definition and System Analysis Processes

For the establishment of a canine system, it is necessary to dip into design definition and system analysis iteratively, while undertaking system requirements definition. This ensures that the “design” characteristics of each of the system elements are unpacked in sufficient detail to produce comprehensive procurement and development specifications that are traceable to the original stakeholder requirements.

3.6 Implementation and Integration Processes

3.6.1 Preparation for Implementation

The implementation process is kicked-off with preparation activities [1]. In the case of canine system establishment this includes preparing a procurement specification for the procurements of canines, handlers and/or enabling system components/services. The procurement specification is supplemented by defined functionality evaluation criteria and associated definitions of the functionality scores (scoring points) for each criteria, allowing the acquirer to objectively assess proposals before selecting supplier(s). Typical criteria that may be considered, include the supplier’s track record and experience; facilities and perceived quality of service; compliance to stated requirements (including schedule requirements); quality of proposed training curriculum for the training of canines and canine and handler pairings.

Table 2: Facilities and Perceived Quality of Service Example Criteria

Aspect to be evaluated:	The supplier's facility and quality of service shall be evaluated by means of site visits by the acquirer.

Criteria for evaluation:	During the inspection, verify that the supplier has: • A sufficient supply of canines available for selection (say 30% more than the required number). • Onsite canine kennels, food, veterinary services, training facilities, training material and -aids. • Access to facilities to accommodate canines and handlers during training. • An active hygiene and pest control program is in place at the kennels. This is evidenced by processes, procedures and/or records. • Facilities to safeguard training aids such as firearms, ammunition and/or contraband items.

Proposed assessment of functionality score:

Scoring points	5	During the site visit the facilities and perceived quality of service is excellent with all requirements fulfilled.
	3	During the site visit the facilities and perceived quality of service is satisfactory with 1 deviation from the requirement.
	1	During the site visit the facilities and perceived quality of service is mediocre with 2 deviations from the requirement.
	0	Don't comply i.e. during the site visit the facilities and perceived quality of service is unacceptable/poor with 3 or more deviations from the requirement.

3.6.2 Undertaking Implementation and Integration

During implementation, the focus is on the realisation of all the system elements within the constraints [1]. For the canine system establishment, the coordination and timing of implementing the various elements is key. This includes actively managing the delivery of CFI to ensure that it is well coordinated with other project activities. Implementation therefore requires dedicated project management and liaison between all parties to ensure that kennels are ready, food is available, veterinary services are in place and training is concluded before the canines are delivered.

During integration the various system elements are integrated, the interfaces activated and it is verified that the integrated elements work together as required [1]. Typical aspects that require attention during the establishment of the canine system include that the external interface with existing systems function as required e.g., that trained canines are indeed able to travel in vehicles/aircraft and react appropriately to noisy environments or that detection canines are docile enough not to threaten travellers at border posts while executing their detection duties. For internal interfaces, it can typically involve verifying that the training was effective and that the kennels/recreational areas fulfil the intended purpose. Evaluation of the effectiveness and efficiency of the canine and handling pairing is also an important integrated component that needs to be evaluated and managed. It is clear that integration can never be a once-off for a complex adaptive system like a canine system and that through-life effort is required to manage certain aspects of integration.

3.7 Verification Process

Even though the scope of verification spans wider, this paragraph specifically focusses on the verification of canines and handlers.

Verification criteria are predefined as well as the remedial actions should the "item" not comply with the specified requirements.

3.7.1 Preliminary Verification

During establishment it is confirmed that the canine is "built right" [1]. This is initially done though preliminary acceptance where the canine and its documentation are examined to determine:

- Its general condition and health (assessment for build, condition of teeth and absence of parasites).
- Compliance to the absence of physical abnormalities such as the specified grade of hip dysplasia. This is typically done by means of x-ray examination.
- Its age, breed and vaccination status.

Another aspect to be verified during the preliminary acceptance, is the potential of the canine to successfully work in the role assigned to it. Here the canine's personality is evaluated to check it's response to strangers (important for canines with public facing assignments), as well as it's "playfulness" [12], "intelligence and obedience" [12], "fearlessness" [12] and "boldness" [12].

By the same token, potential handlers are assessed for their suitability to become a professional canine handler. Some of the criteria that may be used to assess the suitability of handlers include "level of fitness" [12] and the handler's "knowledge of dog training and handling principles" [12].

Should a canine or a handler not meet the criteria, the "item" is rejected and an alternative subjected to verification.

3.7.2 Interim Verification

By this time the canine and handler have been integrated as a pair and initial training is concluded. An assessment is used to verify that the pair functions as required in a training environment.

Should it be found at this point that the canine, handler or canine and handler pair is not suitable for performing the intended assignment(s), retraining should be considered or it will be necessary to make some replacements.

3.7.3 Final Verification

Once ready for deployment, the canine and handler pair are independently assessed in the operational environment, prior to the release for service. This final step of verification also verifies the implementation of the interfaces (see paragraph 3.6.2).

A similar acceptance strategy may be followed to that implemented for interim verification.

3.8 Transition Process

During the execution of this process the canine system, comprising of the canines, handlers, enabling systems (kennels, recreational facilities, logistic support, training system and veterinary services), is introduced into service and functions together with the other SoS elements employed as force multipliers. During this period the operation of the system and its interfaces are closely monitored as (the initial) part of the validation process.

3.9 Validation Process

Here it is confirmed that the “right product is built” [1] i.e., that the canine system is the right product to fulfil the intended purpose [1]. Typical measures that may be used to quantify this for the canine system include a specified improvement in the suspect apprehension rate and a reduction in poaching statistics [11].

3.10 Operation and Support Processes

The management of operations and support of the canine system should be done in the complex adaptive context, where changes (such as changes in the intended purpose, the environment or the scope of services required from the system) are proactively monitored and their impact used to guide the rejuvenation of the canine system. As an example, when initially introduced, detection canines may be trained to detect elephant ivory [11], [13], but as conservation threats evolve it may become necessary to add other animal products (e.g. pangolin scales [13] and rhino horn [11], [13]) to this.

As a minimum the canine and handler pairs should be continuously assessed for competency and refresher training undertaken regularly.

3.11 Disposal Process

Disposal of the canine spans far wider, but for the purpose of this paper, only canine retirement and rehoming is addressed here. If a canine needs to be retired due to medical reasons, euthanasia could be considered as a viable option. If this is not the case, the canine can either be rehomed with its handler or a suitable new owner. This process [14] is illustrated in Figure 1.

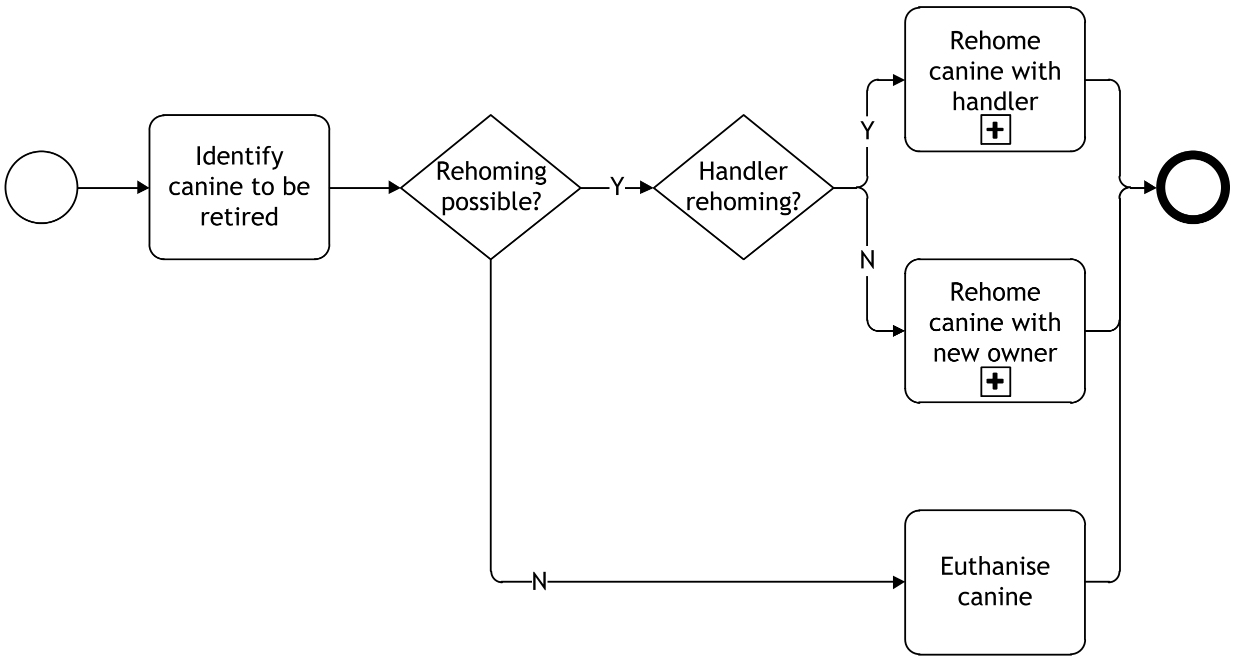

Figure 1: Potential Canine Retirement and Rehoming Process [14]

Depending on the circumstances, the “sub-processes” [15] (shown with a [+]) are to be unpacked to cater to the unique situation posed.

4 CONCLUSION

With the evolving problem spaces faced by engineers, the non-traditional application of tools and techniques at our disposal may be required to architect complex, innovative and integrated solutions for our next normal.

This paper illustrates that system engineering processes and principles may be used to address non-traditional problems such as the establishment and operation of a canine system for utilisation as a force multiplier in combating illicit wildlife trafficking, policing, rendering of security services or border management, as well as other socio-technical problems posed in the International Council on Systems Engineering (INCOSE) South Africa's annual "Greatest Young Systems Engineers of the Year Challenge" [16]. It is therefore recommended, and readers are encouraged to consider applying a systems engineering life cycle view when engineering appropriate solutions for our next normal.

ABSTRACT

South African (SA) rail network has struggled with challenges of theft and vandalism of the infrastructure, and the accidents caused by human interface to the system. It is for these reasons that there is a need to seek engineering solutions, such as cyber-physical rail, enabled by the fourth industrial revolution (4IR) technologies. For the SA rail organisations to better prepare for introducing these technologies, the emphasis should be made on the planning process. One of a better-suited planning tool for this type of complex technologies is technology roadmapping. A qualitative study was used to find the ideal framework for the development of the customised technology roadmap for the SA rail sector and investigate the critical factors of the 4IR which must be considered during planning process in the context of rail. Using a mixture of deductive and inductive qualitative analysis approaches, this study identified a set of factors for the customisation of the technology roadmap for the SA rail sector.

Keywords: fourth industrial revolution, technology roadmap, rail sector, planning

1 INTRODUCTION

Changes in markets and technologies necessitate the need for organisations to be dynamic and adaptable. Organisations use technology strategic plans to deal with these changes, as well as come up with new technologies that will meet the requirements of customers and gain competitive advantages. Technology management is an important activity within an organisation, to meet customers' needs; this requires techniques or tools to support the planning process of technology management [1]. It may be defined as, "the process of managing activities within the framework of technology management to improve the technology capability of the organisation". A technology management framework incorporates the following activities: identification, selection, learning, acquisition, exploitation, and protection" [2].

One of tools that can be used to manage technology in dynamic and complex environments is technology roadmapping. Technology roadmap is a long-term plan for the strategic management of technology; it is a guide an organisation must follow to achieve its technology strategies. Before a technology roadmap may be developed, an assessment of the organisation or sector must be conducted to evaluate what type of technology roadmap would be valuable.

Therefore, the objectives of this research were (i) to investigate the customisation of the technology roadmapping for the South African rail sector and (ii) to investigate the critical factors that can be incorporated in the development of technology roadmap for planning of the fourth industrial revolution (4IR) technologies.

Like any sector, the South African rail sector has major challenges, and the use of the 4IR technologies could possibly reduce most of these challenges. Some of the challenges within the South African rail industry include driver inattention and distractions, train collisions due to manual authorisation, overloading of trains, run-through and derailments, theft and vandalism, and level crossing incidents. The following are technological challenges: unreliability of the network due to old equipment and constant failure, unavailability of the network due to lack of maintenance, power failures or unstable power supply, rolling stock failures and lack of technological surveillance.

There is an agreement that the transport industry is one of the top three industries for Internet of Things (IoT) investment, based on the spending estimates [3-4]. While both PRASA and Transnet have projects running in the rolling stock department to adopt some of the 4IR technologies, this is not enough, as the challenges in maintenance and customer experience are still affecting the organisation. The South African rail sector will benefit from the 4IR as a solution to the technological challenges and other challenges that may be solved by automation of the operations. Transnet is one of the largest rail operators in Africa, as it links to other countries; it is both a passenger and logistic rail operator. Transnet owns blue trains, which are the passenger trains and Transnet freight, for transporting goods. PRASA is a passenger rail owner and operator; it owns both Shosholoza Meyl, the long-distance passenger rail service within South Africa and Metrorail, the urban passenger rail service within South Africa.

2 LITERATURE REVIEW

2.1 The rail technologies network and the fourth industrial revolution

The network of the Radio Train Control Systems is made of the advanced train administration and communications system (ATACS) and communication-based train control system (CBTC). These systems allow the train to auto-detect its own position on the network, and also allow control through the dual radio transmission between the onboard and the trackside system. They reduce the number of the trackside or wayside equipment and also allow for corporation between onboard and trackside equipment using advance radio technology to allow high density operation, power saving and automatic operation. These are some of the systems that can be installed in the South African network to assist reduce theft of trackside as there will be less equipment outside.

Van Der Meulen [5] states that rail dominates in the following market spaces:

- Heavy haul (bulk commodities)
- High speed intercity (passengers)
- Heavy intermodal (double stack containers)

Tokody & Flammini [6] believe that rail has suffered from a lack of long-term strategic planning. Not only are there continuous changes in technological developments, but they also believe that the rail can benefit from the development of the smart technology (associated with the 4IR), which require long term-strategic planning. The 4IR technology can handle high volume data (big data) and it also provides real time data to make decisions quickly, which allows for decentralisation.

Figure 1 is a basic diagram of the integration of the rail systems for the smart rail. It shows different technologies that make up the smart rail system. This diagram shows systems that are generic to both commuter rail system and freight rail and it can be used for planning of Rail 4.0.

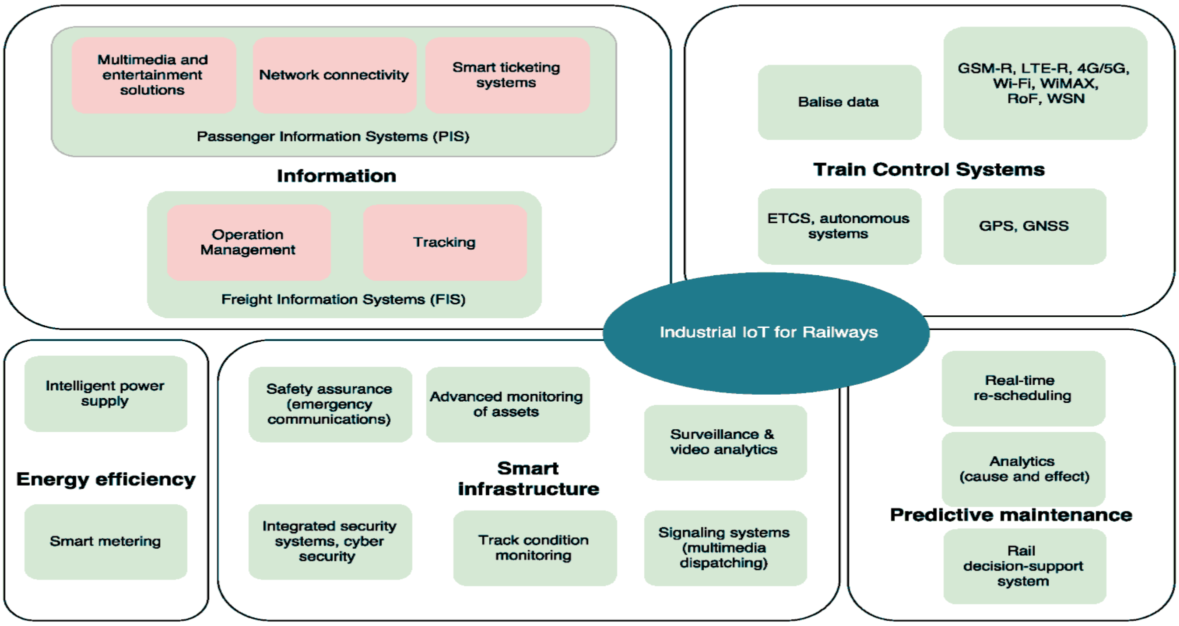

Figure 1: Industrial IoT Enabled Services Relevant for the Rail Operation [7]

Tokody & Flammini [6] and Pieriegud [8] believe that the development of intelligent and autonomous systems will have a positive effect in the rail, especially regarding the improved safety, infrastructure, and sustainability. The 4IR technologies will provide the following benefits [8]:

- Mobile Application
- E-ticketing.
- Digital train control.
- Signalling and traffic management.
- Digital platforms for predictive maintenance.

Some of the key characteristics of the 4IR are big data, cyber cloud, and artificial intelligence. These technologies are about being able to share information that is saved in the web;

however, the biggest problem with the web is security of information as well as the implementation of a new emerging technology.

Lee, Singh and Azamfar [9] propose a solution and refer to a step-by-step roadmap for the implementation of integrating physical systems (products) with cyber systems; it also touches on the block chain as technology that can significantly improve the cyber system. Block chain is also new technology and requires further research before it can be implemented. For the above solutions to be successful, proper planning is required. This is true with the implementation of emerging technologies of the 4IR. As organisations are planning for the implementation or development of 4IR technologies, cyber security is a factor that must be considered and planned for.

One of the biggest challenges of the 4IR is the investment required for new technologies. Some companies do not have funds to readily invest in more advanced technologies. There are also other costs, such as the cost of training. It will be required that employees must be trained, and these costs can hinder the plans towards the implementation of the 4IR. When speaking about the 4IR, most organisations only concentrate on the development of technology, and not the development of the whole value chain of the organisation, like the knowledge management of the organisation, business processes, etc.

People, or the 'human factor' of the organisation must be advanced into more creative roles and concentrate on activities that add value, while machines will do the repetitive and routine activities [10]. Organisations that fail to realise this will be met with challenges, especially from labour unions.

The planning of the 4IR must find a way to deal with challenges and barriers that may delay the implementation of its technologies; for example, how to develop or upskill the current workforce to adapt to the new technologies and new roles instead of letting employees go, as noted by Pessl, Sorko and Mayer [11]. Changes in workforce due to the introduction of the 4IR must be investigated and planned for, as suggested by Kazancoglu & Ozkan-Ozen [12]. This will assist the organisations in reducing the delays which may be due to Union Labours not approving the move towards the implementations of the new technologies.

Maynard [13] suggests teaching all stakeholders, from consumers to CEOs, about the benefits of the 4IR. This will help in reaching a consensus when planning for the development of new technologies. In the context of the South African rail sector, these stakeholders must also include the labour unions, as they also may cause delays in the development of the new technologies.

2.2 Technology Roadmap

Technology roadmap was developed as a tool for the planning of innovation [14] and it has been useful for the organisations that adopt the market-pull innovation mechanism (like the rail sector) as their aim is to improve the existing product lines in order to meet the needs of customers. It is for this reason that Hwang [15] suggested that manufacturing organisations should use technology roadmaps to plan for the 4IR, though she does not specify how it should be approached.

Roadmapping is a tool that also creates the knowledge to reach a specific vision of an organisation. It can be used as a backward planning process, through beginning with where the organisation wants to move to (the vision) and develop strategies to move towards the vision by determining the current status of the organisation and closing the gap [16]. Several scholars [17, 18, 19] agree that roadmapping is used to plan where organisations want to go, as it evaluates where the organisation is currently and analyses ways of closing the gap between the present and the future.

Muller & Phaal [19] state the following characteristics of the roadmap:

- Flexible
- Scalable and
- Can be customised to suite different strategy

While Centidamar, Phaal and Probert [17] list the following challenges or hurdles of roadmapping:

- Initiating the process (taking the first step): coordinating the team at the begin may prove to be difficult
- On-going maintenance (owning the process) of the roadmap: managing the process of roadmap may be a challenge
- Rolling out the roadmapping process within an organisation: taking the strategic plans to the departmental teams can also be a challenge

Phaal, Farrukh & Probert [1] found that keeping the roadmap alive is the biggest challenge of the technology roadmap. The breakdown of the findings based on the survey conducted and the biggest challenge is keeping the roadmap alive and on-going, which is almost 50% of the respondents' view. It is followed by the challenge of starting the process of technology roadmap at just over 30% of the respondent's view. The article does not include factors that affected the responses like the experience, qualification as well as the level of authority of the people who were in the positions of keeping the process alive and those who were involved in start-up as this information may assist with better planning going forward.

The strategic roadmap is regarded as the central artefact that serves three main purposes as noted by Erol, Schumacher & Sihn [10] in the context of the industry 4.0:

- As means to consistently analyse and plan the transformation of business models and assess the impact of technology
- As means to facilitate collaborative development of vision, strategy, and projects
- As a tool to manage and track all activities regarding the transformation process towards industry 4.0

The process flow of an example of technology roadmap based on the Figure 2 is as follows:

1. Vision- vision of the technology roadmap must be determined and agreed upon as the first step
2. Now- the current organisation's technology capabilities
3. Market
   3.1 The market requirements must be determined and known
   3.2 Plans to meet the market need must be made and plotted on the roadmap based on the planned progress of meeting them
4. Products
   4.1 Determination of products that can meet the customer needs must be demined
   4.2 Plans to acquire these products must then be made
5. Technology
   5.1 Technology required to develop and own the new product should be determined
   5.2 Then plans should be made on how and when to acquire the technology

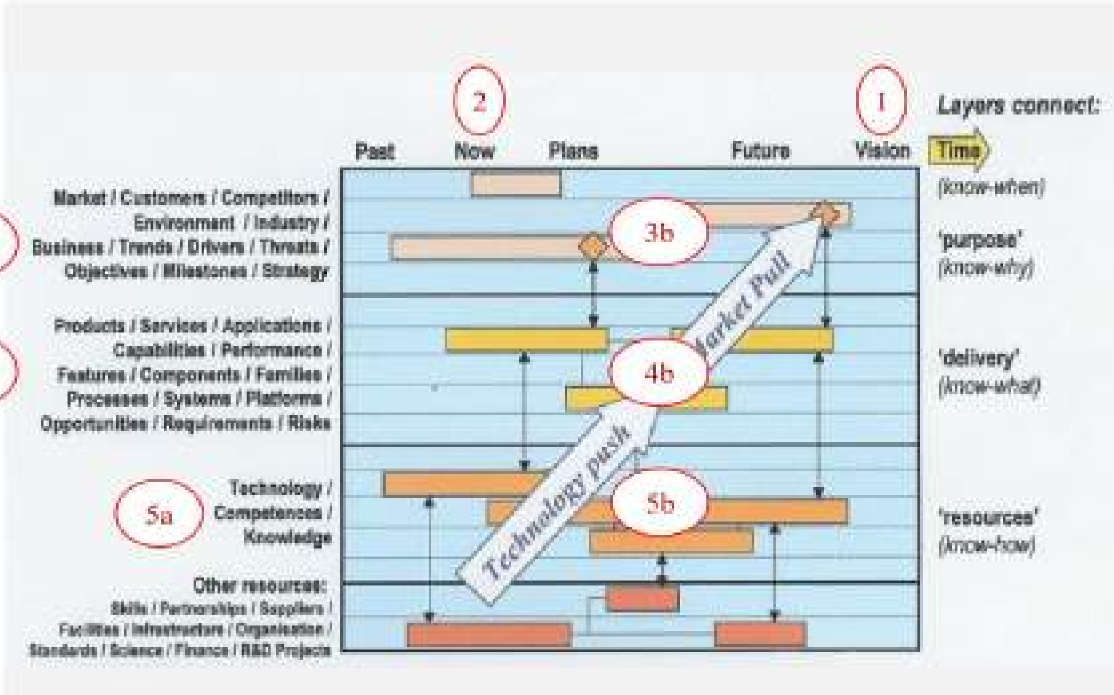

Figure 2: Example Process Step of Technology Roadmap [1]

Several scholars ([20], [18], [19]) agree that the technology roadmap must be customised to suit the culture of the organisation, or the new technology to be developed, as it will be effective. Kerr, Phaal and Thams [18] explain that the mere development of a technology roadmap is a customisation of the technology roadmap and that there is no guideline of how to customise it. Kerr, Phaal and Thams [18] further propose the use of the S-plan and customising it to the organisation. 'S- Plan' refers to the generic technology roadmap process, which can be customised to specific products or organisations, using the reference of the original generic process.

Amer and Daim [21] state that industrial or sectorial technology roadmaps require collaboration between organisations within the industry to form part of the planning process. Collaboration must thus be considered when developing the technology roadmap. When organisations collaborate on the development of the technology roadmap, stakeholders and statutory bodies must be included.

Hall [22] presented a list of stakeholders involved when developing the Roadmap for South African coal. The presenter does not say how the stakeholders were involved in the process and what benefit they brought by being involved. The participants and steering committee comprised of all 17 stakeholders. These were a collaboration of clients, private organisations, and governmental representatives.

Cetindamar et al. [20] have also come up with a strategy to customise a technology roadmap for product-service integration. This framework works differently for different technologies, depending on whether they are market pull products or technology push type of innovation.

Below (Figure 3) is the roadmap framework with the inclusion of partners as in the joint venture arrangement. This roadmap includes contribution from the different stakeholders, and this can benefit the rail industry to adopt for in the technology planning process.

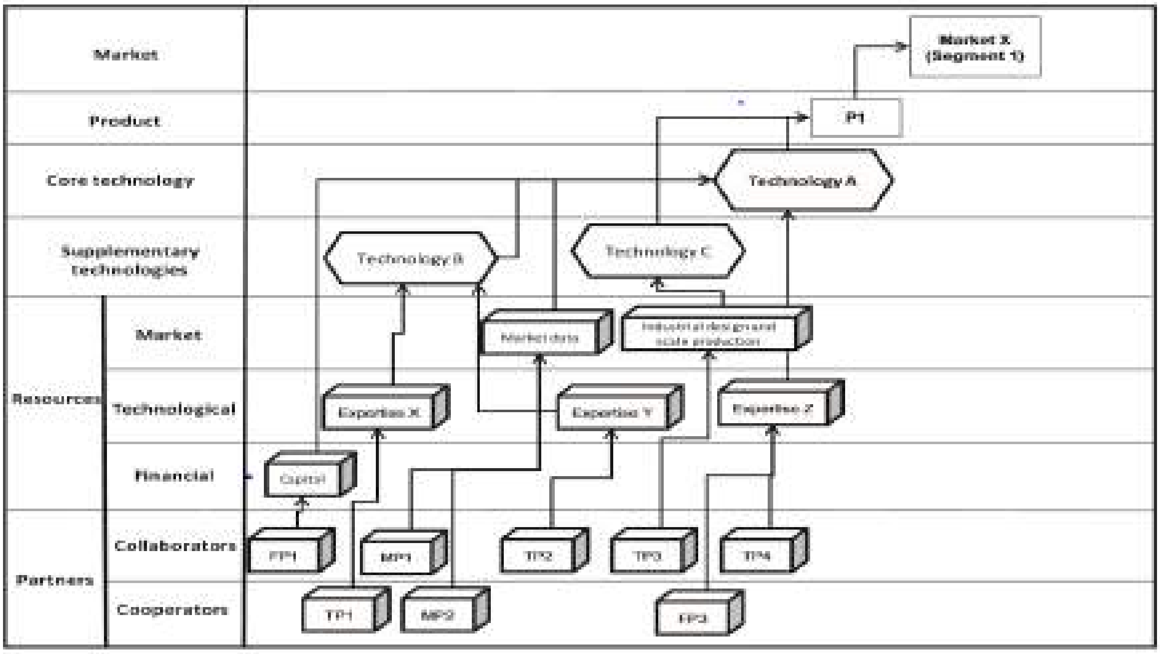

Figure 3: Multiple stakeholders technology roadmap [14]

Da Silva *et al*. [23] state that the rail sector can benefit from the use of a technology roadmap as a tool for strategic planning. Technology roadmaps are not only limited to use as a strategic process, but also for the following technology management activities, which may be on a departmental, company or sector level:

1. Identification: for technological development
2. Knowledge management: it can be used to map out the plan to follow for managing knowledge (learning activities)
3. Exploitation: the activity for commercialisation

Da Silva *et al*. [23] further identified four critical main points in developing the technology roadmap vision for the rail industry:

- Market.
- Public policies and investment.
- R&D and technology.
- People.

3 METHODOLOGY

The research methodology employed is a qualitative approach using semi-structured interviews designed to test and improve the theoretical model on technology roadmapping for the fourth industrial revolution. This theoretical model was derived through the literature review and the final model (enhanced through empirical data) is shown in the next section that discusses the results.

The questions for the qualitative interviews were divided into three categories: Category A (comprised of questions seeking the demographic information of the participants), Category B (was about the technology roadmap) and Category C (was about the fourth industrial revolution). Category A questions (used to attain the demographic data of the participants, which included data regarding the experience of the participant, experience in rail, number of years in rail, as well as the current roles and the number of years in that role). Categories B and C questions contributed to customising the planning process of the fourth industrial revolution in the South African rail sector.

This study adapted the snowball sampling technique. The years of experience of the 14 participants interviewed can be categorised as follows: more than nine participants have more than eight years' experience in their current positions, lowest experience in current experience is one year, longest experience in current position is 10 years, over nine participants have more than 14 years' experience in rail, the longest service in rail is 23 years and the least amount of experience in rail is nine years.

The respondents were drawn from the main two rail operators in South Africa and they are based in the following divisions: electrical (four), signals (three), perway (two), telecoms (one), human resources (one), ICT (one) and rolling stock (two).

The data analysis method used is a mixture of deductive and inductive quantitative analysis approaches. Therefore, the initial themes were directed by the theoretical model deduced and a more open-ended coding (grounded theory methodology) resulted with a modified technology roadmapping framework.

4 DISCUSION OF THE RESULTS

4.1 Emerging themes from the qualitative interviews

The following is a list of final themes that emerged from the interviews:

- Key stakeholders to be involved during roadmapping;
- Planning and/or technology roadmap managing team;
- Information to be discussed in planning;
- 4IR technologies in rail sector; and
- Unique features for South Africa's rail industry.

The interview responses led to a list of stakeholders that should be involved in technology roadmapping exercise and are unique to the South African rail industry. While most participants agreed on many stakeholders, there were a few who thought labour unions should be involved on planning for the technology roadmap. The idea of bringing labour representatives on board is supported by the literature of planning for the fourth industrial revolution [24]. As deduced from the interview responses, the following is a consolidated list of stakeholders who need to be involved in the planning stages of the rail industry roadmap: engineering bodies, government/ transport departments/ municipalities, consultants, rail network operators (e.g. Gautrain or TRANSNET), rail safety regulator (RSR), communities/commuters, labour unions, investors, board of directors and the security companies.

Table 1 shows the information to be gathered from stakeholders during the development of a technology roadmap and the ways to gather such information, as suggested by majority of the respondents interviewed.

Table 1: Methods and information to be gathering during technology roadmap development

Ways to gather information from the stakeholders	Information to gather during planning
• Group discussions • view sessions • Workshops • Research approach like surveys	• Opportunities of industry • Challenges of industry • Standards • Customer facing technology • Skills requirements • Funding • Specific political/ labour / stakeholders • Local manufacturing capabilities • Tools and process of sharing information

	• Integrated asset management

Some handful of the respondents believed that using artificial intelligence and automation may reduce the challenges/incidents faced by the rail organisations because they can reduce human interface. Over and above the automation and artificial intelligence, the rail industry can benefit from the technologies such as In Cab system, Electronic signaling system, Cloud based technology, big data management systems, Artificial intelligence, Digital twin/ digitalisation, Automation and Virtual reality of network.

When it comes to managing the technology roadmap for the fourth industrial revolution, some of respondents advised that there should be an information technology specialist as a member of the roadmapping committee; also, software tools should be used to make it easier for the committee and stakeholders to get information on the roadmap and progress.

The human resource (HR) manager also suggested that bringing new technology would mean there should be an upskilling of the employees and, if they (HR) can have information on products and type of technology being planned for, they can plan for the correct upskilling training.

The consolidated list of representatives who must be involved in the management of the technology roadmap development, as well as responses from participants on how to keep the team involved throughout the technology lifecycle is presented in Table 2.

Table 2: Managing Technology Roadmap

Members to be involved in technology roadmapping	**Ways to keep the technology roadmapping committee involved**
• ICT • HR • Train Operations • SCM • Legal • Finance • INFRA • Rolling Stock • Marketing • Safety • Security	• Continues review meeting • Communicate benefits of technology roadmap • Involve stakeholders through forums • Use software as a tool to manage technology roadmap

The unique features of the South African rail as listed by the respondents are the following items:

- Rail environment/ national rail policy and operator mandates
- Incorporate opportunities and challenges in the industry
- South African standards
- South African public policies
- Customer facing technologies
- Stakeholders
- Lack of technical capability of local manufactures
- Skills matrix
- Socioeconomic environment

4.2 The proposed customised framework for the rail sector technology roadmap

The following are some observations based on interaction with the participants in the rail industry on how to improve the development and usability of the roadmaps:

- There is a view that only the senior staff in organisations are often included in the development of technology roadmap; middle to senior management are included only in the implementation and the managing of technology roadmapping. As a result, some of the respondents only had an experience in the long-term strategic planning, rather than experience in the actual development of the technology roadmap. This led to missing information, as some questions were not answered, such as the question of the challenges and benefits of using the technology roadmaps.

- Most respondents were set on having private companies be involved in the planning, for the benefits of knowledge-sharing as well as on the funding of the roadmapping expected outputs.
- The skills or lack thereof, regarding the 4IR technologies, made knowledge management an important aspect, hence the recognition of involving HR at the very beginning of the planning of the technology roadmap.

The respondents introduced the activity of reviewing the roadmap but did not specify when there should be a review phase and whether it should be one review or more as well as the routine period of the reviews. This may be the point of discussion in future research.

Figure 4 shows the proposed customised technology roadmap for the planning of the fourth industrial revolution technologies in the rail sector (based on a theoretical model and the information derived from the interviews).

Roadmap Architecture		**Past**	**5yrs**	**10yrs**	**15yrs**	**20yrs**	**Information types**
Strategic goals			R1		R2		SWOT
Resources/ strategic objectives	Market						Resource plans
	Security						
	Safety						
	HR						
	Finance						
Support	Public partnership • Gov • Commuters • RSR						Partnership agreements
	Private partnership • Private rail operators • Manufactures						
Technology/ Product	Telecommunications	• In Cab system • Electronic signaling system • Cloud based technology • Big data management systems • Artificial Intelligence • Digital twin/ digitalisation • Automation • Virtual reality of network					Smart rail infrastructure system
	ICT						
	Rolling stock						
	Electrical (HC)						
	Signals						
	Perway						

Figure 4: Final Proposed Roadmapping Framework for the Rail Industry

Legend: R1- review phase 1; R2- review phase 2

This framework provides options in terms of which strategic objectives/ capability development should be pursued, a type of supporting structure that is required as well as the technology/ product options. Timelines suggested for the rail industry roadmap can range from 5 to 20 years, with the regular reviews (see R1 and R2) conducted as the roadmap is being implemented.

5 CONCLUSION

In response to the identified challenges within the South African rail industry, this paper has proposed a technology roadmapping framework for this industry. Proper long-term planning is necessary for this industry as the rail assets have a long lifecycle and the planning of acquiring these assets is also long. The technology changes faster than the assets can be changed, hence the suggestion to review the technological assets more frequently. The respondents suggested different technologies which might benefit the industry. The list is included in the final proposed framework. They also listed the type of private and public stakeholders who needs to be involved to make the technology roadmap effective.

The future research may also include private organisations, as the respondents have already listed them as the required stakeholders. Overall, this research has given more insight into the customisation of technology roadmap for the rail industry in South Africa.

ABSTRACT

Retailers frequently underutilise promotions due to the complexity involved in promotion planning and demand forecasting. In response, researchers have proposed various mathematical models to assist retailers with these decision-making processes. This article identifies these existing mathematical models by conducting a systematic literature review (SLR). Sufficient background is provided on the variables that influence the profitability of retail promotions and the modelling techniques commonly deployed within the literature. This review aims to summarise and evaluate each study in terms of the modelling approaches followed and what combination of the variables, as mentioned above, are included within each model. The findings obtained from this review may serve as a basis for future researchers in developing a mathematical model that maximises promotional profit within a retail setting.

Keywords: Retail promotion planning, Optimisation modelling, Systematic literature review, Demand forecasting

1 INTRODUCTION

Conducting retail promotions (the short-term reductions of a product's regular retail price [1]) offers many advantages to retailers. Amongst the known benefits, promotions boost short-term sales and increase store traffic [2, 3]. Additionally, an item sold at a discount induces the sale of complimentary items [4]. Finally, promotions allow retailers an additional revenue stream as vendors may offer retailers funding as an incentive for selling the vendor's items at a lower profit margin [1].

Concurrently, several adverse facets accompany promotions. To name a few:

- Customers react unfavourably to promotions if they believe their durations are restrictively short [5].
- The sale of a discounted item may prevent a substitute from being sold at a higher profit margin [6].
- Customers who stockpile items purchased during promotions are less likely to make repeat purchases. [7]. Therefore, repeat purchases that would have been sold at non-promotional margins compound losses. Designing profitable promotions over the long term is therefore complex.

Given that most retailers rely on informal heuristics to plan promotions [8], historical instances showcase the severe financial repercussions of poor promotion planning. Ailawadi et al. [7] found that 50% of promotions conducted at a large drug retailer in the USA over one year are not profitable because vendor funding does not sufficiently offset the lower profit margins on products. The authors estimate the retailer lost $52 million due to poor promotion planning. Jedidi et al. [9] come to a similar conclusion; the lower profit margins on three out of four promotional items sold at a specific retailer increase their sales but reduce overall profit by 5%. While the previous two studies showcase the profit impact of reduced margins, Kopalle et al. [10] describe a case study wherein overpromotion reduced retail profit by 7% to 31% over 124 weeks due to the stockpiling effect.

These instances of suboptimal promotion planning underscore the critical need for a more sophisticated and systematic approach to designing promotions. This is where mathematical modelling becomes pertinent. Mathematical models select the best variables with respect to some criterion amongst a set of alternatives [11]. Given mathematical models' effectiveness in finding optimal solutions to complex problems with large numbers of inter-related variables, this technique has been shown to be especially effective in outputting the optimal conditions at which to conduct promotions [12]. In response, researchers have proposed multiple mathematical models to aid retailers in designing profitable promotions. This paper identifies these models through a systematic literature review (SLR).

SLRs originated within the healthcare industry [13]. During the early 1990s, health practitioners adopted an evidence-based approach that emphasised incorporating the best available research into clinical practice [13]. A systematic review is a systematic approach to defining research questions and synthesising findings [14]. To this end, systematic reviews became popular for summarising evidence within a specific domain. Since then, many fields outside healthcare have adopted evidenced-based research practices and systematic reviews [15].

Considering the efficacy of Systematic Literature Reviews (SLRs) in synthesising evidence and the imperative of identifying how mathematical models assist retailers with designing promotions, conducting an SLR on this subject is warranted. This review's aim is threefold. Firstly, it aims to identify the mathematical models that assist retailers with promotion planning. Secondly, it evaluates them in terms of their modelling approaches. Thirdly, it evaluates them in terms of their scopes. In doing so, this paper contributes to the research by forming a basis for developing future mathematical models that ensure the effective application of retail promotions.

2 METHODOLOGY

An SLR is conducted according to the approach first described by Kitchenham [16]. Kitchenham's [16] review method is frequently followed in the literature. An inexhaustive list of reviews that follow this method includes the topics of stochastic programming models in the retail industry [17], how collaborative robots used on assembly lines impact manufacturing systems [18], and the use of deep learning approaches in detecting attributes within source code indicating underlying issues [19].

The approach divides the review into three stages. In the first stage, the need for a review is identified, and the review protocol is developed. The need for a review on the mathematical models that assist retailers with promotion planning is justified in this paper's introduction. The review protocol is defined as follows.

Five research questions are formulated to address the aim of this study. The research questions are listed in Section A of Table 1. Research Question (1) identifies the number of studies that can assist retailers with promotion planning. Research Questions (2) and –(3) evaluates the mathematical models in terms of their modelling approaches by summarising the optimisation- and demand modelling techniques deployed. Finally, Research Questions (4) and –(5) summarise the scopes of the models in terms of the retail variables that are included as well as identifying limitations within the models.

The databases Science Direct, Scopus, IEEE, and Web of Science are searched for studies that contain the words' retail', 'promotions', and 'optimisation' within the keywords, title, or abstract (hereafter referred to as metadata). Provision is made to include studies that use the US spelling of the word 'optimisation'. Section B of Table 1 denotes the keywords used to query the respective databases.

In the second stage of the methodology proposed by Kitchenham [16], studies of appropriate quality are identified, and data is extracted and synthesised. To this end, the inclusion and exclusion criteria are applied in a stepwise manner. In Step 1, the databases are searched for studies that contain the search terms within the metadata. In this step, non-English literature and literature published more than ten years ago are excluded. This ensures that the SLR only includes contemporary studies. This step identified 95 studies. Different databases may list the same studies. Duplicate studies are removed in Step 2. After this step, 66 studies remain. Given that promotions are temporary price discounts [1], a mathematical model must determine the optimal promotional price to be included in the review. In Step 3, the studies that do not use mathematical modelling to find the optimal promotional price are excluded. This step ensures the relevance of the retained studies. Ten studies remain after this step. The inclusion and exclusion criteria, as well as the number of studies each step identifies, are summarised in Section C of Table 1.

The review is reported in the final stage by evaluating them in terms of the review questions. The final stage of the methodology is covered in the subsequent section.

3 RESULTS

Table 2 lists the title, year of publication, and author of each identified study. Additionally, Table 2 summarises each of the identified studies according to its background, aim(s), and modelling approach followed.

Table 1: A summary of the review protocol

A. Research questions				
Question number		**Question**		
1		How many studies contain mathematical models that determine the promotional price that maximises retail profit?		
2		What optimisation approaches do these studies follow?		
3		How do the studies model retail demand?		
4		What combination of standard retail variables do the models include?		
5		What research gaps exist within the literature?		
B. Keywords and databases searched				
Keywords		'promotions' AND ('optimisation' OR 'optimisation') AND 'retail'		
Databases		• Science Direct • Scopus • IEEE Explore • Web of Science		
C. Inclusion- and Exclusion Criteria				
		Step 1	**Step 2**	**Step 3**
Inclusion criteria		• Studies that contain the keywords within the metadata • Studies that were published between 2013 and 2022 • English studies	• Studies that contain the keywords within the metadata • Studies that were published between 2013 and 2022 • English studies	• Studies that contain the keywords within the metadata • Studies that were published between 2013 and 2022 • English studies • Studies that use mathematical modelling to find the optimal promotional price
Exclusion criteria		• Non-English studies • Studies published before 2013 and after 2022.	• Duplicate studies	• Studies that do not use mathematical modelling to find the optimal promotional price
Number of studies from each database identied during this step	**Science direct**	15	15	3

Table 2: Summaries of identified studies:

No.	Study title	Year	Summary	Authors()
1	Optimising decisions of fresh-product members in daily and bourse markets considering the quantity and quality deterioration: a waste-reduction approach.	2021	Product waste is common within the fresh agricultural product supply chain (FAPSC). This study proposes a coordinated strategy between role players within the FAPSC that optimises retail promotions by minimising waste. Retail price is expressed as a function of price elasticity, tax rates, the number of wasted products, the selling price of wasted products within secondary markets, the stocking factor, and the wholesale-, shortage inventory-, and surplus inventory costs. The problem is modelled as **a Stackelberg game** wherein the vendor is the leader, and the retailer is the follower. The optimal retail price is obtained using backward induction.	Dolat-Abadi [20]
2	Promotion Optimisation for Multiple Items in Supermarkets	2021	This study is the successor of *The Impact of Linear Optimization on Promotion Planning* by Cohen et al. [24]. This study's predecessor focuses on the promotion of a single fast-moving consumer goods (FMCG). This study aims to optimise retail promotions by developing **a nonlinear integer programming model** that specifies the prices of multiple FMCGs that will maximise profit given specific business rules. The study inherently includes cross-item effects. Again, various demand models may be incorporated, allowing the inclusion of additional retail variables.	Cohen et al. [4]
3	Simultaneous use of customer, product and inventory information in dynamic product promotion	2018	Retailers can strongly influence customer buying behaviour by employing real-time personalised promotions. This study optimises retail promotions by specifying the optimal mix and pricing of vendor items to include within real-time promotions. The optimal mix and pricing maximise retail profit, given the retailer's inventory levels and the customer's inherent preference towards a particular profit. The authors model the problem as **a mixed-integer nonlinear programming model.**	Mahar et al. [21]

No.	Study title	Year	Summary	Authors()
4	The Impact of Linear Optimization on Promotion Planning	2017	FMCGs sell relatively quickly within retail settings. This study aims to optimise retail promotions by developing **a nonlinear integer programming model** that specifies a single FMCG's price that will maximise profit given specific business rules. The model is modular, as various demand models may be incorporated. A suitable demand model allows retailers to add additional retail variables.	Cohen et al. [8]
5	A retail store SKU promotions optimisation model for category multi-period profit maximisation	2017	This study proposes **a nonlinear integer programming model** that optimises retail promotions at a stock-keeping-unit (SKU) level. The model's goal is to maximise promotional profit over a specific period. The authors show that the level of display and discount depth influence the profitability of retail promotions. As such, the decision variables of the model are whether and how to promote an item and discount depth.	Ma and Fildes [22]
6	Price promotion with reference price effects in the supply chain	2016	Trade promotions are offered by vendors to retailers, vendors offer consumer promotions to customers, and retail promotions are offered by retailers to customers. This study aims to find the discount depth that maximises retail profit, given the effects of trade, consumer, and vendor promotions within retail settings. **A Stackelberg competition** is developed wherein the vendor is the leader, and the retailer is the follower. The optimal discount depth is obtained using backward induction.	Lin [23]
7	Modelling of Product Sales Promotion and Price Discounting Strategy using Fuzzy Logic in a Retail Organization	2016	This study proposes a holistic strategy that maximises the profit obtained by retailers through promotions. **A nonlinear programming model** is developed that specifies the optimal order quantity of a retailer, given the effects of trade rebates. Finally, the authors deploy heuristic methods to determine the discount rate of a retailer to maximise profit.	Kumar et al. [24]

No.	Study title	Year	Summary	Authors()
8	Pricing and Ordering under Trade Promotion, Brand Competition and Demand Uncertainty	2016	Off-invoice-, scan-back-, and buy-back policies are common forms of vendor funding. Off-invoice policies are discounts vendors offer to retailers' orders in return for meeting purchasing targets. Scan-back policies are discounts vendors offer retailers in return for meeting sale targets. Buy-back policies allow retailers to resell unsold stock back to vendors. This study incorporates the effects of these policies within **a nonlinear programming model**. This model aims to find the product price that maximises retail profit from promotions.	Tsao [25]
9	Redesigning promotion strategy for e-commerce competitiveness through pricing and recommendation	2015	Electronic retailing (e-tailing) platforms often recommend products other than those listed to customers during promotions, as customers are more likely to purchase these when the listed item is discounted. This study proposes **a nonlinear programming model** that maximises overall e-tailer profit by specifying the optimal discount depth of the listed product and the mix of other products to recommend during promotions.	Jiang et al. [26]
10	Enhanced joint pricing and lot-sizing problem in a two-echelon supply chain with a logit demand function	2014	The frequency- and size of orders and the retail price significantly influence the combined profit of a vendor and a retailer. This study proposes **a nonlinear integer programming model** wherein these factors are decision variables. The model's objective is to maximise the combined profit of the two-echelon supply chain. The model allows retailers to set prices below cost. In doing so, the model optimises retail promotions.	Yaghin et al. [27]

3.1 Research question 1: How many studies aim to optimise retail promotions using mathematical modelling?

The review protocol identified ten studies published between 01 January 2013 and 6 November 2022 that aim to optimise promotions using mathematical modelling.

3.2 Research question 2: What optimisation approaches do the studies follow?

Table 3 lists the optimisation modelling- and solving approaches used within each identified study.

Table 3: Modelling approaches deployed within the identified studies

No.	Author(s)	Modelling approach	Solving approach
1	Dolat-Abadi [20]	Stackelberg competition	Backward induction
2	Cohen et al. [4]	Nonlinear programming model	Linearisation
3	Mahar et al. [21]	Nonlinear programming model	Metaheuristic
4	Cohen et al. [8]	Nonlinear programming model	Linearisation
5	Ma and Fildes [22]	Nonlinear programming model	Metaheuristic
6	Lin [23]	Stackelberg competition	Backward induction
7	Kumar et al. [24]	Nonlinear programming model	Heuristic
8	Tsao [25]	Nonlinear programming model	Heuristic
9	Jiang et al. [26]	Nonlinear programming model	Heuristic
10	Yaghin et al. [27]	Nonlinear programming model	Metaheuristic

The studies by Dolat-Abadi [20] and Lin [23] model the problem as a Stackelberg competition. Simaan and Cruz [28] describe a Stackelberg competition as an economic game wherein one player, the leader, decides first. In response, another player, the follower, makes their decision. The leader is aware of the follower's decision-making process and can influence it. The optimal strategies for Stackelberg competitions are commonly determined using backward induction. Backward induction involves evaluating each optimal decision from the final to the starting decision node. An action is eliminated if the node's alternatives dominate its terminal node [29]. Dolat-Abadi [20] and Lin [23] follow the backwards induction solving approach.

The remaining studies model the problem as nonlinear programming models, i.e., optimisation problems wherein the objective function or at least one of the constraints is nonlinear [11]. Nonlinear programming problems are generally NP-hard and, thus, difficult to solve [30]. Historically, a popular approach has been approximating a linear equivalent to the problem [31]. Linearisation allows the problems to be solved effectively using algorithms such as the Simplex-, Khachiyan's, Affine Scaling, and Karmakar's method [11]. Cohen et al. [8] and Cohen et al. [4] follow a linearisation approach to solve the problem.

Alternatively, heuristic and metaheuristic methods often provide sufficiently good solutions to nonlinear programs [32]. These methods do not necessarily provide exact solutions. However, heuristics can provide high-quality solutions in a reasonable amount of time by algorithmically exploring the accumulated search experience- and space [33]. Kumar et al. [24] deploy a heuristic based on the Fordyce-Webster Algorithm. Yaghin et al. [27] deploy a particle swarm metaheuristic. Tsao [25] develops a custom heuristic algorithm. Ma and Fildes

[22] deploy a genetic algorithm. Several open-source and commercial solvers are available for solving nonlinear programming problems using autoselected metaheuristic methods [34, 35]. In this regards, Mahar [21] deploys BARON and Jiang et al. [26] deploy the NMaximise routine included in Wolfram's Mathematica software.

3.3 Research question 3: How do these studies model retail demand?

To effectively assist retailers with promotion planning, mathematical models need some framework to forecast customer response to promotional activities. Table 4 summarises how each study accounts for retail demand, given the effects of promotions.

Table 4: Demand modelling techniques deployed within studies.

No.	Study	Modelling technique	Predictors within the demand model
1	Dolat-Abadi [20]	Random demand	N/A
2	Cohen et al. [4]	General nonlinear function	Item price, past prices of items, past prices of substitutes
3	Mahar et al. [21]	General nonlinear function	Discount depth, level of advertising, customers' valuation of an item
4	Cohen et al. [8]	General nonlinear function	Item price, past prices of item
5	Ma and Fildes [22]	Autoregressive distributed lag model	Discount depth, level of advertising, past sales, and whether a special occasion is taking place.
6	Lin [23]	Linear function	Item price
7	Kumar et al. [24]	Moving average model	Past sales
8	Tsao [25]	Linear model	Item price, customers' brand loyalty
9	Jiang et al. [26]	General nonlinear function	Item price, discount depth, customers' valuation of item and substitutes
10	Yaghin et al. [27]	Logistic regression model	Item price, price sensitivity of item, market size

The techniques that are deployed vary in complexity. The study by Dolat-Abadi [20] assumes that demand is random. The studies by Lin [23] and Tsao [25] deploy linear regression. More advanced statistical learning methods, such as the autoregressive distributed lag model developed by Ma and Fildes [22], are also used. The study conducted by Yaghin, et al. [27] uses a logistic regression model as the primary demand forecasting tool, while Mahar, et al. [21] include logistic regression predictions within a more advanced nonlinear function.

The label *general nonlinear function* is given to all miscellaneous modelling techniques. Jiang, et al. [26] and Mahar, et al. [21] use mathematical analysis to arrive at custom equations to express the probability of customers purchasing an item. Other studies that fall under this label exploit widely accepted retail equations. The studies conducted by Cohen, et al. [36] and Cohen, et al. [4] use the log-log relationship to reflect the relationship between sale price and demand. Kumar, et al. [24] use a moving average forecasting method to predict sales.

The demand models used within the literature also vary in the predictors included. The pie chart in Figure 1 indicates how often each predictor was included within the demand models.

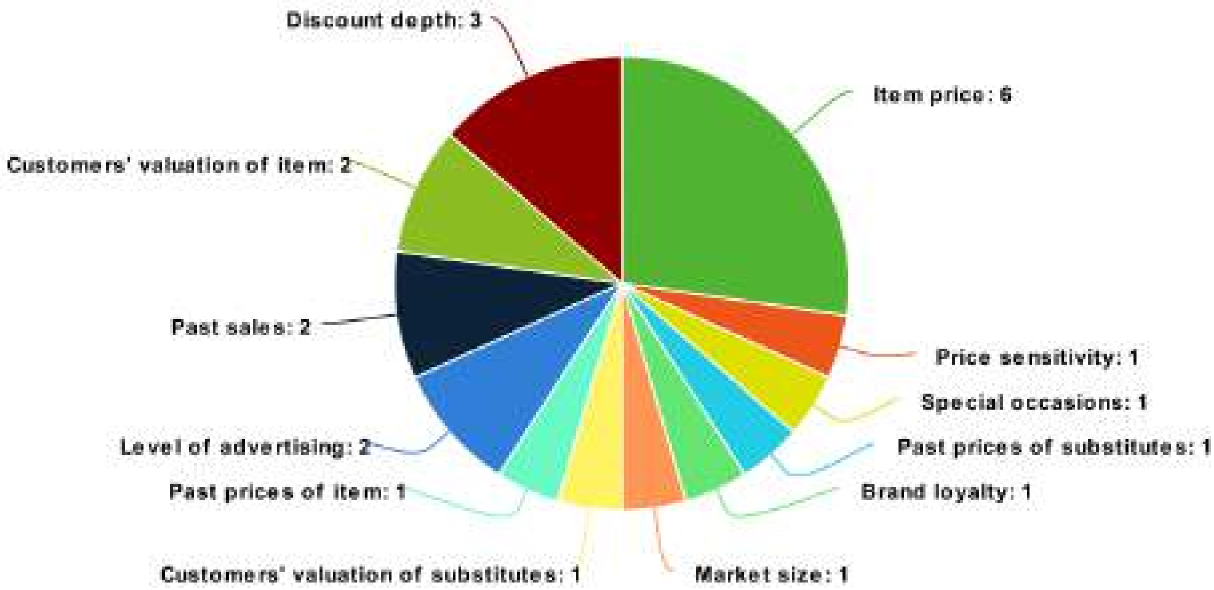

Figure 1: Pie chart of predictors within the demand model

Item price was the most common predictor, occurring in six out of ten studies. The reason for this inclusion is evident, given the strong relationship between item price and demand [32]. For the same reason, discount depth is the second most common predictor within the demand models, occurring in three out of ten studies. Other predictors occurring in multiple studies are the customers' valuation of an item, past sales, and the level of advertising. Seven out of the twelve predictors occur in only one study.

This diversity in demand modelling techniques and the predictors indicates that there is no universally applicable method to incorporate customer demand into mathematical models that assist retailers with promotion planning.

3.4 Research question 4: What common retail effects do these studies address?

Table 5 summarises the retail variables the models include, as identified in this paper's introduction. Own-promotional effects refer to the effect that its promotion has on its sales. Cross-promotional effects refer to the effect that the promotion of an item has on the sale of other items. Stockpiling effects refer to the effect that the promotion of an item has on its long-term sales. Vendor funding refers to additional revenue streams a vendor provides to a retailer in return for promoting their items.

Table 5: The occurrence of common retail effects within the studies

		Effects			
No.	**Authors(s)**	**Own-promotional**	**Cross-promotional**	**Stockpiling**	**Vendor funding**
1	Dolat-Abadi [20]	✓	×	×	×
2	Cohen et al. [4]	✓	✓	✓	×
3	Mahar et al. [21]	✓	✓	×	✓
4	Cohen et al. [8]	✓	×	✓	×
5	Ma and Fildes [22]	✓	✓	✓	×
6	Lin [23]	✓	×	×	✓
7	Kumar et al. [24]	✓	×	×	✓
8	Tsao [25]	✓	✓	×	✓
9	Jiang et al. [26]	✓	✓	×	×
10	Yaghin et al. [27]	✓	×	×	✓

To be included in this review, a mathematical model must determine the optimal promotional price at which to sell an item. All mathematical models under investigation, therefore, include the effects of own-promotion. Following this effect, cross-promotional- and vendor funding effects are most included, appearing in half of the identified studies. Only three studies include the effects of stockpiling. While the mathematical models each address some combination of these effects, no single model simultaneously addresses own-promotional, cross-promotional, stockpiling, and vendor funding effects.

3.5 Research question 5: What gaps exist within the literature?

Table 6 lists the limitations and future recommendations of each identified study. Most of the recommendations are study specific. Multiple authors, however, recognise the accuracy of the demand models as a shortcoming. This is the case for the studies by Yaghin, et al. [27], Ma and Fildes [22], Jiang, et al. [26], and Mahar, et al. [21].

Table 6: Future recommendations identified by study authors

No.	Author(s)	Self-identified research gaps
1	Dolat-Abadi [20]	The study can be expanded to include multiple vendors who compete with each other in terms of investment. Industry mechanisms such as payment delays and vendor funding effects could be included. Retailers may invest in fresh-keeping activities as well. The model can be expanded to include this variable.
2	Cohen et al. [4]	Not stated.
3	Mahar et al. [21]	The cost of changing the active promotion may be incorporated as a model parameter. The assumption that the customer only purchases a single product could be dropped. The demand model can be enhanced to include price sensitivity effects.
4	Cohen et al. [8]	The model should be validated by conducting a pilot expiring where the model is applied to a real-world retail setting.
5	Ma and Fildes [22]	The model can be expanded to include additional retailers. The effects of ordering- and stocking costs can be included. The demand model can function even in the presence of limited input data. Computational issues concerning the use of the genetic algorithm can be resolved.
6	Lin [23]	The retailer and vendor's joint pricing and promotion decisions may be explored. Promotion duration can be incorporated as a decision variable.
7	Kumar et al. [24]	The model may include multiple suppliers, retailers, and product categories. Additional parameters may be incorporated, such as back-orders and transportation costs. The computability of the model can be improved.
8	Tsao [25]	The model can be expanded to include brand and retail competitions. The effect of other forms of trade promotions can be investigated.
9	Jiang et al. [26]	The model can be enhanced to cater specifically to brick-and-mortar retailers. The model can be made to consider the impact of network congestion on profitability. Additionally, it can incorporate the influence of product quality on service duration. Moreover, there is room to enhance the demand model.
10	Yaghin et al. [27]	The model can include multiple demand classes and vendors. The model can incorporate stochastic elements. Other convexification and modelling strategies may be explored to improve the computability of the model.

Additionally, multiple authors recognise computability issues with nonlinear programming models, even when using heuristics and metaheuristics in their solving. This is the case for the studies by Yaghin, et al. [27], Ma and Fildes [22], and Kumar, et al. [24].

However, the central gap within the literature is apparent, considering that the effects of cross-promotional, stockpiling, and vendor funding are significant to profitability. The previous research question indicates that no mathematical model within the scope of this SLR simultaneously accounts for these effects.

With this said, depending on the mathematical model's objective, excluding some combination of the abovementioned effects may be appropriate. For example, the goal of the mathematical model by Dolat-Abadi [20] is to minimise fresh agricultural product waste. The effect stockpiling has on this goal may be insignificant. This study does not posit the ineffectuality of a mathematical model that disregards some of the effects. Instead, it advances the notion that to maximise promotional profit, the incorporation of all the effects is imperative.

4 FINDINGS AND CONCLUSIONS

Promotions can be highly beneficial to retailers; however, the contrary may also be true in some instances, as several adverse effects accompany them. This makes the planning of profitable promotions complex. In response, multiple mathematical models have been developed to assist retailers with promotion planning.

An SLR is conducted following an established methodology to identify these studies and to evaluate them in terms of the modelling approaches deployed and their limitations. In doing so, this paper provides a valuable contribution to research by providing a comprehensive summary of the existing mathematical models used in retail promotion planning.

The SLR indicates that ten studies have been published since 2013 that aim to optimise retail promotions. These studies exclusively model the promotion optimisation problem as either a Stackelberg competition or a nonlinear programming model. The Stackelberg competitions are solved using backward induction. The nonlinear programs are solved using heuristics and metaheuristics or linearised and solved using conventional methods. The demand modelling approaches deployed vary in complexity and the included predictors.

Multiple authors report, however, that their demand models' applicability limits the optimisation models' usefulness. Multiple authors also express difficulty in solving nonlinear programming models. Finally, none of the identified studies address the combination of variables significantly influencing retail promotion profitability.

5 FUTURE WORK

This study reveals a research gap where no model has been identified that simultaneously addresses cross-promotional, stockpiling, and vendor funding effects. In addition, solvability issues and shortcomings within the demand models deployed by multiple existing promotion optimisation models limit their usefulness.

This means that within the scope of this study and to the authors' best knowledge, no existing mathematical model can fully optimise promotions. It is recommended that future research focuses on the development of mathematical models that simultaneously includes the effects of cross-promotion, stockpiling and vendor funding. Concurrently future models must accurately account for retail demand whilst retaining solvability. Developing mathematical models that meet these requirements provides a challenging task for future researchers but is crucial for enhancing the promotion planning strategies of retailers.

ABSTRACT

Local Government Vehicle Fleets (LGVFs) are an essential component in the running of municipalities. Their asset portfolio is well over hundreds of millions to billions of Rand, making them critical assets in the running of municipalities. The purpose of this study is to assess the impact of administrative delays on the overall downtime experienced in LGVFs. The scope of downtime for this study is for activities related to services and repairs. A review of literature focused on the LGVFs usage as well as unpacking the business processes associated with the flow of work management activities. Potential areas where delays could be experienced were identified while the impact of downtime was also elucidated in terms of cost, fleet size and other metrics. The conclusion is that there is a need to equip policy makers with a framework that will balance statutory and policy compliance and running the LGVFs optimally.

Keywords: Vehicle Fleets, Downtime, Municipalities

1 INTRODUCTION

Vehicle fleets in local governments are vital assets by which municipal services such as electricity, water and transportation are delivered. Various municipalities and cities in South Africa manage thousands of vehicles such as City of Cape Town (CoCT) which has an active fleet of approximately 7 000 vehicles [1] worth billions of Rand. This makes vehicle fleet assets a critical asset portfolio which must be managed optimally if maximum value is to be derived from them.

In the management of vehicle fleets, downtime can be divided into two categories: scheduled downtime, which includes planned services and repairs, and unscheduled downtime, resulting from unforeseen circumstances like breakdowns and accidents. Fleet downtime can be attributed to many factors and some experts in Local Government Vehicle Fleets (LGVFs) postulate that administration delays contribute a significant portion to downtime compared to the actual repair time [2]. However, no study has definitively determined the extent of this contribution. Other studies have shown that in fleets, unscheduled downtime can also be attributed to other extreme factors such as climate and natural conditions which human intervention can hardly control [3].

LGVFs play a crucial role in providing essential services to residents and employees of municipalities, including transportation, security and law enforcement, emergency services, water, electricity, and waste collection. These fleets serve various core functions such as refuse removal from residential areas and industrial sites, transporting people to their places of residence, work, or business, providing emergency services like fire engines, facilitating law enforcement activities, and enabling service delivery such as water and electricity projects, servicing, and repairs. Municipal environments often require specialized vehicles to perform these functions [4].

The availability of LGVFs is crucial for municipalities and cities. When these assets experience downtime, there can be significant consequences. Residents may struggle with commuting and waste accumulation and interruptions in essential services like electricity, water, and sanitation can raise security and health risks. Delayed emergency responses can lead to property damage and loss of life, while insufficient law enforcement visibility may lead to increased crime. Idleness among municipal employees and a backlog of service requests can occur without access to vehicles. Fleet managers may face pressure to acquire additional vehicles to compensate for downtime.

Managing the downtime of LGVFs and the repairs and maintenance (R&M) process is thus necessary to ensure reduction in downtime related costs and optimising vehicle fleet size. Some municipal managers have argued that in trying to mitigate effects of downtime, municipalities end up being inefficient by mitigating effects of downtime through purchase of extra vehicles [2]. For example, for a fleet of 7 000 vehicles, a fleet operational availability of 75% translates to an average of 1 750 vehicles off the road every day, which would be costly to the municipality and the residents.

The importance of functionally available fleets cannot be overemphasized. Therefore, this study puts focus on reviewing elements that affect LGVFs downtime and ways in which this impact can be reduced using available literature. This research will contribute value adding literature for analysing downtime categories. Most importantly, it will unpack administrative bottlenecks in procuring R&M services for LGFVs and review all elements that exacerbate downtime.

2 DOWNTIME

Downtime is the state in which an asset is unavailable to perform any work. This can be through planned downtime for scheduled services or unplanned downtime in which an unexpected undesirable condition or breakdown forces a maintenance intervention to be executed.

2.1 Downtime in Vehicle Fleets

In vehicle fleet management, downtime can be categorised into scheduled downtime for planned services and repairs, as well as unscheduled downtime due to unforeseen circumstances. Fleet downtime can be attributed to many factors and some who have experience in LGVFs postulate that administrative delays contribute a significant portion [2], however there is no study that clearly determines to what extent this is. Another study has shown that in fleets, unscheduled downtime can also be attributed to other factors such as climate and natural conditions which human intervention can hardly control [3].

2.2 Factors affecting Downtime

There are several challenges that contribute to prolonged downtime in vehicle fleets [3], [5], [6].Some of the issues are listed below:

2.2.1 Vehicle age – generally older vehicles experience prolonged downtime periods and fail more frequent than newer vehicles.

2.2.2 Vehicle usage such as running hours or mileage – high mileage vehicles tend to experience more downtime than those that have low usage because of the frequency with which original equipment manufacturer (OEM)'s usage-based maintenance requirements are reached.

2.2.3 Operating conditions such as weather and climate – in environments that experience harsh conditions such as extreme cold, heat or humidity, some vehicles become inoperable.

2.2.4 Administrative delays in authorisation of repair or servicing work – downtime can be prolonged due to compliance to policy or statutory requirements. Some of these requirements make it mandatory to advertise for services to be rendered for a certain minimum period.

2.2.5 Outsourced service providers' inefficient processes – service providers can prolong downtime due to their inefficient process such as delays in purchasing spare parts to execute the repair work.

2.2.6 Lack of real time status updates and feedback from service providers – LGVFs can experience prolonged downtime because of poor communication. A service may have been completed but if local government officials are not notified on time, the downtime will be extended.

2.2.7 Information not readily available when required such as vehicle model and warranty information can cause delays in getting quotations and procurement of parts.

3 WORK MANAGEMENT PROCESS

Maintenance Work Management is the process of properly managing the maintenance work using work orders from planning to receiving the feedback of completed work.

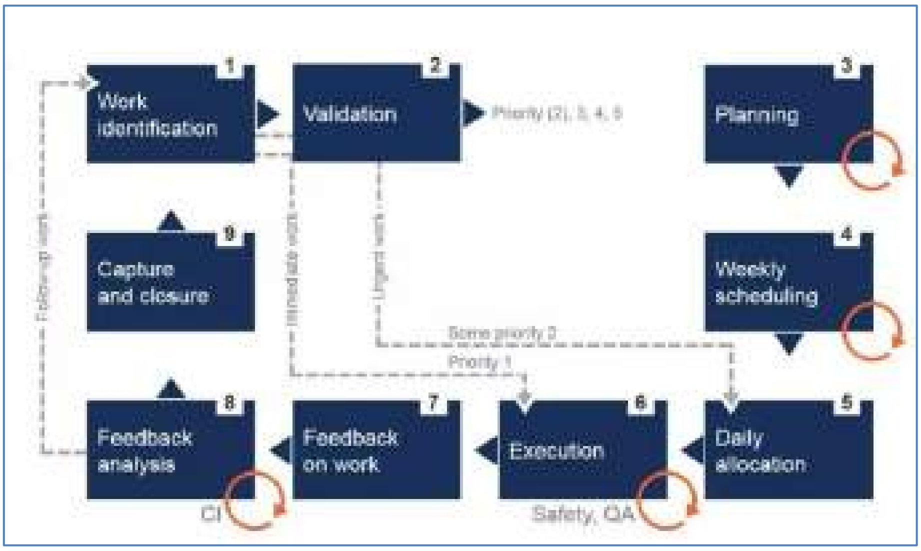

Figure 1: Work Management Process: Adopted from Pragma [8]

Pragma, a leader in the Physical Asset Management (PAM) field, recommends a work management process detailed in Figure 1. When one applies this process to a fleet environment, downtime can be prolonged in certain steps as discussed below.

3.1 Work Identification[1] – LGVFs are complex in the sense that work can only be identified after diagnostic tests are done to find out what work will be required. However, a high-level work identification process is imperative to determine which service providers should be used for different requirements such as engine, body, tyres, auto-electrical system, and ancillary equipment such as hydraulic system.

3.2 Validation[2] – for the work process to be initiated there must be a work order from a requester. This work is then validated by a designated official to determine if the work is indeed what is required.

3.3 Planning[3] – this process is important to determine which (trade) does the work, when the work is to be done, spare parts required, tools required and estimated cost of the work. In LGVFs this process is where downtime may be prolonged as certain policy steps and compliance to statutory and legal requirements must be adhered to. For example, according to City of Cape Town's SCM policy section 299 [12], for any transaction value between R10 000 and R200 000, a minimum of 3 quotations must be supplied. Section 302 of the same policy also demands that quotations which are likely to be above R30 000 must be advertised for at least seven days. These processes inherently prolong downtime periods, and thus it is important to investigate to what extent they are affecting LGVFs availability.

3.4 Scheduling[4] - In vehicle fleets, maintenance scheduling is the process of organising when a vehicle is to be sent for a maintenance intervention. This works hand in hand with the planning function which determines who will perform the maintenance intervention, what parts they will require, the estimated costs and durations [11]. The challenge which comes with this is that different components of the vehicle such as tyres and brake pads deteriorate at different intervals [17].It is thus important to find an optimum period that ensures that all components are checked and repaired in order to reduce downtime.

R&M process for LGVFs involves administrative checks and controls to ensure that the repairs are done within the statutory frameworks. It can take up to weeks for authorisation of minor repairs or purchase of spares for major repairs and more delays are incurred in the process due to the additional administrative processes that must be followed [2]. Extra levels of authorisations are required for associated or additional costs to conform to the Municipal Finance Management Act (MFMA) which all municipalities must adhere to [7]. A study showed that more than 80% of downtime of vehicles undergoing a service or repair, is not related to the actual time spent servicing, or repairing a fleet vehicle [5] and it is imperative to get an accurate perspective for LGVFs. LGVFs also have their own workshops for internal repairs of vehicles. These facilities are sometimes not viable because of the mix of vehicle types and or low volumes of vehicles brought in for repairs [2]. In conclusion the work management process has elements that are prone to extend LGVFs downtime if no proper controls are in place,

4 PROCUREMENT AND ASSET MANAGEMENT

The Municipal Finance Management Act 56 of 2003 (MFMA) "intends to secure sound and sustainable management of the financial affairs of the municipalities and other institutions in the local sphere of government…" [7]. The Act sets out a framework of how financial processes are managed in the local government environment including managing the R&M of LGVFs. The procurement process can be summarised into 8 stages of which LGVFs are aligned to for procuring services for R&M. In between these processes, potential delays exist especially when managing fleet sizes of up to thousands of vehicles.

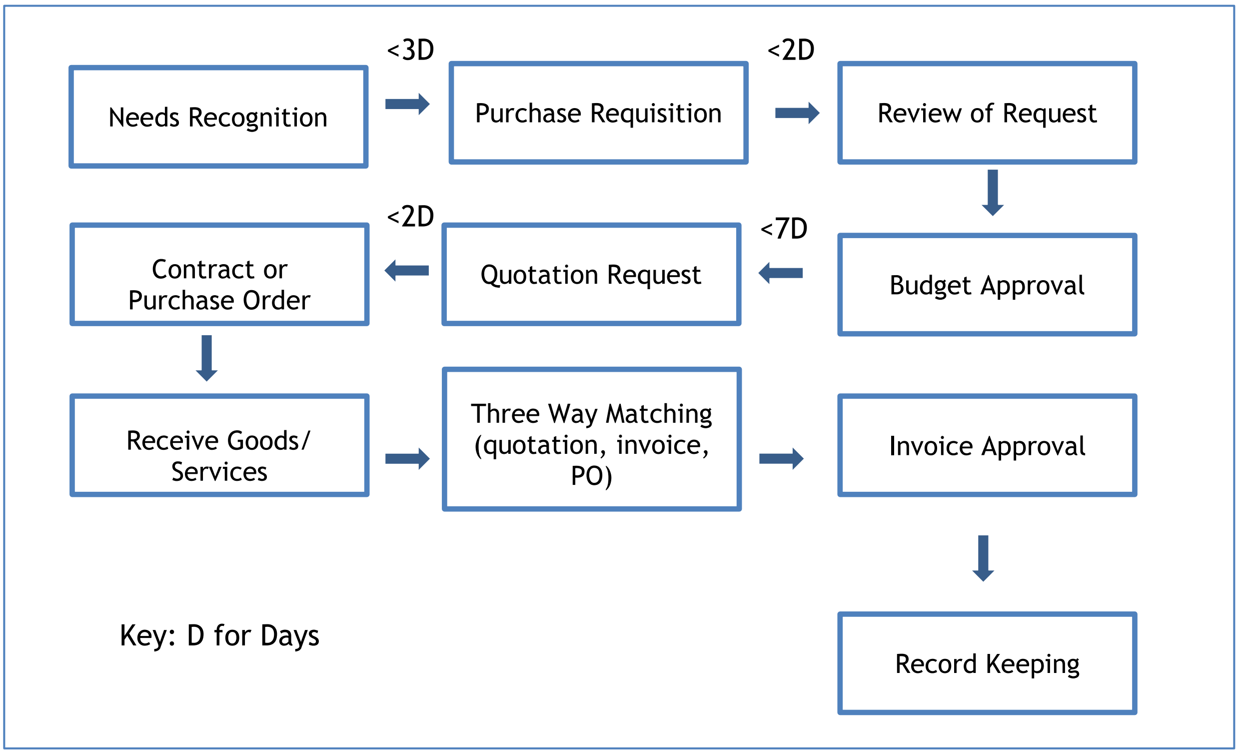

Figure 2: Procurement Process: Adopted from Kissflow Procurement Cloud [13]

The procurement process has different role players that are involved from initiating a maintenance activity to execution as shown above. There are certain processes that must be completed within benchmarks set in days as shown in Figure 2, however enforcement of such benchmarks can be challenging for municipal environments processing thousands of work requests per month. Depending on the estimate cost of a work request, budget approval and purchase order issuance can be prolonged to conform to certain policy guidelines.

4.1 Unauthorised, irregular, or fruitless and wasteful expenditure

Section 32 of the MFMA puts liability on municipal officials for any subsequent “Unauthorised, irregular or fruitless and wasteful expenditure” [7]. This liability results in checks and balances being implemented within the local government to ensure all expenditure is duly authorised and analysed to be not fruitless or wasteful.

Fleet assets are not spared in that whenever services are needed for R&M of the vehicles, the same process applies regardless of urgency. In effect a repair for R3 000 will undergo the same administrative processes and authorisation as that for R50 000.

4.2 Goods and services procurement

Local governments have policies that should align to the Section 111 of the MFMA [7]. These policies govern the processes of tendering, quotations, auctions etc. which in this study, affects the execution of repairs and maintenance work on Fleet Assets [12].

4.3 Supply chain management (SCM) policies

To align with the MFMA legislation councils have adopted SCM policies for the implementation of procurement processes [7]. Written price quotations are required for transaction values between R2000 and R10 000 [12]. For transactions between R10 000 and R200 000 formal written price quotations are required and for transaction values that are more than R200 000 competitive bidding processes are required [12]. All these processes add layers of administrative processes that can potentially cause delays for large fleets, as hundreds of quotations and requisitions are potentially handled daily.

4.4 General conditions of contract

All the SCM policies have a section on the general conditions that a bidder must meet to be considered to offer any services to municipalities. The following are some of the critical things mentioned by the policy [12].

- Tax reference number
- VAT registration number
- Valid tax clearance certificate

If a service provider is the sole supplier for a particular service and their tax affairs are not in order, this can result in unnecessary downtime being incurred. These requirements are checked every time work is allocated to a particular contractor.

5 LIFECYCLE VALUE REALISATION

Lifecycle value realisation (LVR) has to do with different methodologies that are utilised in making sure that the “best total value” is released throughout the lifecycle of an asset [14]. This begins from the acquisition of the asset, utilisation of the asset, maintenance etc. in realisation of the objectives of an organisation [14]. The study aims to ensure that value is realised from LGVFs assets during their lifecycle by cutting down maintenance cost in terms of the downtime period [11].

5.1 Asset management decision making

The importance of asset management decision making is to maximise the value realised from an asset during its life [15]. This study focused on the challenges faced during the operation and maintenance of an asset and the associated decision making. The way an asset is operated and maintained affects the costs associated with that asset [15] and achievement of an organisation’s objectives. Therefore, this study was well within the scope of the Group 2 of the 39 GFMAM subjects.

5.2 Benchmarks

There seems to be NO industry standards on availability levels for fleet assets, however an online article pegged a benchmark of 95% [16]. Several issues affect attainment of high levels of fleet availability including vehicle types mix, spare part management, vehicle age and condition and other factors. Some of the benchmarks related to fleets include schedule attainment for planned scheduled tasks, tactical work (planned) vs non-tactical work (unplanned) ratio, technician productivity and other metrics [18]. These benchmarks help gauge the performance of the fleet and the management practices.

6 COSTS ASSOCIATED WITH DOWNTIME

LGVFs are diverse fleets and certain vehicle types are more challenging to manage than others. These include vehicles with hydraulic systems mounted on them such as aerial platforms, cranes and waste compactors. When these vehicles are unavailable, there are direct and indirect costs associated with their downtime [17][5] such as;

- towing fees in the event of breakdowns,
- rental of substitute vehicles,
- overtime for technicians for cases of internal workshops,
- service delivery compromised
- If short term rentals are not available, work crews will be underutilised
- Inflating fleet size to compensate for downtime
- Insurance, licensing and R&M costs.

It is important to explore the contribution of the workmanship of the service providers to the overall downtime of the vehicles. If the workmanship of the repair work or servicing of the vehicles is poor, then it will lead to more frequent breakdowns and hence an increase in downtime.

6.1 Total downtime cost

The impact of downtime can be quantified in terms of downtime cost which will be discussed in this section. For one to truly be able to determine this cost, certain information must be available and accurate. Tabikh carried out a survey on manufacturing companies in Sweden and the conclusion was that 87% of the surveyed companies did not have a model of quantifying the downtime cost [9]. Fitchett emphasizes the importance of recording the actual times of a downtime occurrence [10]. This is done through the work order management process, and often the “started on” and “completed on” dates and times must be populated to give the accurate downtime period. However, there is research that shows that most organisations do not fully utilise their work order systems or enterprise resource planning (ERP) systems with the procedures being by-passed sometimes [10]. To accurately track downtime, it is important to put in place and follow procedures to ensure the ERP systems have adequate information. When this is done, downtime can be accurately tracked with the end goal being to reduce it.

A lot of methods utilised for reporting, describe downtime as the period when a maintenance intervention take place [10]. However, this is not the true reflection of the downtime period; the downtime starts from when the failure occurs and the asset cannot be utilised. Applying this to LGVFS, downtime is from when a vehicle is unable to function as desired rather than when it is taken for service or repair, or dropped at a service provider’s premises. Due to delays of procuring parts and or getting authorisations from delegated local government officials, “started on” date of the maintenance intervention is not necessarily the date the vehicle is brought in for maintenance intervention or when the vehicle became inoperable.

Depending on the industry, a downtime cost is calculated based on certain criterion such as production cost, amount of scrap due to the downtime, cost of reduced production and other measures [10]. In LGVFS the downtime cost can be best calculated by the following factors

6.1.1 Hiring costs of vehicle in the same class: For continuity of business the department may be forced to hire another vehicle of the same class. This extra cost then becomes part of the downtime cost, and as the downtime is prolonged, the greater this cost becomes.

6.1.2 Unutilised Labour: In the event of no alternative hiring arrangements available, it can be calculated in terms of cost of labour that becomes idle for that downtime duration. For example, a vehicle utilised by two people and is unavailable for 8 hours; one can quantify downtime cost in terms of 16 labour hours multiplied by the labour rate of the corresponding employees who become idle.

6.1.3 Lost Revenue: If a particular vehicle is used for economic activity that directly brings income to the municipality such as My-Citi buses which transport personnel every day, the downtime cost can be quantified in terms of opportunity cost of potential revenue. For example, if the bus transports on average 30 people per hour and is down for 10 days, the cost can be estimated by multiplying these variables by the cost per trip minus the running costs.

6.1.4 Overtime: Other LGVFs vehicles are used for essential services that must be provided regardless of status of the availability of vehicles. For water and sanitation services such as solid waste management, refuse must still be collected even when fleets are facing challenges. In such circumstances overtime is accrued to cater for delays caused by downtime and this can then be categorised as part of downtime cost.

6.1.5 Oversized fleet size: The greatest downtime cost is manifested on the fleet size for fleets experiencing high downtime percentages. To mitigate effects of downtime, the fleet is oversized to compensate for inefficiencies. For example, a fleet of 1 000 vehicles operating at 60% availability without any need for outsourcing may be said to be oversized. If an availability target of 85% is achieved this can result in fleet size being optimised to for example 850 rendering the other 150 of no use. One can argue in this case the downtime cost to be the replacement costs of the 150 ‘extra’ vehicles which can approximate more than R200 million for specialised vehicles.

The intent of knowing and quantifying downtime costs is to mitigate its effects through reduction of downtime. Significant savings can be accrued from knowing all factors contributing to downtime and dealing with them decisively. Due to interventions that were instituted at one manufacturing facility, savings of 10 minutes per day could be realised which translates to up to 50 hours a year and a cost of more than R5,4 million [9]. Applying the same principles to LGVFs can result in significant savings to local governments through reduced downtime, optimising fleets size and deferring capital expenditure.

7 METHODOLOGY

In the literature review, four major topics were covered which are downtime, work management, procurement process and the downtime costs. An integrative literature review method was used with the aim of assessing the literature on the topic of downtime, specifically in LGVFs [19].

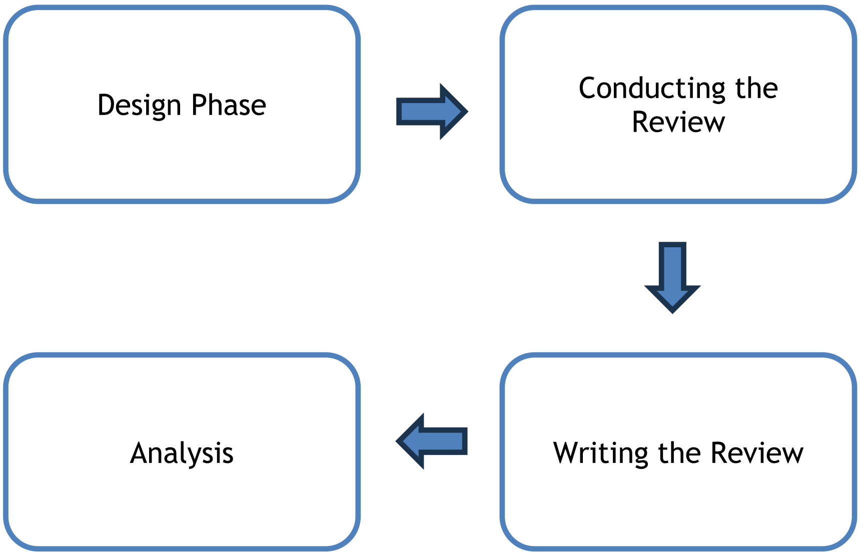

Figure 3: Integrative Review Process

The aim of the study was to gain insights into what constitutes downtime in LGVFs and how the environment they operate in, affect the downtime they experience. The approach was to review literature on the major topics as stated and those were the terms used in searching for articles. For downtime, a different variation of unavailability was used as well as searching for articles related to availability. Other search terms that were used are downtime cost, cost of downtime, vehicle fleets, procurement process and fleets.

More than 100 papers were reviewed on two search engines, google scholar and sun scholar which gave access to different journal and conference publications. However less than 20 articles were used as there is limited information in this research area. It must be noted that outside this review, a case study will be conducted on one of the major municipalities in South Africa to assess quantitatively the impact of administrative delays on the downtime experienced in their LGVFs and to quantify the downtime costs associated.

8 DISCUSSION

After a comprehensive review of literature relating to downtime, the conclusion is to a large extent, administrative processes prolong the downtime experienced in LGVF, to a degree that will be determined in a case study. Webb [2] an experienced manager in the local government industry has claimed that in fact, the portion of downtime related to administrative processes is greater than 50%, however this was not backed by any data but mere experience. In as much as this may be true it is important that a scientific method is followed to make this claim.

However, from the review of the MFMA legislation and certain supply chain policies of some municipalities, there are inherent procedural delays that cause downtime to be exacerbated. If the policy states that an advertisement requesting for quotations should be seven days, then the LGVFs assets will have to stand for that period, thereby increasing downtime. In such cases downtime will tend to increase, however this must also be backed up by scientific data to verify what percentage of work request get advertised for such long periods and what impact it has on the downtime.

The work management process must also be streamlined to ensure that planning and execution is optimised thereby reducing downtime. Downtime is influenced by the planning process with delays or inefficient planning having a negative impact on the availability of the LGVFs assets. A case study will give insights into how efficient the planning process is in LGVFs and how other role players responsible for administrative processes are effectively performing their functions.

To make a case to policy makers to adjust policy or legislation, it was important that downtime cost be expanded on. The literature provided different ways in which downtime costs can be quantified in relation to hiring cost, unutilised labour, bloated fleet size and other costs. This is imperative to make a comparative analysis of average downtime cost incurred against the thresholds set out in policies. For example, incurring a downtime cost of R18 000 for an approval of R10 000 is not economical and hence a case can be made either to adjust advertising periods or increase thresholds that require prolonged advertising periods, to reduce the downtime incurred.

9 CONCLUSION

Review of literature has established that there are administrative processes that have an influence in the downtime that is experienced in LGVFs. The MFMA set up a legislative framework that must be adhered to in procuring goods and services while the SCM policies also set out the process to be followed in this regard. As discussed, it is to a large extent inherent in the process that delays will take place to an extent which will be investigated in a case study. The policies that are enforced are meant to ensure that municipal resources are not wasted, however the hidden costs associated with downtime do not seem to have been considered in coming up with policies, which could result in more costs being incurred due to downtime, than what is intended to be saved.

ABSTRACT

Goal-12 of the 17-sustainable development goals is focused on responsible consumption and production of products and services, and its targets include reducing waste generation through prevention, sustainable management and efficient use of natural resources. This study aims to explore the impact of quality management practices on sustainable wheat-flour milling. A quantitative research approach was collected through a self-distributed and online questionnaire. QMPs, such as 6-sigma practices, 5S practices, quality management system implementation and process management, were found to be affected by factors, such as organisational culture, workforce management and leadership support and commitment thereby affecting product quality and financial sustainability of the organisation. The results of the study indicate that organisational culture, workforce management and leadership support and commitment in the wheat-flour milling organisation are indeed factors that management should consider when QMPs are being considered.

Keywords: Total quality management, organisational performance, customer satisfaction, customer focus, continuous improvement

* Corresponding Author

1. INTRODUCTION

The heart of the matter is that the sustainability of all organisations depends on their ability to deliver high quality products to meet and exceed customer expectations. Therefore, organisations adopt strategies such as quality management to achieve that. The Wheat-Milling industry contributes greatly to the global economy and thus QMPs are of high importance in the wheat milling industry. The focus of this study is to examine the impact of QMPs on the sustainability of wheat-flour milling business. This paper will lay down the background of the study, research problem, research questions, research objectives, population and sample framework, data collection and analysis, as well as the ethical considerations in the study. This study is important, as it exposes the factors that affect QMPs and more importantly identifies the most significant quality management practice that influences rework. Lastly, it provides recommendations on how to improve QMPs.

2. BACKGROUND TO THE STUDY

One of the major global bottlenecks to sustainability in the manufacturing industry is product waste that requires reworking [1]. Most manufacturing organisations throw away non-conforming products to avoid the rework process, as rework costs are high [1]. This is a global challenge, as waste not only has a great impact on the environment but also on the economic and social aspects of the triple-bottom-line. In the South African wheat-milling industry, most of the waste goes back to rework and very small quantities of this waste go to animal feed. Even though wheat flour can be reworked, the rework costs are high. There is a growing engrossment in the flour milling industry because of its great impact on global economic changes, as well as its great role in boosting the South African economy. Moreover, South African wheat-flour milling organisations have opted to utilise quality management programme to strengthen their competitive advantage so as to overcome unexpected business difficulties and threats that may arise. Nevertheless, the execution of quality management for most organisations is lower than the expected level, and this has a great negative impact on the sustainability of organisations [2].

3. RESEARCH PROBLEM

The research organisation is faced with problems of high non-conformances and defects due to poor quality products, contamination and infestation. Defects can result in severe loss in terms of costs, reputation or project failure. [3] agree with [2] by saying that defects harm delivery times, costs and quality of products and by deleting these wastes, organisations in the manufacturing industry can increase their profits. However, [4] believe that defects not only impact costs but also production throughput. Higher defects lower manufacturing yields and the quality of products and lead to reliability problems. The failure of organisations to get to the root causes of these defects results in high costs for rework [5].

3.1 Problem statement

QMPs are an essential part of any organisation. High rework volumes due to defects impacts organisational financials and sustainability. The triple bottom-line aspects of sustainability cannot be achieved without successful implementation of these practices. The organisation has been experiencing high rates of rework and losses leading to poor financial results. Therefore, which QMPs are most relevant in the wheat flour milling organisation.

3.2 Research questions

- What are the factors that influence QMPs in the wheat-flour milling organisation?
- What is the most significant quality management practice that influences rework at the wheat-flour organisation?
- Which recommendations can be provided to improve QMPs at the wheat-flour milling organisation?

3.3 Hypotheses developed for the study.

The following hypotheses have been developed for this study:

Table 1: research questions related to hypotheses.

Research question	Hypothesis
What are the factors that influence QMPs in the wheat-flour milling organisation?	• H_1 QMPs have a direct impact on organisational performance.
What are the factors that influence QMPs in the wheat-flour milling organisation?	• H_2 QMPs have an impact on product quality.
What is the most significant quality management practice that influences rework at the wheat-flour organisation?	• H_3 Leadership commitment and support have an impact on the implementation of QMPs .
What is the most significant quality management practice that influences rework at the wheat-flour organisation?	• H_4 Organisational culture has an impact on QM practices.
What is the most significant quality management practice that influences rework at the wheat-flour organisation?	• H_5 QMPs have an impact on business sustainability.

4. LITERATURE REVIEW

4.1 Introduction

Despite several publications evidenced by [6,7,8,9,10] the correlation between QMPs and organisational performance in the manufacturing industry is well researched, however there is very little research on the impact of waste on business sustainability [3,4,5]. Not only does the milling industry contributes largely to the South African economy but also globally. Goal 12 of the 17 sustainable development goals to transform the world [5] is focused on responsible consumption and production, and its targets include substantially reducing waste generation through prevention, sustainable management and efficient use of natural resources [11]. Product-rework involves the use of energy and water. Considering water scarcity in South Africa and the fact that wheat-milling organisations, including the organisation under study, do not use renewable energy sources but rely on non-renewable energy sources, the impact of product waste on business sustainability should be investigated. The first part of this study will show the literature that exists on QMPs and the relationships that have been studied. A conceptual framework will then be developed to reflect the relationship between QMPs, product-waste that results in reworks and business sustainability. Quality management as an essential routine activity that is there to prevent defects that have an impact on customers and plays an important role in improving operations and believe that it is the main driver for improvement [12]. QMPs are the crucial and integral activities that organisations practice to oversee and control quality of products. This results in enhanced quality performance and puts the organisation at competitive advantage [13]. QMPs is defined as continuous improvement tools, techniques, and strategies for quality improvement, typically driven by the need to satisfy customers, listing practices such as management Total Quality Monitoring (TQM), statistical techniques of quality, quality assurance, education and training, senior management support, employee involvement, customer orientation and quality systems [14]. The implementation and importance of the full participation of all members of the organisation, including senior management, who help ensure that practices are implemented effectively in various aspects of products, processes and services. Quality management can only be fully implemented with management leadership that can share the quality values with all members of the organisation and that enables employees to carry out the physical and mental activities of the organisation [15].

4.2 Quality management supporting standards and quality management strategies.

4.2.1 ISO9001

One of the systems in place to support the implementation of quality management is ISO 9001:2015, an internationally recognised standard for quality management systems that has two objectives, namely reliability and flexibility. According to [16] , it consists of approaches that enable managers' leadership at all levels of the organisation, reinforced integration of organisational business and other management systems, consideration of all stakeholders and risk-based thinking. Among its benefits are organisational and operational improvements, better brand image, improved customer relationships, better quality and customer satisfaction.

4.2.2 Six Sigma practises

Six sigma as a business strategy and science combining statistical and managerial methods aimed at continuously improving processes by reducing manufacturing costs, which results in better customer satisfaction [17]. Adoption of six sigma practices for quality improvement is focused on reducing variations in the process, resulting in profitability, sales growth and reduced indirect costs [2]. This is achieved through applying sophisticated root cause techniques to be able to control and explore problems [18].

4.2.3 5S Practices

Sustained customer satisfaction and organisational competitiveness could be achieved through lean manufacturing which continually improves processes through cost optimisation, safety, enhanced productivity through waste reduction and full use of resources, thereby improving product quality [19]. One of the building blocks of lean manufacturing is the Japanese philosophy, 5S, which emphasises cleanliness, orderliness and self-discipline. This philosophy advocates the values of trust in the organisation, self-restraint, team-working and organisational commitment. The framework is based on 5 pillars in the Japanese acronym for Seri (organise), Setion (neatness), Sesio (cleaning), Seiketsu (standardisation) and Shitsuke (discipline). The 5 steps of 5S are sort, set, shine, standardise and sustain. When integrated with safety, the philosophy becomes 6S. [19] also state that when 5S is integrated with other quality management initiatives, such as ISO 9001, it helps accrue higher productivity and higher product quality.

4.3 Factors affecting quality management adoption.

Quality management is as an approach or an essential routine activity that is there to prevent defects that have an impact on customers and plays an important role in improving operations [12]. Quality management is also defined as an approach that realises organisational objectives through support from top management, customer relationship, supplier relationship, employee management, product design and process management [2]. Information technology, organisational size, the extent of market competition, product diversity, leadership competencies, organisational culture, manufacturing strategy and organisational structure have been identified and examined in literature as factors that are associated with the adoption of quality management [13].

4.4 Leadership in quality management

Leadership can be defined as “personality characteristics that influence others to pursue the organisation’s goals by attending to their customer’s needs and expectations” [20]. Leadership as one that provides a good work environment for empowerment, innovation and improvement and is always striving to improve performance and communication among project parties [21].

According to [20], not only is leadership fundamental in implementing quality management systems but also in developing an effective organisational environment that involves all employees to pursue quality goals. Leaders have a responsibility to create a connection of trust with employees using effective communication to lead in order to achieve the goals of the organisation while possessing self-confidence and firmly believing in their vision [23]. This is achieved through openness, fairness and honesty to staff and encouraging them to be independent in their decision making [23]. [24] support this by also saying that managers and leaders should possess independence, trustfulness and fairness. This argument is supported by [25] report which promotes ethical and effective leadership and encourages qualities, such as integrity, competence, responsibility, accountability, fairness and transparency.

4.5 Organisational culture

Organisational culture as mutual motives, values, beliefs, identities and interpretations or meanings of significant events that arise from common experiences of members of collectives that are passed down from generation to generation [13]. In a study carried out to investigate the impact of organisational culture on QMPs, a list of reasons for the pattern of failure for successful execution of QMPs as partial deployment and a lack of understanding of organisational culture were presented [26]. The organisational culture of quality begins with a leadership that understands and believes in the implication of systems visions and knows that it is necessary to serve the customer to be successful.

4.6 Relationship between quality management and organisational culture

An existing relationship between organisational culture and the adoption of TQM (one of the quality managements practices) was pointed out by [13]. Teamwork and collaboration, risk taking and open communication, continuous improvement, customer focus, partnership with suppliers, quality monitoring and evaluation. QMPs can contribute to and strengthen the generation of a culture that promotes change and innovation with its teamwork practices that allow employees greater autonomy and power of decision [15]. Organisational culture has been considered as an essential element in the successful implementation of quality improvement programs [27].

4.7 Sustainability

Sustainability is a concept that consists of three perspectives that form the three bottom-line, that is, social, environmental and economic perspectives. There needs to be a balance of the three components, as harmony and integration of these will ensure that sustainability goals are established in an organisation [28]. With a successful implementation of QMPs, business' sustainability is attainable. Tight competition, lack of resources, more informed and demanding consumers, continuous technological innovations, climate change and stakeholders' pressure are challenges that are faced by management to ensure business sustainability. It is essential to integrate sustainability at different management levels, such as strategic and operational levels, considering stakeholders' current and future needs [28]. Sustainable manufacturing is the manufacturing of products with a minimum negative impact on the environment, with conservation of natural resources with economic viability maintaining the safety of employees, community and consumers [2]. Goal 12 of the Sustainable Development Goals [3] is to ensure sustainable consumption and production patterns. This is achieved through making fundamental changes in the way societies produce and consume goods and services [29]. Unsustainable patterns of consumption and production are the root cause of the triple planetary crises, that is, climate change, biodiversity loss and pollution [30]. Rework requires the use of water and electricity. Generally, South Africa is faced with the challenge of water scarcity and power outages. The organisation under study is affected by both these factors and does not use electricity from renewable sources. When there is load-shedding, the mill stands. For the organisation to be able to contribute to Goal 12 of sustainable consumption and production, it means that the mill must use resources responsibly to avoid defects, both those that lead to rework and those that will end up in landfills.

4.8 Integration of sustainability into QMPs

According to [20], "The integration of sustainability into QMS has been defended as a path to the improvement of the organisation's performance and, therefore, can increase its competitive advantage by accomplishing its economic, social and environmental goals". Sustainability goals can be achieved by the implementation of quality management systems, which is a more co-ordinated management process and can meet all stakeholders' needs and expectations [20]. In a study by [31] that aimed to unfold the impact of supply chain QMPs on sustainability performance, the findings were that customer focus has the greatest impact on sustainability performance, with 100% relative importance, followed by quality leadership (75%), information sharing (61.5%) and supplier focus (57.30%).

In a study by [32] that attempted to identify an adequate model that can improve financial performance, the findings were that quality management can improve financial performance. One of the quality management goals is to attain higher profits, and this is achieved through improved QMPs, enhancing process efficiency and cost reduction [28]. This clearly shows a relationship between QMPs and the economic aspect of the triple bottom-line. The results of a quality paper investigating sustainability through QM practices in the food and beverage industry revealed that effective QM implementation has a positive and significant effect on sustainability, and a framework Figure 1 was developed [33]. The conceptual framework was derived from the literature and is represented through the various constructs in Figure 1.

4.6 Conceptual framework

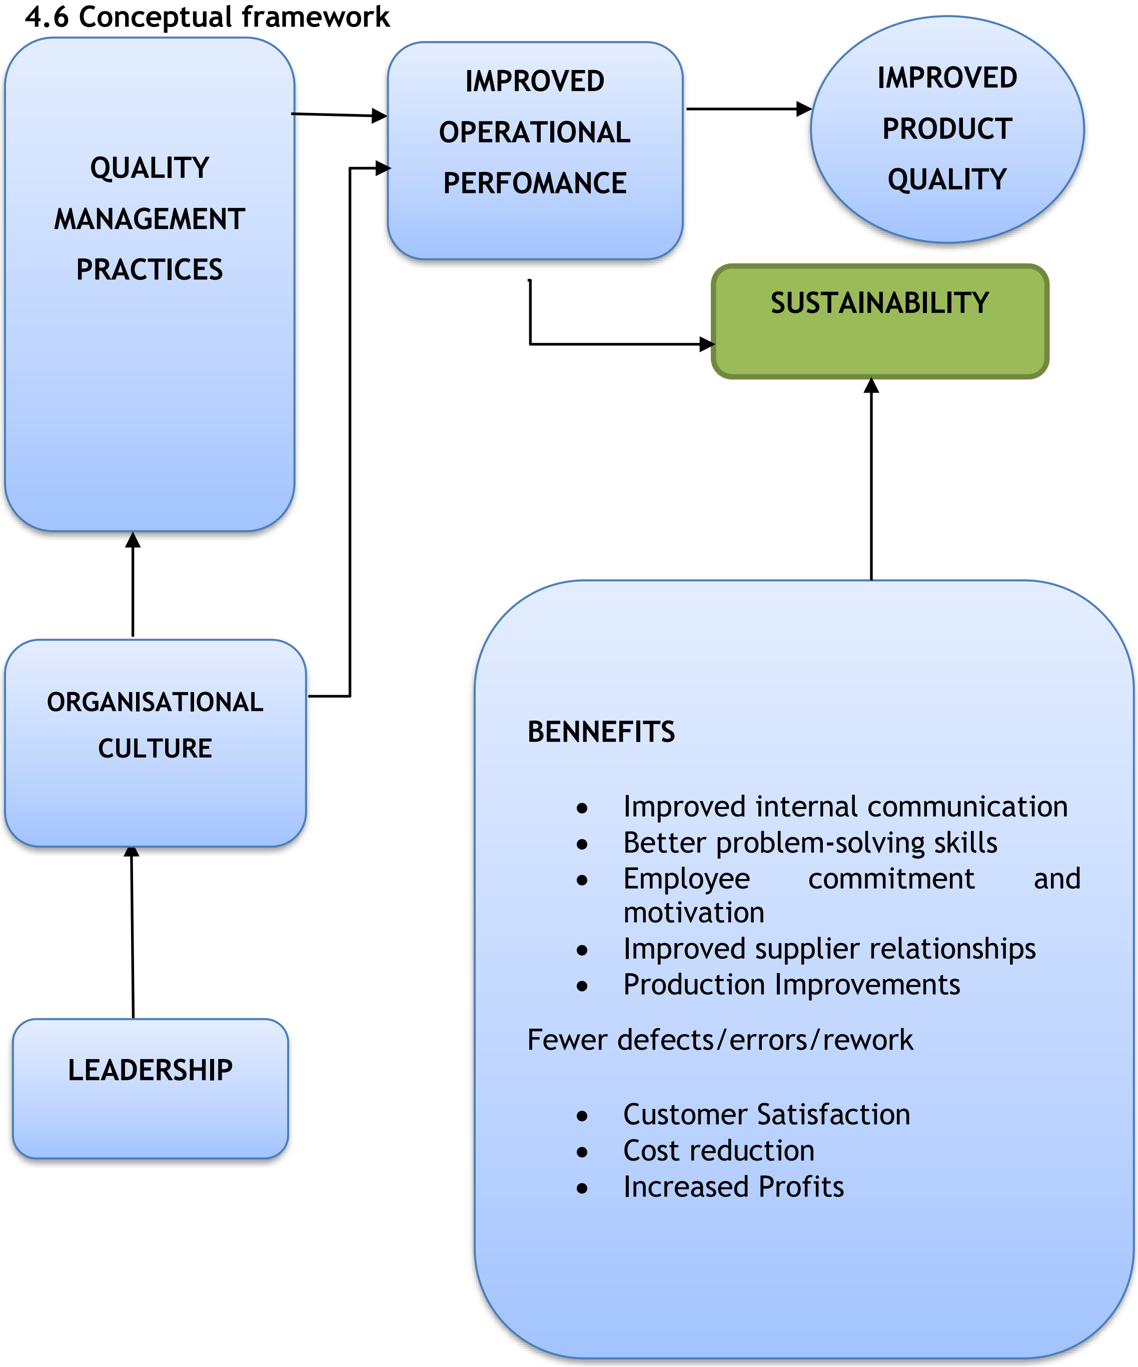

Figure 1: A conceptual framework drawn from literature.

5. RESEARCH METHOD

The research paradigm of this study is explained using the research onion adopted from [39]. The researcher adopted the positivism philosophy, which largely mirrors the philosophical stance of a natural scientist [39]. A deductive approach was taken where the research began on existing theory, hypotheses were developed, and data were collected to confirm or reject a hypothesis. The objective was to test a theory with different groups and contexts to help confirm the theory.

A survey strategy was used to collect data. The timeframe of this study was a cross-section; it involved the collection of data at a specific point in time [39]. Unlike the longitudinal approach, where data are collected repeatedly over a long period, data collection for this study was short-term. This study was based on non-experimental research designs, which are termed as descriptive and correlational.

5.1 Population and sample size

This study adopted census sampling methods, as it is preferrable if the population size is small, as reflected in the sampling frame [40]. In a census sample, all elements of the population are included [41]. A census-based sampling attempts to acquire data from an entire population systematically [42]. This study used primary data, using a census sample method and the chosen sample groups from a population of 219 employees, and included the management, packing, production, quality, SHE (environmental, health and safety), administration and the maintenance departments. A pilot test was conducted on three-management team members. The responses were not added to the sample. The pilot test determined whether the sample population clearly understood the instructions of the questionnaire [46].

Table 2: Population and sample size

Operational Unit	*Total Population*	*Sample size*	*Population %*	*Sample method*
Management	*21*	*21*	*100*	*Census*
Packing	*45*	*45*	*100*	*Census*
Production	*72*	*72*	*100*	*Census*
Quality+ SHE	*15*	*15*	*100*	*Census*
SILO	*15*	*15*	*100*	*Census*
Administration	*15*	*15*	*100*	*Census*
Maintenance	*36*	*36*	*100*	*Census*
Total	***219***	***219***	*100*	*100%*

5.2 Data collection

Primary data were collected through a self-distributed and online questionnaire, which had been chosen because it was efficient and affordable and easily available to every employee who wished to participate.

5.3 Pilot test

The pilot test was conducted on three management team members and thereafter, adjustments were made to the questionnaire before it was distributed to the sample population. The questionnaire covered aspects such as QMPs, organisational culture and leadership and business sustainability. The questionnaire was structured in a manner that the instructions were easy to understand and the language and wording were simple to understand. Also, the questionnaire answered the research questions for the study. The questionnaire used a five-point Likert scale: (1= Strongly disagree, 2=disagree, 3=neutral, 4= agree, 5= strongly agree)

5.4 Vaidity and reliabilty

The scales used in research must be valid and reliable, as these factors will ensure beneficial results.

5.4.1 Validity

Data are termed valid when they are meaningful and can be appropriately interpreted [46]. The instrument's validity was tested using content validity in this study. The content validity was evaluated using statistical methods, specifically factor analysis.

5.4.2 Reliability

Reliability indicates how stable the measured values are when measurements are repeated with the same instrument under the same condition [47]. In this study, reliability was determined by internal consistency. Internal consistency is related reliability of expressions contained in the measuring instrument [46]. Cronbach's coefficient was used to measure internal consistency, and the higher the value or the closer the reliability coefficient to 1.0, the higher the measurement of the items. In this study, Cronbach's alpha values greater than 0.7 represented acceptable reliability, while values greater than 0.8 were considered excellent [46].

6. DATA ANALYSIS AND FINDINGS OF THE STUDY

6.1 Sample analysis

The response rate of this study was 54.8%, meaning that 120 of the initially targeted 219 participants responded. While the sample was significantly lower than the target sample, it was in line with the average response rates of 55.6% for management and leadership studies, as reported by [44].

6.2 Instrument reliability analysis

This section discusses the reliability of the results of the research instruments. The Cronbach's Alpha (α) coefficient was used to measure the reliability of the research instrument. The results are presented in Table 3.

Table 3: Instrument reliability analysis

Instrument	Mean	Variance	SD	α
QMPs	**Six Sigma**			
	16.43	9.00	3.00	0.80
	5Ss			
	16.20	12.12	3.48	0.87
	Quality Management System			
	20.70	18.07	4.25	0.91
	Leadership commitment and support			
	20.84	20.51	4.53	0.94
	Workforce Management			
	25.73	42.71	6.54	0.91
	Organisational Culture			
	7.34	4.42	2.10	0.93

Instrument	Mean	Variance	SD	α
Sustainability	Operational Performance			
	12.23	7.30	2.70	0.84
	Business Financial Sustainability			
	46.45	92.30	9.61	0.92
	Quality Performance			
	25.20	29.24	5.41	0.84
	Business Performance			
	21.25	22.42	4.74	0.89

6.3 Regression analysis

To test the impact of QMPs on organisational sustainability, the regression model was developed. The results of the regression analysis are presented in this section. The discussion is done for each of the research hypotheses as presented in the literature review.

6.3.1 QMPs on organisational performance

The first hypothesis (H_1) was stated as:

H_1 QM practices have a direct impact on organisational performance.

Table 4 presents the results of regression modelling to prove the hypothesis.

Table 4: Impact of QMPs on organisational performance

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.716[a]	.513	.501/t5r01	3.34448	.513	44.205	1	42	.000
a. Predictors: (Constant), QM									

The results in Table 4 show that QMPs accounted for 51.3% of the variations in organisational performance (r square = 0.501, $p < 0.01$). It can be concluded that QMPs have a statistically significant positive impact on organisational performance. Thus, the results confirm and support H_1.

6.3.2 QMP on product quality

The second hypothesis was: H_2 QMPs have an impact on product quality. Regression analysis results to prove the hypothesis are presented in Table 5.

Table 5: Impact of QMPs on product quality

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.844[a]	.712	.705	2.93506	.712	103.934	1	42	.000
a. Predictors: (Constant), QMP									

The results in Table 5 show that 71.2% of variations in quality performance can be explained by variations in QMPs (r square = 0.712, $p < 0.01$). Based on these results, it can be concluded that QMPs have a statistically significant positive impact on product quality. Thus, the results confirm and support H2, which proposes that QMPs have a positive impact on product quality.

6.3.3 Influence of leadership commitment and support on QM practices

The third research hypothesis was stated as:

H_3 Leadership commitment and support have an impact on the implementation of QM practices.

The results to prove the hypothesis are presented in Table 6.

Table 6: Influence of leadership commitment and support on QM practices

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.932[a]	.869	.866	5.97538	.869	278.980	1	42	.000
a. Predictors: (Constant), Lcs									

The results in Table 6 show that 86.9% of variations in QMPs can be explained by variations in leadership commitment and s (r square = 0.869, $p < 0.01$). Based on these results, it can be concluded that leadership commitment and support have a statistically significant positive impact on QMPs. Thus, the results confirm and support H3, which proposes that leadership commitment and support have a positive impact on QMPs.

6.3.4 Organisational culture on QM practices

This section presents results to test the fourth hypothesis: H_4 Organisational culture has an impact on QM practices. The results are presented in Table 7.

Table 7: Organisational culture on QM practices

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.778[a]	.605	.596	10.37602	.605	64.450	1	42	.000
a. Predictors: (Constant), Ogc									

The results in Table 7 show that 60.5% of variations in QMPs can be explained by variations in organisational culture (r square = 0.605, p < 0.01). Based on these results, it can be concluded that organisational culture has a statistically significant positive impact on QMPs. Thus, the results confirm and support H4, which proposes that organisational culture has a positive impact on QMPs.

6.3.5 QMP on business sustainability

Table 8: QMP on business sustainability

Model Summary									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.865[a]	.749	.743	10.72223	.749	125.138	1	42	.000
a. Predictors: (Constant), Qmp									

The final hypothesis of the study was that QMPs have an impact on business sustainability: H5 QMPs have an impact on business sustainability. The results to test that hypothesis are presented in Table 8.

The results in Table 8 show that 74.9% of variations in business sustainability can be explained by variations in QMPs (r square = 0.749, p < 0.01). Based on these results, it can be concluded that QMPs have a statistically significant positive impact on business sustainability. Thus, the results confirm and support H_5 which proposes that QMPs have an impact on business sustainability.

7. KEY RESEARCH FINDINGS

The study adopted a quantitative approach method to study the perceptions of QMPs on the sustainable wheat-flour milling business.

7.1 Descriptive statistical analysis results

7.1.1 QMPs

The results conclude that the organisation under study practises 5S practices [12,14]. According to [19], 5S practices lead to improved quality performance. Quality management system also had high means scores, showing that the quality management system in the organisation is effective. Process management was also perceived to be functioning by the participants.

7.1.2 Sustainability

Organisational sustainability was broken done into two factors namely, quality performance and business performance. The quality performance factor gave high mean scores. Thus, participants, on average, felt that the quality performance has been above average. The mean scores for organisational performance were higher than the 2.50 threshold; they were relatively lower than those of other factors and were all less than 4.00 (3.07-3.82). This implies that there is still room for improvement on the organisation's overall business and sustainability performance.

7.2 Correlational analysis

Sustainability was found to be positively correlated with QMPs. Thus, all the factors of QMPs were found to be positively correlated to sustainability namely, Six Sigma, 5Ss, quality management system, leadership commitment and support, workforce management and organisational culture. It can, therefore, be concluded that QMPs, together with their respective factors, as measured in this study, have a positive effect on business sustainability. The results in this study support those earlier studies, such as [10], [20], and [44] who all found that QMPs influence organisational performance.

7.3 Regression analysis

The results have proved that QMPs have a statistically significant positive impact on organisational performance. Thus, the results confirm and support hypotheses that were identified for this study.

8. RECOMMENDATIONS

Based on the results of this study, the work force management system needs to be improved in the organisation, as the mean scores were lower than those of other factors, and there was high variability in respondents' responses. This could be achieved by using Artificial Intelligence (Al) and machine learning to improve employee experiences and engagements. The Al strategies will also help measure employee productivity and efficiency. The overall business' sustainability performance needs some improvement. Organisational sustainability was broken done into two factors: quality performance and business performance. Participants, on overage, felt that the Miller's quality performance has been above average. On the other hand, the business performance factor had mean scores that were relatively lower than those of other factors and were all less than 4.00. This implies that there is still room for improvement on the Miller's overall business and sustainability performance. There is a weak link in the value chain that affects quality performance, and the management needs to draw up strategies to get to its root.

9. CONCLUSION

This study investigated The Impact of QMPs on Sustainable Wheat-Flour Milling. The aim was to expose the factors that affect QMPs in the wheat-flour milling organisation, the most significant QMPs that influence rework in the wheat-flour milling organisation and lastly, provide recommendations on how to improve QMPs in wheat-flour milling organisations. The study initially targeted 219 participants and the response rate was 54.8%, which was lower than expected. This could have been due to the limited time the researcher had to collect data. A similar study at the company could be conducted in the future and the researchers should give themselves enough time to collect data to ensure a high rate of responses. The study focused exclusively on wheat-flour mills in one organisation. The results may not be reflective of other milling organisations. While the sample size was adequate, valid, future studies could be extended and expanded to other wheat-milling organisations facing a similar challenge as the company under study to draw more definitive statistical conclusions on the target population. All the objectives of the study were achieved. QMPs, such as six sigma practices, 5S practices, quality management system implementation and process management, were found to be affected by factors, such as organisational culture, workforce management and leadership support and commitment in the wheat-flour milling organisation. Workforce management was found to be the most significant factor that affects the implementation of QMPs. All QMPs factors studied do have an impact on product quality. Poor implementation of these practices results in poor product quality, leading to high volumes of rework. Workforce management needs some improvement, as it could be affecting quality performance. On average, participants felt that quality performance was just above average in the last three years thereby leading to low mean scores for business performance compared to other factors. It was, therefore, proposed by the researcher that for future studies, a more in-depth feedback approach from the respondents be used through a qualitative or a mixed methods approach.

SURVEY QUESTIONAIRE

THE IMPACT OF QUALITY MANAGEMENT PRACTICES ON SUSTAINABLE WHEAT-FLOUR MILLING

Please take time to read the following information. If at any point you have questions please do contact the researcher, Andisiwe Nwabisa Mdoda at 65102959@mylife.unisa.ac.za

Overview

You are herewith invited to participate in an academic research study conducted by Andisiwe Mdoda, a student in the Master of Business Administration at UNISA's Graduate School of Business Leadership (SBL).

The purpose of the study is to explore the impact of Quality Management Practices on sustainability of Wheat-Flour milling business as the Wheat-Milling industry is a major contributor to the global economy and thus Quality Management Practices are of high importance in the wheat-milling industry. This study will expose the factors that affect Quality Management Practices, the most significant Quality Management practice that influences rework and lastly provide recommendations on how to improve Quality Management Practices in wheat milling organisations.

All your answers will be treated as confidential, and you will not be identified in any of the research reports emanating from this research. Your participation in this study is very important to us. You may however choose not to participate and you may also withdraw from the study at any time without any negative consequences.

The questions consist of 3 sections, namely; Informed Consent, Demographic Information and the last section is made up of questions pertaining to the research problem. You will not be expected to make any financial contributions as a participant in this study. There will be no financial benefits, gifts or compensation in exchange for completing this questionnaire.

Please answer the questions in the attached questionnaire as completely and honestly as possible and please return the questionnaire to the researcher not later than 25 November 2022. This should not take more than 30 minutes of your time. The results of the study will be used for academic purposes only and may be published in an academic journal. We will provide you with a summary of our findings on request.

Please contact my supervisor, Prof Sugandren Naidoo by email at naidoosu@unisa.ac.za if you have any questions or comments regarding the study. Please continue to the next section to start with the survey.

1. INFORMED CONSENT

By continuing with the sections below, you as the participant acknowledge that you have read and signed the participants informed consent form and that you are willing to participate.

After section 1 Continue to next section

Section 3 of 9

3. QUALITY MANAGEMENT PRACTICES

This section contains questions about Quality Management Practices in your organisation. State your level of agreement or disagreement with the given statements by selecting the responses which best describe your organisation.

Please select your answer on the scale from (1 = Strongly disagree 2=Disagree 3=Neutral 4= agree 5= strongly agree)

Six Sigma

Description (optional)

3.1 Green belt/black belt are able to measure processes (defects per million opportunities, sigma level, process capability indices, defects per unit and yield) to evaluate process improvements.

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

3.2 Green/black belts are encouraged to take up case studies to be solved through 6S

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

3.3 The organisation pursues a formal planning to improve the business processes.

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

3.4 The organisation measures performance of processes against customers' requirements

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

After section 3 Continue to next section

Section 4 of 9

4. 5S PRACTICES

Description (optional)

4.1 All 5S steps are deployed

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

4.2 There is improved housekeeping in the workplace of the organisation

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

4.3 Visual indicators are deployed to identify proper location

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

4.4 Place for everything, everything in its place is practiced

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

After section 4 Continue to next section

Section 5 of 9

5. QUALITY MANAGEMENT SYSTEM

5.1 The PDCA (Plan-Do-Check-Act) cycle in my organisation is used as a standard operating procedure for continuous quality improvement efforts.

1	2	3	4	5
○	○	○	○	○

5.2 Quality objectives are clearly and specifically defined in the organisation

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

5.3 Product's specification provided by the customers are verified and validated

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

5.4 Clear work instruction exists for all business processes

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

5.5 Internal/external audits are effective in terms of reduction of non-conformity

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

After section 5 Continue to next section

Section 6 of 9

6. OPERATIONAL PERFOMANCE

Description (optional)

6.1 In your organisation, production is stopped immediately for quality problems

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly Agree

6.2 Your organisation conducts preventive equipment maintenance

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly Agree

6.3 In your organisation, shop floors are well organised and clean

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly Agree

After section 6 Continue to next section

Section 7 of 9

7. LEADERSHIP COMMITMENT & SUPPORT

Description (optional)

7.1 Your organisation's top management is evaluated for quality performance

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

7.2 In your organisation, major department heads participate in the quality improvement process

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

7.3 In your organisation, "Quality issues" are reviewed in top management meetings

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

7.4 In your organisation, top management views quality performance as a major objective

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

7.5 In your organisation, quality policy is developed by top management

	1	2	3	4	5	
Strongly disagree	○	○	○	○	○	Strongly agree

After section 7 Continue to next section

Section 8 of 9

8. ORGANISATIONAL CULTURE AND WORKFORCE MANAGEMENT

8.1 WORK FORCE MANAGEMENT

8.1.1 Your organisation provides feedback to employees on their quality performance

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.1.2 Contractual employees are also involved in quality decisions in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.1.3 Quality-related training is given to contractual employees

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.1.4 Quality-related training is given to managers and supervisors in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.1.5 Your organisation provides quality Training as "total quality concept" (i.e., philosophy of company-wide responsibility for quality)

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.2 ORGANIZATIONAL CULTURE

Description (optional)

8.2.1 In your organisation group culture is encouraged in terms of participation, open discussion, empowerment of employees to act, assessing employee concerns and ideas, human relations, teamwork, and cohesion

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

8.2.2 In your organisation development culture is driven in terms of flexibility, decentralization, expansion, growth, and development, innovation and change and creative problem-solving processes

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

After section 8 Continue to next section

Section 9 of 9

9. BUSINESS FINANCIAL SUSTAINABILITY

9.1 QUALITY PERFOMANCE

9.1.1 Quality of your organisation products and services has been improved over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.2 Process variability in your organisation has decreased over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.3 Delivery of your products and services has been improved over the past 3 years in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.4 Cost of scrap and rework as a percentage (%) of sales has decreased over the past 3 years in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.5 Over the past 3 years, cycle time (from receipt of raw materials to shipment of finished products) has decreased in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.6 Customer satisfaction with the quality of products and services has increased over the past 3 years in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.1.7 Equipment downtime in your organisation has decreased over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2 BUSINESS PERFOMANCE

Description (optional)

9.2.1 Your organisation sales have grown over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2.2 Your organisation's market share has grown over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2.3 Unit cost of manufacturing has decreased over the past 3 years in your organisation

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2.4 Your organisation's operating income has grown over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2.5 Your organisation's profits have grown over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

9.2.6 Return on assets of your organisation has increased over the past 3 years

	1	2	3	4	5	
Strongly Disagree	○	○	○	○	○	Strongly Agree

Thank you for taking part in this survey.

ABSTRACT

The survival of all organisations that operate in a global economy depends on delivering quality products and services with a focus on exceeding customer expectations. A quantitative research approach was employed in this study. An online survey questionnaire was deployed to gather data from a sample of at least 100 employees of business support employees of a financial service organisation in South Africa. Analysis of the data was done using descriptive statistics and inferential statistics. Results of the study revealed that TQM positively influences organisational performance. This implies that if there is any improvement or deterioration in any of these factors it will have an influence on organisational performance. Further, the results of the have managerial implications when it comes to strategies for improving the quality-of-service delivery of the financial service organisation.

Keywords: Total quality management, organisational performance, customer satisfaction, customer focus, continuous improvement

1. INTRODUCTION

Organisations all over the world have been actively working over the past several decades to cope with the quickly changing business landscape in which management must attempt to develop a long-term solution to maintain or acquire a competitive edge [1]. To meet new global problems, most organisations have implemented new philosophies such as Lean Production, Just-In-Time [JIT] methods, Total Quality Management [TQM], Business Process Re-engineering [BPR], amongst others [2]. The primary motivation for these ideologies is to improve the organisation's performance both internally and externally within its market goals.

Total Quality Management [TQM] is a management tool, philosophy, and set of principles that can be implemented across all operations and functions of an organisation to continuously improve the quality of products and services [3], exceed customer satisfaction, and continuously reduce production costs. The TQM technique is not just limited to quality enhancements in manufacturing.

Singh, et al., [1] notes that the absence of one feature in one banking institution may cause clients to choose a competing bank. As a necessity to the success of the banking system, it is important for a bank to deliver the best service quality [4]. The Financial Services sector is a highly competitive market and thus this study focuses on the impact of TQM on organisational performance in the context of the banking sector, within South Africa. This research study will focus on the context of the research challenge, the justification of the study, research objectives, discussion of key concepts of the study as well as a framework of the research methodology.

1.1 The research problem

According to a series of complaints in day-to-day interactions with bank clients, comments on social media platforms, and opinions on print media, despite the attention paid by banks to TQM, clients are nevertheless unsatisfied in most situations. Given the highly competitive nature of the financial sector, as well as high operating expenses, high research, and development (R&D) expenditures, and high client expectations, many organizations are always looking for methods to increase quality while remaining cost efficient (Nazar et al. 2018). Because of the ever-changing technological environment, all economic units are being forced to undertake digital transformation as part of comprehensive quality management (Khwela, N.C., 2019). The banking sector has increased its IT investments to continually modify its business model to improve how the bank interacts with its clients, manage internal processes, and remain competitive and be future ready. The challenge is whether clients are willing to adapt to new ways of doing business and whether general staff can provide the required customer satisfaction and service quality that has been promised. The reality is that banks clients often complain about service concerns such as delayed ATM cards, card retraction, illegal withdrawals, long queues in banking halls, and the bad service of bank personnel in attending to customers and addressing such complaints, among other things. Below are the stats for the complaints reported to the Ombudsman for Banking Services (OBS) South Africa. In terms of Section 8 of the conduct of standards for banks, banks must establish, maintain, and operate an effective an adequate complaints management framework to ensure the fair treatment of consumers. Table 1 shows some of the categories of complaints captured by OBS.

Table 1: Banking Complaints opened by Ombudsman for Banking Services by year.

	2020	2021	2022
Current Account	12%	19%	16%
Internet Banking	18%	13%	19%
Credit Cards	15%	11%	9%
Mortgage Finance	8%	8%	8%
Personal Loans	11%	11%	11%
ATM	13%	9%	7%

Source: OBS (2021)

Table 2: Cased opened by OBS South Africa by banks Category.

	2019	2020	2021
Standard Bank	1 127	1 572	2 070
Capitec Bank	763	1 259	1 651
FNB	1 707	2 197	1 452
Nedbank	1 094	1 220	1 273
ABSA	1 483	943	1 068
African Bank	151	255	285

Source: (OBS)

Internet banking complaints increased by 6% year on year, 45% of these complaints were brough against the Capitec and 20% against Standard Bank. Mobile banking made up 25% of this category. Current accounts complaints were the 2nd highest category of complaints opened by the OBS. Table 2 reveals ATM complaints decreased in 2020 and 2021 as most people were isolating due to the COVID-19 pandemic (OBS).

Table 3: Banking Complaints opened by Ombudsman for Banking Services by year Banking Complaints opened by Ombudsman for Banking Services by category

	Complaints about advice to financial customer	Complaints about service, support and staff conduct	Complaints about design of financial products and fees	Complaints about disclosures to and information provided	Complaints about performance of financial products and services	Complaints about customer services

Internet Banking			75	79	1216	
Business Finance				38	21	1
Car Finance		80	165	136	207	20
Credit Cards	1	25	334	257	204	36
Credit Information Disputes			14	10	282	

	Complaints about advice to financial customer	Complaints about service, support and staff conduct	Complaints about design of financial products and fees	Complaints about disclosures to and information provided	Complaints about performance of financial products and services	Complaints about customer services
Covid -19				78	27	
Savings Account			19	146	304	9
Current Account			149	555	496	
Investments	5	20	5	34	89	1

Source [OBS]

Table 3 indicates the problems experienced by banks and is huge concern should banks want to remain competitive. Moreover, the South African Consumer Satisfaction Index, which is operated by the consultation group Consulta, surveyed almost 15 000 customers from across the 6 major retail banks in South Africa. The results of the survey showed that the South African banking standards are rated like world class for customer satisfaction, and thus expectations are extremely high and likely to keep rising. Therefore, banks need to understand the nature of these expectations which includes striking a balance between digital convenience, value delivery and human intuition and client engagement.

1.2 Aim of the study

The aim of this study is to assist financial services industry understand the impact of Total Quality Management (TQM) on organisational performance.

1.3 Research questions

The following research questions were defined for the study:

- What are the TQM factors that influence organisational performance at the South African banking organisation?
- What is the impact of the TQM factors on organisational performance at the banking organisation?
- What recommendations can be made to the banking management, as input to their organisational strategy on how TQM can be practiced to improving organisational performance?

2. OVERVIEW OF TOTAL QUALITY MANAGEMENT

Quality is a criterion that determines whether a product or service is superior or inferior. Quality is a feature that distinguishes a product or service from its rivals [5].

In the 1960s Feigenbaum conceptualised Total Quality Control. He believed that all departments in a company have some responsibility for the achievement of quality. The challenge with TQC concept was that it did not embrace other management principles such as teamwork, supplier development relationship and people development and leadership [6, 7]. Converting organisational goals into results is accomplished through three managerial processes called the Juran Trilogy [Quality Planning, Quality Control, and Quality Improvement] [8]. According to Ross [9], TQM is more than simply a management tool; when implemented well it may provide significant competitive advantage. The TQM strategy incorporates in an organised manner the core techniques and ideas of quality function deployment, statistical control, and current management tools.

TQM focuses on organisational frequent process improvement to produce greater client value and attain their requirements [10,11]. TQM, as a common organisational management guideline, is used to produce organisation information that is important for creating strategic information maps [12].

3. LITERATURE REVIEW OF TOTAL QUALITY MANAGEMENT PRINCIPLES

There are various approaches for businesses to take to achieve this, with the road to successful continuous improvement based on the use of strategy, data, and effective communication to embed a quality discipline into the organisation’s culture and procedures [13]. Bajaj, Garg and Sethi [14] point out that to successfully implement TQM procedures, the entire organisation must work as a unified unit in a quest for excellence.

TQM focuses on the processes that businesses use to generate their goods, and it requires organisations to identify those processes, continually evaluate and assess their performance, and utilise that performance data to drive changes [1]. Moreover, it encourages all workers and organisational divisions to participate in this process.

TQM procedures are also dependent on a common set of values and beliefs across all organisational members [11]. Quality has evolved from being viewed as a non-price component on which imperfect competition in markets is based to being viewed as a strategic resource of enterprises. In other words, quality is no longer one-dimensional property of a product but a multidimensional construct that must be controlled and whose application leads to a dynamic capability of enterprises [12].

TQM may have a significant and positive impact on personnel and organisational development [11]. Companies may build and preserve cultural norms that ensure long-term success for both clients and the firm by having all workers focus on quality management and continual improvement [6]. TQM's emphasis on quality aids in the identification of skills gaps in personnel, as well as the required training, education, or mentorship to remedy such weaknesses.

3.1 TQM in context of the study

The higher the degree of satisfaction and original anticipation attained by clients, the higher the service quality obtained [15]. The scientific foundation of quality management is built on the genesis of quality objectives, which are based on the demands of the customer [9]. According to Nazar et al. [16], the term service quality means that the organisation should assure customer satisfaction as well as the lack of faults or delays. An effective quality management system must fulfil and exceed the expectations of the customer. [17] identifies critical TQM factors which are, customer focus; continuous improvement; teamwork and participation; top management commitment; training and development; quality systems and policies; supervisory leadership; supplier management; people and culture change. According to Al-Qahtani, et al., [18] organisations have realised that to remain internationally competitive, they must conduct self-evaluations to continually improve organisational performance.

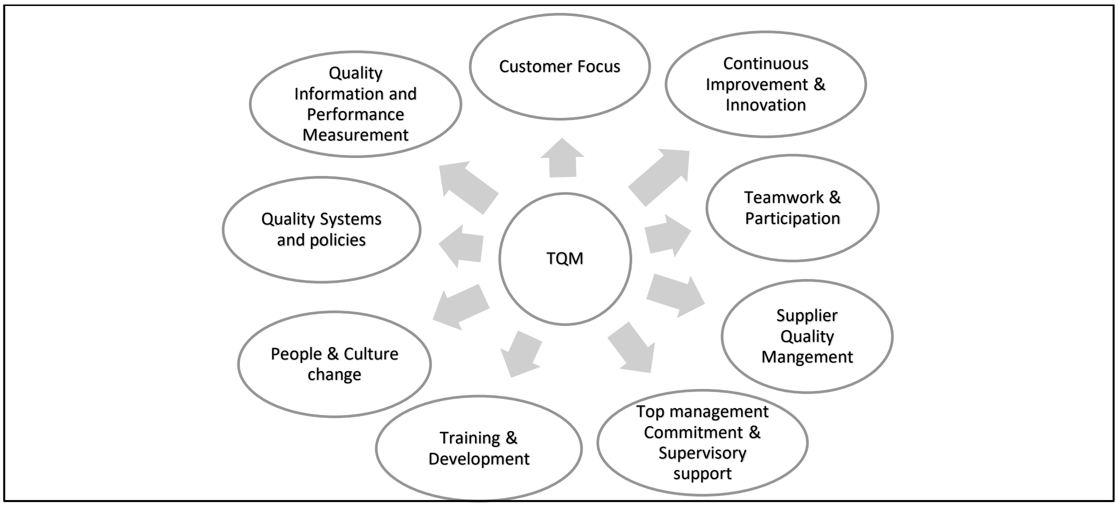

Figure 1: TQM Critical Success Factors *[17]*

Implementing a TQM system must be part of pleasing customers and exceeding their expectations. Such a system must be dynamic, adaptive to the needs, requests, and expectations of the clients. Singh, et al., [1] claim that all organisations want to expand their operations; but, to reach these goals, products and services must be carefully designed and of high quality. The TQM strategy is crucial for ensuring that the goods or service meets or exceeds the customer's expectations. The critical factors required to measure organisational performance are listed on Figure 2 shows which are productivity, Lower lead times, less rework, customer loyalty and relations, improved market share customer satisfaction, lower costs, long term relations and affinity [19, 20].

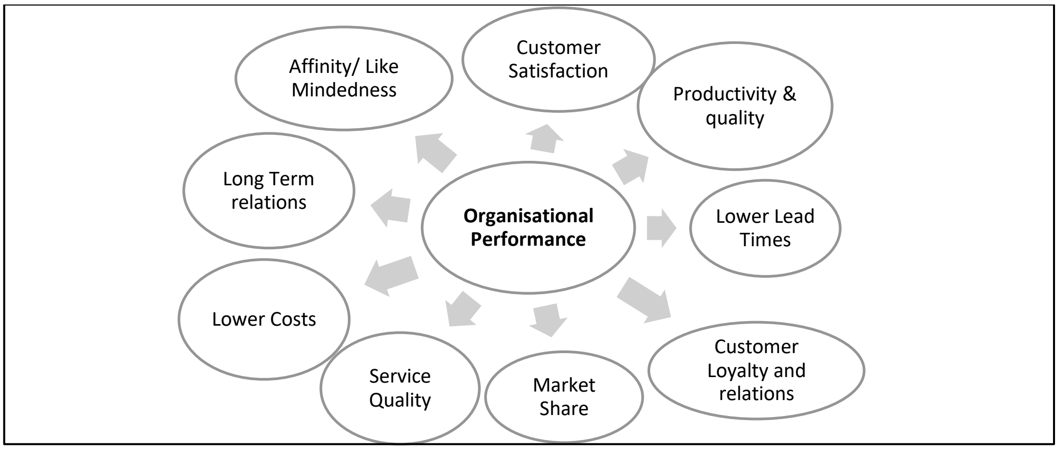

Figure 1: Organisational performance factors [20]

Total Quality Management is thus a technique that seeks to confirm that the final service or product offered to the consumer meets the required standards. The effective implementation of TQM could then lead to the fundamental solutions required for organisations to have competitive advantage in the ever-changing global market conditions.

3.2 Total Quality Management Key Factors

3.2.1 Customer focus

Customer focus becomes an important aspect for an organisation's success since it is the beginning point for every quality project [10]. It is encouraged to conduct research in the case of service sector and to clarify the long-term influence of customer focus on other organisational performance.

3.2.2 Continuous improvement

Continuous improvement focuses on collection of processes that enable an organisation to improve efficiencies and effectiveness. It drives the organisation to be both analytical and creative in finding ways to become more competitive and effective at meeting stakeholders and client expectations. The organization determines and selects opportunities for improvement and implements necessary actions to achieve the intended outcomes. Considering the results from analysis, evaluation and management review, the organization continually improves suitability, adequacy and effectiveness [11].

3.2.3 Strategically based TQM

The strategic strategy of a complete quality firm is meant to offer it a lasting competitive edge in the marketplace, writes Goetsch and Davis [21]. The key motivator for TQM application in organisations is the competitive edge that it provides to the organisations as they provide world class quality products and services. It also includers various aspects such as mission, broad aims, and actions carried out with the aim of achieving the objectives of the business in which senior management is responsible for quality leadership [17]. The TQM strategy considers customer satisfaction, cost of quality and partnerships [21].

3.2.3.1 Customer Satisfaction

According to Lau et al. [11], customer satisfaction, staff participation, executive leadership, and process improvement and control are four components usually recognised as vital to a successful TQM approach.

3.2.3.2 Cost of Quality

Özmen et al. [15] believe that the cost of quality to be the fundamental method for gauging quality. It is utilised in their strategy to track the efficacy of the TQM process, choose quality improvement projects, and justify costs to sceptics.

3.2.3.3 Partnership

Long-term, cooperative partnerships with some of the suppliers will help to achieve excellent resources and/or services encourage supplier quality management that is effective [12]. By endorsing improved supplier commitment to product design and quality, keeping a small number of suppliers promotes product quality and buyer productivity.

3.3 Total employee participation

Through opportunities to obtain and exercise new skills, total employee participation and collaboration may inspire employee motivation and success. The improvement of the employee information, skills, and determination will result in the organisational growth [7]. Employee involvement and empowerment, as well as the utilisation of self-managed teams, are employed as indicators of complete employee involvement in this study.

3.4 Organisational Performance

Considerable effort has been devoted in organisational research to examine the organisational performance factors [13]. This is due to the subject's relevance in reflecting the course of growth for any company, as well as the consequences of these studies on organisational performance and competitiveness [9].

3.5 Conceptual framework

The conceptual framework in figure 3 depicts the factors investigated for this study.

Figure 3: Conceptual framework

From the literature review, it was evident that customer focus, continuous improvement, TQM strategic planning, and total employee participation are the essential characteristics of TQM [16].

4. RESEARCH METHODOLOGY

This chapter discusses the key methodological process that will be followed in this study. the thrust is to assess the impact of total quality management on organisational performance at the banking institution.

4.1 Research design

The research design articulates the exact logical steps that researchers choose to take when solving a research question [22]. This means that the study design is used to determine the type of data needed to conduct the study, the methods for starting the sample, collecting the data, and its subsequent analysis

4.1.1 Descriptive Research Design

The study used a descriptive research design, in which researchers attempted to observe subjects without intervention. The study used a survey approach to solicit valuable information for the research,

4.1.2 Quantitative research approach

This study used quantitative research methods. The goal of quantitative research is to better understand the social environment [22]. This study used a causal research design to establish causal relationships between quantitative variables.

4.1.3 Research Strategy

Research strategies are thought to be influenced by the nature of the hypothetical relationship that exists between research and theory [23]. The study used a questionnaire with standardised questions to allow easy comparison of responses.

4.1.4 Population and sample framework

A population is the total group about whom one wishes to draw conclusions [23]. The target population for this study is business support employees of financial service organisations in South Africa. The identified organisation assisted in providing access to data collection across all South Africa.

4.1.5 Sampling strategy

The study employed probability sampling as it mitigates and avoids bias by using statistics rather than judgement or bias [22]. The same strategy allows researchers to estimate the reliability of the data by testing the validity and reliability of the data.[23] further demonstrated that probabilistic sampling makes the study of the entire population feasible by allowing the study to study a portion and generalise the results.

4.1.6 Sample Size

A sample is the exact group from whom statistics are collected. According to Kumar's (2018) suggestion, a sample size of at least 100 observations is sufficient for quantitative studies. The research will select a sample of 100 employees in the financial services organisation. Convenience sampling was used, whereby respondents who were easily available were selected.

4.1.7 Data collection method

This study involved the use of primary data. The questionnaire was uploaded to Quest Survey, and the link was shared via online platforms like WhatsApp and emails.

4.1.8 Rationale for Using Survey Questionnaires

In general, it is relatively quick to collect large amounts of data using questionnaires. The questionnaire was structured on a 5-point Likert scale, in which responses were listed from a list of agree, strongly agree, neutral, disagree, and strongly disagree. The questionnaire was sent by mail [22].

4.1.9 Pilot Study

Pilot studies are also known as feasibility studies, in which research tools are tested on a small group of participants who will not be included in the actual study.

4.1.10 Validity

The notion of validity characterises the degree to which the test indicates the universe of substances from which it is generated [25] . This infers a degree to which the assessment determines the proposed outcomes.

4.1.11 Reliability

The concept of reliability assesses whether a research instrument will produce similar results if stressed in similar conditions [23]. The reliability of the scales will be assessed using Cronbach's alpha. For a scale to be considered reliable, the alpha coefficient should be greater than 0.7 [25].

5. DATA ANALYSIS

The quantitative data collected with the online research questionnaire were analysed with descriptive and inferential statistics.

Convenience sampling was used to select 150 employees, and an email invitation was sent to them to participate in the online survey. A total of 99 usable data sets were received, giving a participation rate of 66%.

5.1 Department Profile of Respondents

Respondent's department profile and department composition statistics are presented in Figure 4.

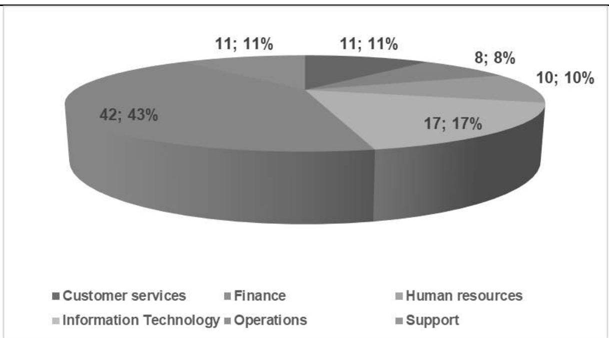

Figure 4: Department Profile of Respondents (n = 99)

Figure 4 shows that the bulk of the respondents—43%—work in operations, with 17% in IT. Customer Services and Support each at 11%, and the remaining 8% at Finance and 10% at Human Resources. It is accepted that most of the respondents are operational.

5.2 Descriptive Statistical Analysis of Quantitative Data

In this section, the descriptive statistics of the qualitative data collected with the research questionnaire are presented. The respondents were presented with an online questionnaire and asked to indicate how much they agreed with a set of statements.

5.2.1 Organisational Performance Scale

The descriptive statistics of the organisational performance questions are presented in Table 4.

Table 4: Descriptive statistics of Organisational Performance Scale (*n* = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
9.6: There is need to improve on the quality of services rendered by the bank to the customer.	4	0.74	0	3	25	53	18	99
			0%	3%	25%	54%	18%	100%
9.7: There is an increase in production percentage.	4	0.82	0	8	17	55	19	99
			0%	8%	17%	56%	19%	100%
9.8: There is an increase in sales compared to the previous periods.	4	0.74	0	4	19	57	19	99
			0%	4%	19%	58%	19%	100%
9.9: There is an increase in profits compared to the previous periods.	4	0.84	0	6	23	46	24	99
			0%	6%	23%	46%	24%	100%
9.10: The bank provides a measurable indicator for operations performance.	4	0.75	0	4	20	55	20	99
			0%	4%	20%	56%	20%	100%

The majority of the respondents agree there is a need for the quality of the services rendered by the bank to customers to be improved (M = 4, SD = .74).

5.2.2 Organisational Strategy Scale

The descriptive statistics of the organisational strategy questions are presented in Table 5.

Table 5: Descriptive statistics of Organisational Strategy Scale (n = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
8.1: The bank applies and support the culture of collective leadership to manage the bank operations.	4	0.82	0	12	37	41	9	99
			0%	12%	37%	41%	9%	100%
8.2: The bank encourages employees to participate in quality improvement initiatives.	4	0.77	0	10	39	43	7	99
			0%	10%	39%	43%	7%	100%
8.3: The bank management has transparent policies to manage employee experience.	4	0.82	0	9	38	40	12	99
			0%	9%	38%	40%	12%	100%
8.15: The bank circulates the strategy to all employees.	4	0.91	1	14	27	46	11	99
			1%	14%	27%	46%	11%	100%
9.16: The bank follows appropriate actions that aimed to increase customer satisfaction.	4	0.80	0	3	36	40	20	99
			0%	3%	36%	40%	20%	100%
9.18: The bank manages customer relationships according to a clear and structured approach.	4	0.77	0	5	33	47	14	99
			0%	5%	33%	47%	14%	100%

Most of the respondents agree that the bank encourages employees to participate in improvements and that the bank manages customer relationships according to a clear and structured approach (*M* = 4, *SD* = .77).

5.2.3 Leadership Scale

The descriptive statistics of the leadership questions are presented in Table 6.

Table 6: Descriptive statistics of Leadership Scale (*n* = 99)

Leadership	*Median*	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
8.4: Bank management has the flexibility and ability to make the right decisions based on the available information, experience, and knowledge.	4	0.80	0	9	37	43	10	99
			0%	9%	37%	43%	10%	100%
8.12: The senior bank management has a long-term plan for the service quality.	4	0.81	0	7	41	38	13	99
			0%	7%	41%	38%	13%	100%
8.13: The bank management revises the statistics used to measure the performance quality to make sure it's valid for the future operations.	3	0.76	0	8	42	41	8	99
			0%	8%	42%	41%	8%	100%
8.14: The banks strategy based is on the understanding of the internal performance of the bank and the available possibilities.	3	0.79	0	10	43	38	8	99
			0%	10%	43%	38%	8%	100%
8.20: Employees are actively involved in planning in our organisation.	3	0.91	1	16	40	32	10	99
			1%	16%	40%	32%	10%	100%
8.21: Reporting work problems is encouraged in our bank.	3	0.86	2	12	41	37	7	99
			2%	12%	41%	37%	7%	100%
8.22: Job satisfaction surveys are conducted regularly to measure employee's satisfaction in our bank.	4	0.91	1	11	35	38	14	99
			1%	11%	35%	38%	14%	100%
8.23: The bank relies on suitable policies to ensure equality and equal opportunities in recruitment, promotion process and employee's rewards.	4	0.88	0	11	38	35	15	99
			0%	11%	38%	35%	15%	100%
8.24: The bank determines the skills and competencies of employees and the required performance level to achieve the vision, objectives and strategy.	4	0.82	0	8	38	40	13	99
			0%	8%	38%	40%	13%	100%
	4	0.89	0	13	29	43	14	99

Leadership	*Median*	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
8.25: The bank evaluates the performance of employees regularly.			0%	13%	29%	43%	14%	100%

The mode values in the above Table 6 show neutral, thus neither agree nor disagree with the statements that the bank management revises the statistics used to measure the performance quality to make sure it is valid for the future operations (*M* = 3, *SD* = .76); the banks strategy based is on the understanding of the internal performance of the bank and the available possibilities (*M* = 3, *SD* = .79); and reporting work problems is encouraged in the bank (*M* = 3, *SD* = .86).

5.2.4 Employee Involvement Scale

The descriptive statistics of the employee involvement questions are presented in Table 7.

Table 7: Descriptive statistics of Employee Involvement Scale (*n* = 99)

Employee Involvement	*Median*	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
8.5: Bank management encourage all employees to submit ideas and suggestions to innovate.	3	0.83	0	12	43	34	10	99
			0%	12%	43%	34%	10%	100%
8.6: Bank management recognises quality improvement suggestions from employees extensively and implement them after evaluation.	3	0.80	0	9	43	37	10	99
			0%	9%	43%	37%	10%	100%
8.7: Bank management seeks to engage all employees in the bank and get their support and contributions.	3	0.88	1	13	37	38	10	99
			1%	13%	37%	38%	10%	100%
8.16: The bank regularly reviews the current strategy in order to improve it.	4	0.88	0	17	26	47	9	99
			0%	17%	26%	47%	9%	100%
8.17: The bank allows employees to participate in its decision making.	4	0.84	1	12	34	45	7	99
			1%	12%	34%	45%	7%	100%
8.18: Bank employees are actively involved in quality-related activities.	3	0.82	0	12	41	37	9	99
			0%	12%	41%	37%	9%	100%
8.19: The bank recognises quality improvement suggestions from employees and extensively implement them after evaluation.	3	0.83	0	13	40	37	9	99
			0%	13%	40%	37%	9%	100%

The respondents indicated that the bank recognise and implement valuable suggestions and input from employees (*M* = 4, *SD* = .81).

5.2.5 Total Quality Management Scale

The descriptive statistics of the Quality Management questions are presented in Table 8.

Table 8: Descriptive statistics of Quality Management Scale (*n* = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
8.8: The bank management has general strategic goals for quality dependent on the wants and needs of customers.	4	0.95	1	14	33	36	15	99
			1%	14%	33%	36%	15%	100%
8.9: The bank management uses data of the other competitors to improve the service.	3	0.91	1	13	38	35	12	99
			1%	13%	38%	35%	12%	100%
8.10: The bank has a system to study the market and the economic changes.	4	0.85	1	11	35	43	9	99
			1%	11%	35%	43%	9%	100%
8.11: The bank management has methods to follow up changes in customer needs.	4	0.83	0	9	36	41	13	99
			0%	9%	36%	41%	13%	100%
9.19: The bank management and its employees are making preventive and immediate corrective actions for the errors reported.	4	0.85	1	7	30	47	14	99
			1%	7%	30%	47%	14%	100%

Table 8 depicts the agreement of the respondents that the bank has methods to follow up on changes in customer needs (M = 4, SD = .83) and that bank management and its employees are taking preventive and immediate corrective actions for the errors reported (M = 4, SD = .85).

5.2.6 People Management Scale

People management is the act of hiring, leading, and developing team members to fulfil the overall purpose of the business (Burns, 2012). People managers are in charge of all people-related functions such as discovering new talent, engaging employees, and advancing their careers (Burns, 2012). They are often in charge of new employee onboarding and training. The descriptive statistics of the People Management questions are presented in Table 9.

Table 9: Descriptive statistics of People Management Scale (*n* = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
9.1: The bank provides the necessary training to improve employee's performance.	4	0.76	0	4	24	53	18	99
			0%	4%	24%	54%	18%	100%
9.2: Bank employees are satisfied with the working conditions.	4	0.75	0	2	39	42	16	99
			0%	2%	39%	42%	16%	100%

9.3: The bank has greatly improved in the overall quality of services rendered to their customer.	4	0.75	0	3	34	47	15	99
			0%	3%	34%	47%	15%	100%
9.4: Every member of the bank staff is committed to maintaining high standard of work in every aspect of the banks' operation.	4	0.87	0	10	24	48	17	99
			0%	10%	24%	48%	17%	100%
9.5: There is increase in the quality of services provided by the bank to customers.	4	0.74	0	3	29	51	16	99
			0%	3%	29%	52%	16%	100%
9.25: The bank set an indicative target for improvement and continuous development process.	4	0.84	0	9	32	44	14	99
			0%	9%	32%	44%	14%	100%

Table 9 shows that the respondents agree with the statements on people management, especially that there has been an increase in the quality of services provided by the bank to customers (M = 4, SD = .74) and that the employees are satisfied with the working conditions (M = 4, SD = .75).

5.2.7 Customer Focus Scale

The descriptive statistics of the Customer Focus questions are presented in Table 10.

Table 10: Descriptive statistics of Customer Focus Scale (*n* = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
9.11: The employees know their roles and responsibilities in implementation, maintenance, and development of the bank's operations.	4	0.67	0	1	36	51	11	99
			0%	1%	36%	52%	11%	100%
9.12: The bank management listens to the customer complaints and provide an immediate solution.	4	0.75	0	4	37	45	13	99
			0%	4%	37%	45%	13%	100%
9.13: The bank measures the customer satisfactions on the quality of services and operational efficiencies.	4	0.74	0	3	36	46	14	99
			0%	3%	36%	46%	14%	100%
9.14: The bank gives attention to clients' needs.	4	0.80	0	4	36	41	18	99
			0%	4%	36%	41%	18%	100%

From Table 10, employees agree with the statement that they know their roles and responsibilities in the implementation, maintenance, and development of the bank's operations (M = 4, SD = .75) and the bank measures customer satisfaction on the quality of services and operational efficiencies (M = 4, SD = .75).

5.2.8 Continuous improvement Scale

The descriptive statistics of the Continuous Improvement questions are presented in Table 11, and show that many of the respondents agree that the bank has a programme in place to eliminate processes and activities that have become redundant (M = 4, SD = .75) and that the bank provides feedback to customers once a query has been resolved (M = 4, SD = .80).

Table 11: Descriptive statistics of Continuous improvement Scale (*n* = 99)

	Median	*SD*	*1*	*2*	*3*	*4*	*5*	*N*
9.15: The bank gives feedback to clients after resolution of their enquiries.	4	0.80	0	4	36	41	18	99
			0%	4%	36%	41%	18%	100%
9.20: The management has a goal to minimise the cost of different operational processes.	4	0.83	0	6	32	43	18	99
			0%	6%	32%	43%	18%	100%
9.21: The bank has a documentation system that is introduced and applicable for employees in all levels.	4	0.83	0	9	31	46	13	99
			0%	9%	31%	46%	13%	100%
9.22: The bank has processes in place to analysis the activities required to provide excellent service.	4	0.82	0	5	30	44	20	99
			0%	5%	30%	44%	20%	100%
9.23: The bank has a program to simplify the steps required to provide the service to customers.	4	0.82	0	5	43	35	16	99
			0%	5%	43%	35%	16%	100%
9.24: The bank has a program to eliminate the redundant processes and activities.	4	0.75	0	5	33	49	12	99
			0%	5%	33%	49%	12%	100%

Table 11 shows that many of the respondents agree that the bank has a program in place to eliminate processes and activities that has become redundant (*M* = 4, *SD* = .75) and that the bank provides feedback to customers once a query has been resolved (*M* = 4, *SD* = .80). T

5.3 Section C: Factor Analysis

Eight factors were extracted that explained about 68% of the variance in the factor space.

5.3.1 Reliability Analysis of the Questionnaire Dimensions

Table 12 is a summary of the reliability findings.

Table 12: Cronbach's Alpha Findings by Scale

Variable	Factor	Cronbach's Alpha	Number of Items
Leadership (LS)	1	0.91	10
Organisational Performance (OP)	2	0.83	5
Continuous Improvement (CI)	3	0.89	6

Employee Involvement (EI)	4	0.89	7
Customer Focus (CF)	5	0.84	4
TQM	6	0.87	5
People Management (PM)	7	0.86	6
Strategy (STY)	8	0.86	6

Al the scales of the questionnaire yielded Cronbach Alphas of .84 or higher, indicating acceptable internal consistency reliability (Pallant, 2020). This means all the scales can be used in the inferential statistical analysis.

6. ANALYSIS OF REASEARCH QUESTIONS

This study focused on reviewing literature on organisational performance and its relationship with TQM.

6.1 Research question 1

What are the TQM factors that influence organisational performance at the banking organisation?

Based on the findings of the primary research it is concluded that:

Customer Satisfaction: Organisational Strategy: Job Satisfaction Employee recognition, work culture, Leadership [LS], Continuous Improvement [CI], Employee Involvement [EI], Customer Focus [CF], TQM, People Management [PM] and Strategy [STY] influence Organisational Performance. This conclusion is supported by empirical evidence that TQM increases the possibility for organisations to improve organisational performance [14; 6].

6.2 Research question 2

What is the impact of the TQM factors on organisational performance at the South African banking organisation?

Based on the findings of the primary research, it is concluded that if there is any improvement or deterioration of any of the related TQM factors Leadership [LS], Continuous Improvement [CI], Employee Involvement [EI], Customer Focus [CF], TQM, People Management [PM] and Strategy [STY] it will have an influence on organisational performance. This conclusion is consistent with the literature.

7. RECOMMENDATIONS

Based on research findings, the following recommendations are made to banking management as input to their organisational strategy on how TQM can be practised to improve organisational performance.

7.1 Recommendation 1: Customer satisfaction

It was found that although there is a strong focus on customer satisfaction, many of the respondents feel there is room for improvement. Based on this finding, it is recommended that the current processes to improve customer satisfaction be revisited to determine weak points and new processes put in place with the view of improving these customer enhancement processes.

7.2 Recommendation 2: Employee performance interventions

It was found that the characteristics of employees play a role in how they respond to the work environment. Based on this finding, it is recommended that, during the development of an intervention to improve performance, an investigation be conducted of how categories of different demographical characteristics of employees will respond to that specific intervention.

8. MANAGERIAL IMPLICATIONS

Further, according to the research of Adusa-Poku and Anokye [2], efficient use of employee participation has a beneficial influence on perceived organisational performance. People management is one of four TQM aspects that contribute significantly to both operational and financial performance [2]. In a study by Ahmed and Idris [2020] on the relationship between total quality management and long-term organisational success in manufacturing companies in Malaysia, total quality management was found to be a crucial factor as it contributes to the long-term success of the company.

9. CONCLUSION

In the globalised economy, the survival of organisations depends on delivering quality products and services with a focus on exceeding customer expectations. Organisations are going through a shift from a production-oriented focus to a customer-oriented approach. Organisations with a high service quality approach will present a challenge to their competitors, and they will become the benchmark for achieving competitive advantage. However, despite the attention paid by financial services organisations to total quality management [TQM], customers have shown dissatisfaction with the services they receive in most situations. customer focus, people management, and strategy. This implies that if there is any improvement or deterioration in any of these factors, it will have an influence on organisational performance. It is therefore recommended that management of the financial services organisation focus on improving the identified TOM factors to improve the organisation's performance.

ABSTRACT

Project cost is an important performance consideration for new and maintenance building projects. However, due to the high uncertainty associated with heritage building projects, they tend to encounter a higher variability in cost. Thus, budgeting methods that include appropriate risk analysis may improve the likelihood of meeting project cost expectations. The Monte Carlo Method can be used for this purpose since it can provide a confidence level associated with a budget for a specific project. This study investigated the factors influencing project cost overruns, the methods used for preparing budgets and how professionals involved with heritage building restoration perceive the application of the Monte Carlo Method. The study was limited to a single organisation. Still, the findings illustrate that professionals perceive organisational factors to be influential in budget overruns and that even though the Monte Carlo Method is not widely utilised, it could possibly improve budget forecasting.

Keywords: maintenance, heritage buildings, cost, estimate, Monte Carlo Method

* Corresponding Author

1 INTRODUCTION

Heritage building projects differ from other construction projects in terms of concepts, techniques, and procedures when compared to modern construction projects. The uncertainties in heritage buildings are likewise distinct and higher than in modern buildings [1]. Most of the time, the precise work can only be determined after the structure has been opened and dismantled. Due to the challenges in safeguarding the character of such work in terms of its ultimate content, scope, and specification, Nawi *et al*. [1] found that preparing estimates for conservation work is complex and challenging. Poor cost in developing a maintenance budget for heritage buildings might be the key factor in ineffective repair solutions. Therefore, cost is considered one of the most essential attributes and a critical driver of project success [2].

Lazarus and Hauptfleisch [3] suggest that estimating maintenance costs should start with a complete understanding of all expenditures incurred. Thus, costing should include all processes, procedures, materials, skilled specialised labour, and methodologies, including the possible risks. Accurate costing aids in the production of an accurate budget. Therefore, costing methods that promote reliable expectations should be adopted. The Monte Carlo Method may be used to minimise uncertainties associated with maintenance project budgeting methods [4].

Industrial and Systems Engineers aim to utilise engineering tools to among other develop predictions of complex socio-technical systems to achieve the optimal potential [5]. For this reason, this article explores the challenges encountered in the population of budget for heritage building projects and the perception of project managers in using the Monte Carlo Method as a budgeting tool for heritage building projects.

2 LITERATURE REVIEW

2.1 Maintenance of Heritage Buildings

Maintenance is critical for conserving heritage buildings and extending their useful lives [6]. Poor designs may increase building deterioration, faulty construction, maintenance, defective materials, and faulty usage [7]. Au-Yong et al. [8] add that cost creep may also be caused by a lack of maintenance workers, ineptitude, inadequate maintenance equipment and technologies, insufficient maintenance budget allocation, and incorrect maintenance practices. As the number of heritage buildings increases worldwide, their maintenance has become vital to a building’s life cycle [9].

Heritage buildings/structures, unique landmarks worldwide, have particular cultural importance, and the lack of professional maintenance management has proven disastrous [10]. As a result, as Francis et al. [11] say, heritage building upkeep management is vital and must be handled efficiently.

2.2 Principles of Maintenance of Heritage Buildings

Historic structures require different care than modern buildings. Heritage building maintenance, restoration, and preservation must follow specified rules. Building components, for example, must be fixed and conserved in their original state rather than removed and replaced. This is restoration, which is defined as returning a structure to its original state as precisely as possible without adding new pieces to the fabric [12].

This complicates matters since, as Azizi et al. [13] ascertain, heritage building conservation and upkeep are concerned with keeping as much original fabric as possible while differentiating later additions and renovations from the original structure. As a result, conservation permits broad alteration as long as the improvements are aesthetically and historically significant and improve and retain the original structure's character. The instrument or strategy for preserving cultural structures is known as "minimal intervention" and must be followed. This indicates that preserving heritage architectural elements contributes to the preservation of cultural significance by achieving and carrying out maintenance with the least degree of interference. Forster and Kayan [14] ascertain that the main purpose of minimal intervention is to keep deterioration at bay while keeping the building's character and minimising unnecessary disruption. Brereton [15] defines minimal intervention as "as much as necessary", but [16] advises "as little as practical".

There are also specific criteria and processes to follow when maintaining heritage buildings from different nations or areas. English Heritage includes, for example, the goal of repair, the necessity for repair, avoiding unnecessary harm, analysing historical development, implementing established processes, truth to materials, removal of previously damaged alterations, restoration of lost features, and safeguarding the future. Baharuddin et al. [17] suggest that these principles should be seen as needed rules and methods to preserve the building's originality and quality.

It is apparent from the preceding that the supervision and administration of competent and skilled craftsmen or experts are required to maintain and preserve historic structures.

2.3 Challenges in Executing Heritage Building Projects

Heritage projects' difficulties have been witnessed worldwide, including in India, Canada, Finland, Taiwan, the United States, the Middle East, Slovenia, Italy, Israel, Denmark, Austria and England, among other countries. Perovic et al. [18] found in their research in Australia that project managers frequently fail to execute heritage building projects on time, within budget and scope. Both data management and risk assessment are challenging undertakings [19], [20].

Scope Determination

Heritage building projects may also have difficulties since scope determination might be ambiguous [21]. According to Whiteman and Irvvig [22], the problem with the building's user utilisation throughout the maintenance process also presents problems. Albino et al. [23] discovered that most participants in heritage projects in Italy are small firms or small contractors. Mckim et al. [24] recognised unexpected site circumstances, owner-driven scope revisions, design adjustments, procurement challenges, design coordination issues, and regulatory needs in Canada.

Juan et al. [21] discovered that inadequate design information, poor building data, insufficient condition data, and a lack of communication between customers and contractors were all major difficulties in Taiwan. In England, Lee et al. [25] identified the most challenging impediments to be subtle changes and mistakes that are not obvious. Naaranoja and Uden [26] found that the major concerns in Finland were the lack of a decision-making process, scheduling time, clarity of the user's expectations, and risk.

Mitropoulos and Howell [27] found that discovering pre-existing difficulties late in the design process was more prevalent in the United States, tenant-landlord dilemma [28] in Denmark, and failure to record and analyse assumptions in the United States [29].

Resource Constraints

According to Shohet and Perelstein [30], financial constraints influence historical endeavours in Israel. This is obvious in several countries, not just Israel. In their research in Malaysia, Akasah et al. [31] identified a lack of funding for historic project preservation as one of the problems, followed by insufficient management systems, competent individuals, continuous care, shared values, training, and recruiting.

In Lithuania, Dvorak et al. [32] discovered several challenges, including a lack of funds, human resources, time, planned renovation measures, timely documentation, collaboration and communication, different perceptions of the project's goal, changes in politics and policies, a lack of competency, ignorance of benchmarking, and poor management supervision.

Political Influence and Competence

According to Roy and Kalidindi [33], heritage project underperformance may be due to a variety of political, socio-cultural, economic, and technical factors such as urban growth, tourism pressure, a lack of cultural funds, authoritarian governments, improper project selection, corruption, inaccurate conservation policy, and so on. Roy and Kalidindi [33] observed challenges related to agency competency, cost estimating issues, inadequate and unviable documentation, resource constraints, client capabilities, lack of expertise, project stakeholders, and issues in restoring structures to their original state during their research in India.

Inadequate skills among craftspeople have also been identified as a significant issue [34]. Su and Li [35] and Munoth [36] identified that the inability to extract local knowledge could be a significant issue.

As can be seen from the above, heritage projects are riddled with uncertainty, making project management extremely complex. Heritage projects worldwide confront challenges such as time, cost, and poor quality. Furthermore, in their research in Malaysia, Azizi et al. [13] uncovered around 46 problems from previous studies and grouped them into five focal themes to reflect the type of concern: environmental, human, technical, financial, and organisational challenges.

The table below summarises the challenges identified in the literature that impede a Heritage Project's performance.

Table 1: Challenges affecting heritage building projects

No.	Author	Year	Country	Challenges
1	Lee [37] Whiteman and Irvvig [22]	1998	USA	1. The user's usage of the structure during the maintenance process
2	Daoud [21]	1997	Middle East	1. Scope Determination Uncertainty 2. During the execution, the scope may change
3	Albino *et al.* [23]	1998	Italy	1. The majority of the participants are small businesses
4	Mckim *et al.* [24]	2000	Canada	1. Unexpected site circumstances, 2. Owner-driven scope modifications 3. Design adjustments, 4. Procurement issues, 5. Design coordination issues, and 6. Regulatory requirements
5	Shohet and Perelstein [30]	2004	Israel	1. Financial constraints
6	Lee *et al.* [25]	2006	England	1. Errors that are not readily apparent 2. Subtle adjustments
7	Naaranoja and Uden [26]	2007	Finland	1. The absence of a decision-making process 2. Scheduling time 3. Clarity of the user's requirements 4. Risk Evaluation 5. Managing Change

No.	Author	Year	Country	Challenges
8	Juan *et al.* [38]	2009	Taiwan	1. Insufficient design information 2. Totally inadequate building data 3. Insufficient condition data 4. There is a lack of communication between the customer and the contractors
9	Akasah *et al.* [31]	2011	Malaysia	1. Insufficient funds 2. A good management system 3. Skilled personnel 4. Consistent attention 5. Values that are shared 6. Recruitment and training
10	Mitropoulos and Howell [27]	2011	USA	1. Identifying pre-existing problems late in the design process
11	Rahman *et al.* [39]	2012	Malaysia	1. Technical Problems 2. Management and administration problems 3. Financial problems 4. Human behaviour and attitudes 5. Spare parts problems 6. Lack of institutional and training facilities
12	Astmarsson *et al.* [28]	2013	Denmark	1. Tenant-landlord issues
13	Perhavec *et al.* [34]	2014	Slovenia	1. Insufficient skills among craftsmen
14	Gao *et al.* [29]	2014	USA	1. An inability to document and evaluate assumptions
15	Baharuddin *et al.* [17]	2014	Malaysia	1. A lack of maintenance personnel with the necessary knowledge and experience 2. Attack on the Spot or Unplanned 3. The lack of heritage building maintenance guidelines 4. Insufficient financial resources
16	Azizi *et al.* [13]	2016	Malaysia	1. Environmental issues - economic pressure, building conditions, location, business opportunity and third-party interference 2. Human issues - human errors, poor communication between professionals, craftsmen and general labourers 3. Technical issues - limited availability of resources, financial support 4. Financial issues 5. Organisational issues
17	Perovic *et al.* [18]	2016	Australia	1. Project management struggles to fulfil schedule, financial, quality, and scope delivery targets on a regular basis.

No.	Author	Year	Country	Challenges
18	Roy and Kalidindi [33]	2017	India	1. Issues relating to agency competency 2. Estimation issues 3. Inadequate and unviable documentation 4. Restrictions on resources 5. Issues with the client's capabilities 6. A lack of expertise 7. Issues with stakeholders 8. Issues in restoring structures to their original state

From **Table 1**, it can be seen that there are common challenges in different countries. And they can be classified into different categories as follows and demonstrated in **Table 2** using themes [13].

Human Challenges

The human element is crucial and one of the most difficult aspects of heritage project implementation. Inadequate trained staff or artisans, lack of maintenance personnel, bad recruiting, poor communication, lack of competence, human mistakes, and other factors have all been mentioned as barriers to heritage project completion.

Financial Challenges

These problems, which are frequent in many nations, include a lack of cash, inadequate funds, financial challenges and financial limits. This demonstrates that allocating adequate financing for heritage/conservation initiatives remains an issue in many nations. Another crucial component, which is a result of the technical issues discussed previously, is project management to keep costs within budget.

Technical Challenges

Table 2 illustrates that technical concerns make up a higher portion of the obstacles than the other classes/groups indicated above. Insufficient design information, scope determination uncertainty, inability to document and evaluate assumptions, inadequate building data, change management, errors that are not readily apparent, design coordination issues, identifying problems later in the design, issues in restoring structures to their original state, spare parts problems, scheduling time, lack of communication between client and contractors, and lack of maintenance guidelines are all included in this category. These difficulties are a significant factor in the realisation of heritage building projects.

Environmental Challenges

Economic pressures, building conditions, location, and regulatory requirements contribute to these challenges. The majority of participants were small businesses and substantially influenced by third-party interference.

Organisational Challenges

Heritage projects face obstacles from organisations working on them. Opposing conservation ideologies, perplexing rules and guidelines, no standard conservation technique, recruiting and training, concerns linked to agency competency, organisational issues, stakeholder issues, and client capacities are some of the obstacles they face.

The above have been tabulated in **Table 2**, categorising the challenges into themes [13].

Table 2: Categorising Issues in Heritage Projects

Categories/Themes	Challenges
Human	Skilled Personnel Insufficient skills among craftsmen Lack of institutional training Lack of maintenance personnel Recruitment training Poor communication Human behaviour and attitude Weak management and supervision Values that are shared Lack of expertise
	Human errors
Financial	Financial constraints Financial problems Insufficient financial resources Financial issues Estimating issues
Technical	Insufficient design information Scope determination uncertainty Inability to document and evaluate assumptions The user's usage of the structure during the maintenance process Inadequate building data Managing change Technical problems Project management struggles to fulfil project objectives Errors that are not readily apparent Design Coordination issues Risk evaluation Identifying pre-existing problems late in the design process The absence of the decision-making process Issues in restoring structures to their original state Spare parts problems Management and administration problems Scheduling time There is a lack of communication between clients and contractors Lack of maintenance guidelines Inadequate and unviable documentation
Environmental	Economic pressures Building conditions Location Regulatory requirements The majority of participants are small businesses /contractors Business opportunity and third-party interference

Categories/Themes	Challenges
Organisational	Opposing conservation philosophies Confusing laws and guidelines
	No standard method of conservation Recruitment and training Issues relating to agency competency Organisational issues Issues with stakeholders Issues with client capabilities

2.4 Costing in Heritage Building Projects

Cost is regarded as one of the most important factors influencing project success. Among other things, poor cost performance has been a key cause of concern for all stakeholders in new construction and maintenance projects. Devi and Ananthnarayanan [2] argued that projects frequently face cost overruns or escalation that raise the project budget. According to Odeck [40], potential cost overruns should preferably be determined during the planning stage when the design, scope, specification, and ultimate cost are all created.

As previously mentioned, historic projects differ in concepts, techniques, and procedures compared to new building projects. The typical hazards associated with heritage building projects also differ from modern buildings. Costing should incorporate all processes, methods, materials, specialised labour, methodology, and potential risks to meet expectations.

Nawi et al. [1] argued that preparing estimates for conservation work is complex and difficult due to the difficulties in preserving the nature of such work in terms of its eventual content, scope, and specification. The precise task is usually only established after the structure has been opened and destroyed. Because the fabric of the heritage building is culturally significant and should be conserved to the greatest extent feasible, the present building's structure is one of the most crucial criteria in deciding the project's ultimate cost. Mahmoud et al. [41] define heritage building maintenance as "restoring the building fabric as nearly as feasible to the original using traditional techniques and matching materials while being mindful of the original structure". Mechanical and electrical services, on the other hand, are typically expensive due to the complexity of the existing systems. The lack of a clear and precise way of evaluating heritage building maintenance expenses, according to Mahmoud et al. [41], makes it difficult for historical building custodians and owners to design maintenance budgets and financial plans for managing heritage building restoration.

3 METHODOLOGY

The research used a convenience and judgemental sample [42] that was based on one organisation that manages over 704 building properties, of which 351 buildings are listed as heritage buildings. Before data was collected, the authors applied and received ethical clearance from the research institution, and all respondents provided informed consent. Secondary data collected was based on the conservation projects carried out in recent years. About 14 conservation projects were executed and completed between 2011 and 2022. The projects are listed in

Table 3, named A to N. The fourteen projects were executed on buildings which were 60 years old. Three conservation projects were further selected for case studies, whereby the team members who worked on each project were interviewed using semi-structured interview questions. The targeted team members in these case studies were those who were involved in budget preparations and managing project costs until completion.

Projects C, G, and H were chosen for case studies. These heritage-building projects were chosen based on the availability of team members from the organisation who had previously worked on similar projects. Budget overruns also happened on these projects.

Table 3: Criteria for projects selected for the case study

No.	Criteria for selection	Projects		
		C	G	H
1	Heritage building project	√	√	√
2	Budget overruns	√	√	√
3	Completed project	√	√	√
4	Availability of project team members	√	√	√
	Suitability for this study	Yes	Yes	Yes

4 RESULTS

Table 4 shows the secondary data for the heritage building projects. The data set includes 14 heritage building projects completed between 2011 and 2022. The most notable aspect is that the projects had cost or budget overruns ranging from 5% to 180%. This illustrates the high amount of budget uncertainty associated with heritiage restoration projects.

Some of the oldest buildings experienced the biggest budget overruns (see **Table 4**). For example, Project A involved a building that was 107 years old at the time of the study and experienced a cost overrun of 180%. Project K, a building that was 91 years old, had a cost overrun of 87%. A 137-year-old building from Project M had a cost overrun of 60%, and an 82-year-old building in Project C had a cost overrun of 43%.

Table 4: Heritage buildings executed

Project Name	Construction Date (Year)	Building Age (Years)	Original Maintenance Budget (ZAR)	Final Amount (ZAR)	Cost-Overrun (ZAR)	Cost-Overrun (%)
A	1915	107	3 850 000.00	10 789 373.22	6 939 373.22	180%
B	1930	92	13 600 000.00	16 430 409.27	2 830 409.27	21%
C	1940	82	6 500 000.00	9 317 117.83	2 817 117.83	43%
D	1957	65	15 100 000.00	16 756 196.53	1656 196.53	11%
E	1957	65	28 399 000.00	38 648 368.16	10 249 368.16	36%
F	1960	62	32 000 000.00	35 382 984.28	3 382 984.28	11%
G	1926	96	25 000 000.00	33 035 020.15	8 035 020.15	32%
H	1925	97	51 000 000.00	53 556 409.22	2 556 409.22	5%
I	1956	66	102 570 162.68	113 267 986.07	10 697 823.39	10%
J	1946	76	12 500 000.00	16 235 830.77	3 735 830.77	30%

Project Name	Construction Date (Year)	Building Age (Years)	Original Maintenance Budget (ZAR)	Final Amount (ZAR)	Cost-Overrun (ZAR)	Cost-Overrun (%)
K	1931	91	3 500 000.00	6 553 457.00	3 053 457.00	87%
L	1940	82	16 000 000.00	17 052 489.98	1 052 489.98	7%
M	1885	137	800 000.00	1 283 398.18	483 398.18	60%
N	1921	101	16 607 975.00	18 359 612.04	1 751 637.04	11%

Professional Careers, experience and time, worked in the institution

Table 5 illustrates the personal background of the three experts that were interviewed. Each of them worked on populating the budget for these projects and was part of the professional team that worked on them until their completion. Their experience is mostly 10 to 15 years, while the other three have more than 20 years of working experience. Most have worked in this organisation for between 5 and 10 years except for two project managers who worked below five years. The interviewed professionals were Project Managers, Quantity surveyors, and Architects.

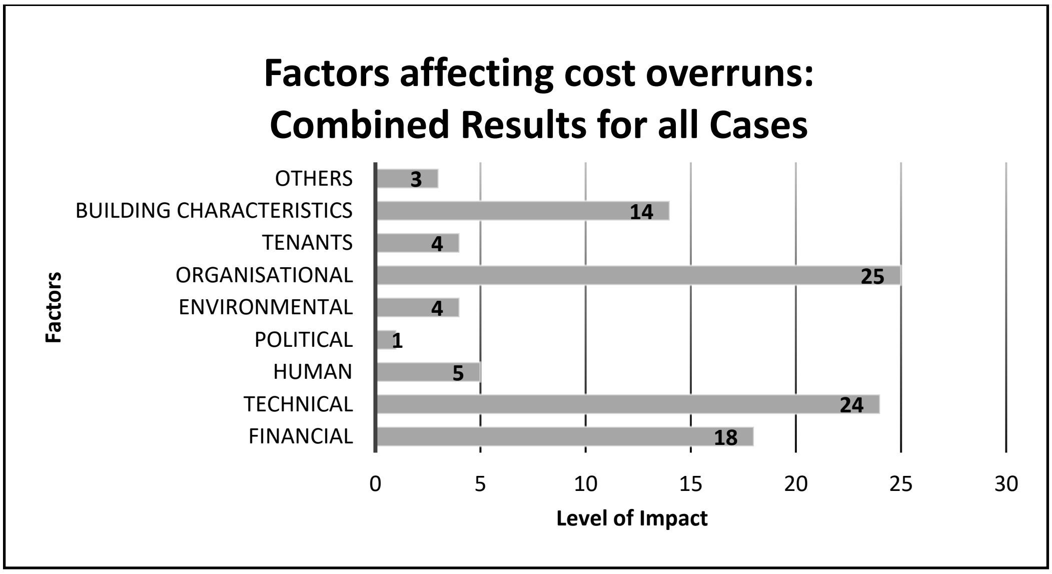
Table 5: Interviewed professionals with experience and years working at the entity

Professional Careers	No. of Professionals	Experience (Years)	Years Worked in the Organisation
Project Manager[1]	3	> 20	5 - 10
Project manager[2]	2	10 - 15	< 5
Quantity Surveyor	2	10 - 15	5 - 10
Other (Architect)	2	10 - 15	5 - 10
Total	**9**		

Factors affecting cost overruns

The interviewees were requested to rate the influence of nine factors affecting cost overruns. A six-point Lickert Scale from 0 to 5 was used. The results indicate that organisational factors were believed to have the most influential impact on project performance (see Figure 1, which illustrates the sum of all the ratings gathered) and, after that, technical factors. Financial factors followed this and then building characteristics. Political factors were considered to have the lowest influence, and human, environmental, tenants, and other factors were considered to have a low influence.

Figure 1: Factors affecting cost overruns (combined results)



Methods used to populate budgets for heritage building projects

The response from the three case studies shows that the professionals used two methods, namely, the elemental estimate method, which also goes with assessing the condition of heritage buildings and the parametric method, using the area method (rate/m^2). They used these estimating methods because they are familiar, quicker and easier to use.

Monte Carlo as a tool for budgeting for heritage building projects

Most of the respondents indicated that they were unfamiliar with Monte Calo Method and were provided with an Open Source Excel Monte Carlo Simulation model [43] to evaluate its capabilities. They indicated that it caters to uncertainty and can therefore be more appropriate for budgeting on heritage building projects.

Monte Carlo Simulation compared with the used estimating techniques

Under this question, the respondents were asked to rate any method they used with the Monte Carlo Method with a rating from 0 to 5, as shown in Figure 2.

Figure 2: Discrpitor rating

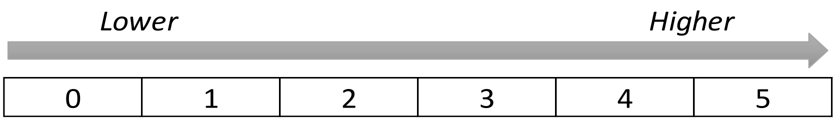


Figure **3** illustrates that the majority of the respondents rated the Monte Carlo Method either three or four out of five, which is higher than the median and thus demonstrates that the respondents, in general, believed that the Monte Carlo Method would be better at preparing budgets than the tools they have historically utilised.

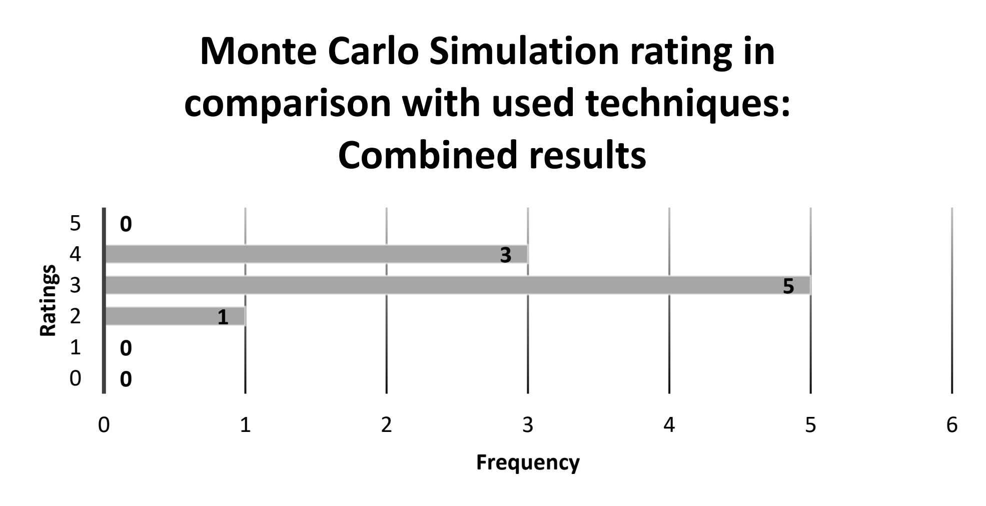
Figure 3: Rating Monte Carlo Method in comparison with used methods



5 FINDINGS

Heritage building projects encounter budget overruns. The 14 heritage building projects considered for this study experienced budget overruns between 5% and 180%. Uncertainty contributed to an increase in project budget overruns. This confirms that heritage building projects are faced with a high amount of uncertainty. Even though not statistically significant, it appears that the older the building, the higher the probability of considerable budget over expenditure.

The respondents indicated that Organisational challenges had the most influence on project performance. After that, Technical aspects were considered to have a substantial impact.

To generate the budgets for heritage building projects, project managers are most comfortable utilising an elemental estimate and parametric approaches (rate/m^2). They found the procedure to be simple and quick to implement. Most project managers in this organisation were unfamiliar with the Monte Carlo Method.

6 CONCLUSION

Scope determination uncertainty, change in scope, inadequate building data, insufficient design information and spare parts problems cause difficulties in preparing a budget for conservation projects. The budget can also be influenced by a lack of heritage building guidelines, issues in restoring structures to their original state, tenant-landlord issues, and identifying pre-existing problems late in the design process. The three case studies demonstrated that organisational issues and technical issues are prevalent.

Project managers preferred the elemental and parametric methods (rate/m^2) when preparing budgets. However, project managers indicated that they expect that using the Monte Carlo Method could assist them with preparing budgets that will provide a better representation of the uncertainty associated with heritage projects. By adding this piece to their toolkit, industrial, systems and engineering managers can provide optimised solutions to complex socio-technical puzzles.

7 RECOMMENDATIONS

The study only considered projects that had already been completed without using the Monte Carlo Method when the project budget was prepared. However, it indicated that the Monte Carlo Method could possibly assist with illustrating uncertainty associated with projects and that this could assist with creating more realistic expectations of projects' financial performance. For this reason, it is recommended that more project managers are trained to use the Monte Carlo Method and that more research is performed to evaluate how it influences project budgeting and performance.

The study was performed within one department of a single organisation. The external validity of the research may be improved by adding additional case studies.

ABSTRACT

Graphene is a recently discovered super material that will most certainly play a big part in the future of manufactured products and nanotechnology. The main limitation to its total takeover of the market, however, is scalability and efficient production. Due to this, not many countries have started producing their own graphene, including South Africa. In this paper, a sustainable graphene production methodology for South Africa is designed for the mass production of graphene through plasma-enhanced methods, due to promising scalability. Waste management becomes a core issue in South Africa with regards to plant design. A systematic literature review explores the core design considerations and capabilities of graphene production in South Africa by means of plasma-enhanced methods. The applicable Sustainable Development Goals are also considered during the analysis. This study exposes the core competencies for graphene production in South Africa and similar developing countries.

Keywords: Graphene, Sustainable Development Goals, Plasma, Waste Management

1 INTRODUCTION

1.1 Background

Graphene is known as a wonder-material and is undergoing an immense amount of research in a variety of fields today. It was discovered in 2004 and has since been a buzzword throughout many of the different science and engineering disciplines, with many research papers on the topic being released each year.

Graphene is a one-atom-thick sheet of carbon atoms arranged in a honeycomb-like pattern, often referred to as a two-dimensional material. It is the strongest, thinnest, lightest, and most conductive material of both electricity and heat known to man [1]. The capabilities of the material are seemingly endless, and it can be used to shape the future of mankind. South Africa has much to gain from producing its own graphene, since the material is soon to be widely used across many industries and the market is still in its early development.

Graphene is produced in a few countries today, including the United States, the UK, Spain, and China. Most other countries are not producing graphene since they are either still in the early stages of utilising this new technology or have not acquired such technology due to the immense challenge of mass-production. This includes South Africa, which currently has no large-scale graphene production facilities.

Graphene has the potential to further development in a wide range of industries due to its valuable characteristics, especially in terms of nanotechnology, where graphene powder is often used to strengthen polymers. Other uses include biomedical applications, energy storage devices, conductive inks for printed electronics, graphene-based separation membranes and more [2].

The current methods of producing graphene are extremely costly and still developing in terms of efficiency, with most methods generally yielding small amounts of graphene or simply having too high operating costs [3]. According to Dasari et al. [4], the most popular methods that have been developed for graphene production are: Chemical exfoliation of graphite and chemical vapor deposition methods (CVD). These production methods have both been scaled up to a certain degree to produce graphene in larger quantities.

Plasma-enhanced chemical vapour deposition (PECVD) is a type of CVD that enables graphene to be produced more efficiently and at a lower cost than with normal CVD. Inductively Coupled Plasma (ICP) is one popular form of conducting PECVD. PECVD also shows promise of being much more scalable than other known methods [3]. In addition to this, PECVD and other plasma-related graphene production methods allow for the use of low-cost, carbon-containing solids as precursor material, which means that waste material or biomass can be used in production, making the process sustainable to the environment as shown by Ye et al. [5]. This addresses yet another problem South Africa, as well as the rest of the world, is currently facing, namely the efficient use of waste and combatting waste build-up. PECVD is, however, still not an optimal graphene production method since it still requires a high amount of energy and takes time. Thus, further research towards a more efficient graphene production method is still required.

Another issue that needs to be considered is whether South Africa in its current state will be able to maintain or fund the production of graphene, despite the undoubtable benefits of graphene production.

The 17 sustainable development goals will be taken into consideration when conducting this research.

In summary, the following problems currently exist in the graphene industry: Graphene production often incurs high costs and energy usage, whilst also not guaranteeing quality graphene based on the production method used. Graphene is extremely costly even though it has become more affordable in recent time. An optimal graphene production method has yet to be discovered. Successful implementation of a graphene production can thus be a great source of income for the development of the South African economy. For this to realise, it is pertinent that the essential factors are well understood. For example, graphene production scalability still needs to be improved. South Africa has many flaws that might stand in the way of successful graphene production. A deep analysis of the current state of the country is needed. This is important, as South Africa is still a developing country, currently struggling due to the power crisis at hand.

1.2 Research problem

Graphene is a resource not yet tapped into by the South African economy, and the scalability of graphene production in a sustainable manner is one of the greatest challenges in the graphene industry.

1.3 Research aim and objectives

The aim of this study is to establish the conditions for sustainable graphene production in South Africa.

To achieve this, the following objectives are set out:

1. Research graphene production methods, specifically PECVD, as well as how it can be upscaled for mass production
2. Conduct a systematic literature review (SLR) to explore the current state of graphene production
3. Categorise the conditions for sustainable graphene production in South Africa
4. Align the results from this study with those relevant to the Sustainable Development Goals (SGDs)

2 RESEARCH METHODOLOGY

A systematic literature review (SLR) is conducted to answer specific research questions regarding graphene production in South Africa. The general structure of this SLR was formulated by using the SLR conducted by Maisiri et al. [6] and Mangaroo-Pillay [7].

The main aim of this systematic literature review is to evaluate whether the PECVD graphene production method is the best, most scalable, option for the synthesis of graphene. The information obtained will also give insight regarding the extent to which graphene production can be conducted in a sustainable manner. This is to ultimately determine the conditions for graphene production in South Africa. Information is also gathered on the applications of graphene, as well as how often the different types of graphene production are used or mentioned.

2.1 Inclusion and exclusion criteria

The following inclusion and exclusion criteria were formulated and used to identify which of the obtained research papers were to be deemed important for further research.

Table 1: Inclusion and Exclusion criteria

Criteria type	Criteria	Description
Exclusion	Duplicate papers	Paper appears more than once throughout the search
	Full text not available	Not able to retrieve the full text version of the paper

Criteria type	Criteria	Description
	Paper not relevant	Not related to search criteria, or ICP found, but not as an acronym
Inclusion	Partially related	One of the search terms mentioned, whilst discussing potentially useful information
	Closely related	Both search terms mentioned, whilst discussing useful information

2.2 Search strategy

The following search string was applied: "Graphene production" AND ("PECVD" OR "ICP"). utilised to prevent any plasma-related graphene production method from being left out of the search results. These terms were used in a Boolean search string to increase the probability of the search returning relevant research papers, which was demonstrated by Aliyu [6].

In order to effectively gather as much relevant information as possible, the search was conducted on three different scientific journal databases, namely Sciencedirect, Scopus, and Web of Science. Note that no specific time frame was applied since graphene is still a relatively new subject of research with many well-established production methods.

2.3 Study selection

The papers selected for this systematic literature review were obtained and filtered by using the inclusion and exclusion criteria shown in table 1. Figure 2 shows the exact steps followed to obtain the results in the form of a flow diagram. This diagram also shows the exact number of papers used in the final SLR.

Firstly, the search string mentioned in 2.3 was applied to ScienceDirect, Scopus, and Web of Science. After obtaining all the results, a scan was conducted to check if any of the papers might have appeared more than once across the different databases.

Next, each result was analysed to check whether the full text versions were available. If so, the papers were reviewed to check if the search terms were correctly featured, and whether they contain useful information.

In many cases where "ICP" was identified by the search algorithm it would not be due to the use of the acronym, but rather at parts of a sentence containing "atmospheric pressure", highlighting the end of the first word, and the beginning of the latter. This was a frequent occurrence, and papers containing this search result usually did not have any relation to plasma-enhanced graphene production and were thus discarded.

The papers that were not discarded due to the exclusion criteria to this point were thus classified as relevant to the study. These papers were analysed further to group them into different categories, with only few being discarded at a later stage upon further inspection.

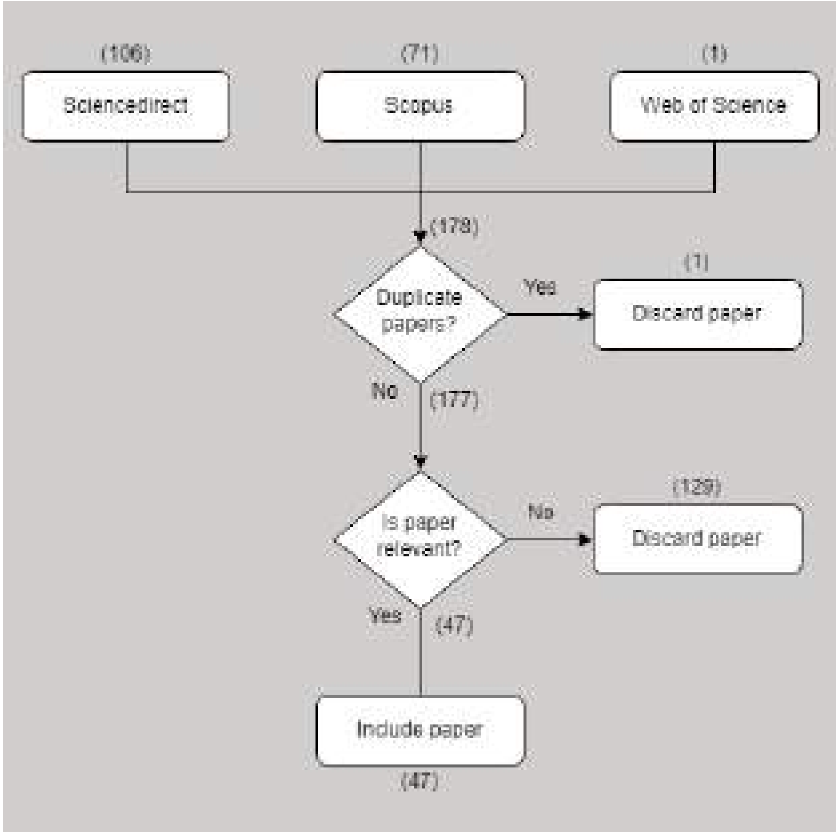

Figure 1: Systematic literature review flow diagram

2.4 Data collection and analysis

Any paper that discussed or mentioned graphene production was analysed to see in what manner they can provide more information. Papers used thus ranged from different categories such as: Scientific experiments where graphene was produced and its quality analysed, research projects where the sustainable use or production of graphene was investigated, reviews on the applications of different types of graphene, synthesis studies where graphene was synthesised on different substrates, and studies where different graphene production methods were compared.

The papers deemed important were each analysed qualitatively and categorised based on the information they contain in Appendix A. These categories are discussed further in section 2.7.

These papers are used to justify the use of PECVD graphene production and to decide whether graphene can be used and produced reliably in a sustainable manner. It also explores whether PECVD graphene production can be carried out on a large scale. Much insight was also gained regarding other plasma-related graphene production methods that have emerged in recent time.

3 FINDINGS

Different results have been formulated from this research. The first set of data pertains to the SLR full paper qualifiers. These appear in Appendix A. These papers are further analysed by presenting several discussion themes in Section 3.2.

3.1 SLR publications

A total of 178 papers were obtained from the three academic databases. From this dataset, one paper was a repetition and 129 were excluded after falling outside the inclusion criteria.

Ultimately, 47 papers were selected for full text reading. The prevalent themes were CVD, PECVD, other plasma-related graphene production methods, waste material usage, scalability of graphene production, graphene applications, comparing graphene production methods, and sustainability.

From these papers, Figure 2 showcases the number of papers per year that were produced. It shows a steady increase in publications as time progresses, indicating that Graphene is becoming more and more relevant.

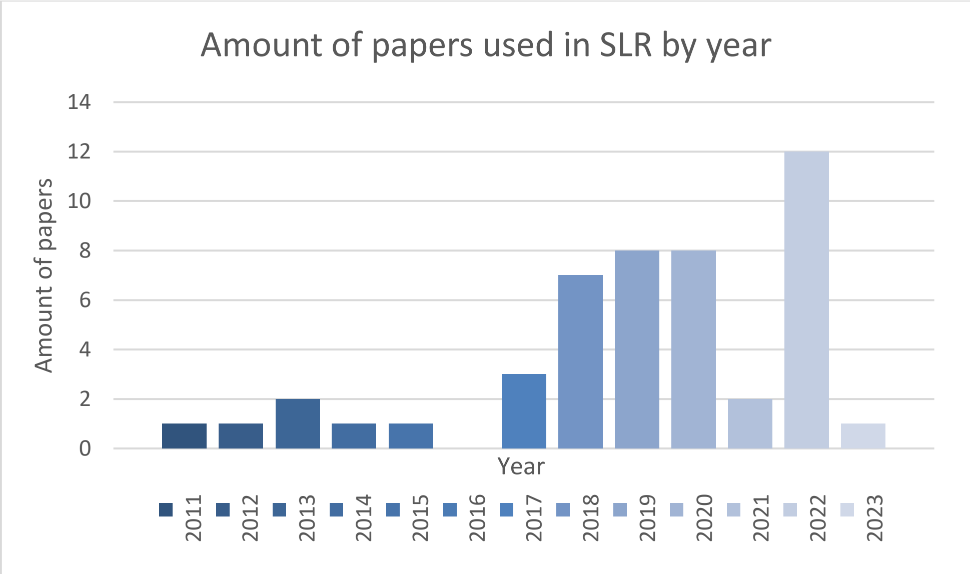

Figure 2: Bar chart of number of papers per year

3.2 Discussion of prevalent themes used to classify papers

3.2.1 PECVD

The paper in question focuses on the PECVD method for the production of graphene or researched the method and communicated findings.

PECVD is an established method of graphene production, and the goal is to include it as the method used in the methodology to be designed, since it is also seen as the most cost effective and scalable method for mass production.

PECVD is used to produce thin films of graphene, and it is preferred to normal, or thermal, CVD due to its lower operating temperatures. A plasma consisting of ions, electrons and some neutral species in both ground and excited states is used in this process. These plasmas are then ignited by means of a high frequency voltage applied to a low-pressure gas. Inelastic collisions then take place within the plasma between electrons and gas molecules, forming excited neutrals and free radicals, as well as ions and electrons. PECVD deposits thin films at lower temperatures by taking advantage of these reactive species [54].

3.2.2 CVD

The papers [13-14, 20-21, 26, 38] place a primary focus on CVD for graphene production.

CVD is often seen as the best graphene production method of graphene, since it has undergone the most research and produces good quality large-area graphene films. CVD is the precursor to PECVD, meaning that both methods produce the same product. CVD is often used as an umbrella term to cover all the different types of CVD that have been developed from the base method, with PECVD only being one of them.

CVD is popular because of its excellent quality products, as well as its enormous potential for scalability. It is, however, in its normal form not a very cost-effective method and is thus not considered for the methodology, but rather its popular derivative in PECVD.

3.2.3 *Various graphene production methods*

Several papers [4, 7, 9-12, 15-18] discussed multiple methods of graphene production. These papers place focus not only on one graphene production method but research many different methods to compare the types of graphene they can be used to produce, or to compare their effectiveness.

These methods can range from chemical exfoliation, CVD, PECVD, Plasma-related graphene production methods, and epitaxial growth. These methods are each useful for the synthesis of different types of graphene products or structures and are thus all researched for their possible improvement or usage.

3.2.4 *Applications of graphene listed*

Certain studies [1-2, 4, 11, 15-18] listed how graphene can be used, whether it be focussed on one specific application, or multiple based on different types of graphene products. Graphene is known to have many different applications, form electronic engineering applications to the biomedical industry, and many papers focus on identifying more new possible applications or refining existing applications.

The various applications of graphene include high frequency transistors, touch screens, solar cells, high-power LEDs, graphene-polymer nanocomposites, clean energy devices, sensors, and field effect transistors.

These are only a few of the currently known applications, and many more will be identified as research continues and graphene becomes more common worldwide.

3.2.5 *Plasma-related graphene production methods*

Many papers [3, 20, 29, 32] had a focus on other plasma-related graphene production methods, showcasing the value of plasma when it comes to the production of graphene. In these papers, plasma torches are usually used in different ways to produce graphene without CVD or other basic production methods.

Plasma-based graphene production is also undergoing immense research and has shown that it can be applied to larger scales to produce graphene of an acceptable quality. Papers containing these results were analysed to compare whether these processes may be more viable than PECVD.

While these methods of graphene production show great merit for producing the material, they are not yet developed to the point of being considered as a scalable method for the mass production of graphene in the same way as CVD methods. For example, the high operating and energy costs incurred make graphene costly and ineffective. They are, however, useful for producing certain types of graphene other that the films produced through CVD methods, like graphene powder, graphene flakes, carbon nanotubes, and vertically oriented graphene.

3.2.6 *Mass production*

Many research papers [14, 16, 18, 21-22] were listed under the category of mass production due to them paying great attention to the possibilities of scalability in the graphene production industry. PECVD or other types of CVD were most commonly mentioned as methods for graphene production at a large or industrial scale.

Mass production is currently one of the main research problems in the graphene industry, and scientists are working hard to find more efficient ways of producing graphene at a large scale.

There was significant evidence in the papers that this is being improved for certain graphene production processes.

The mass production of graphene will undoubtedly spark a great shift in the global economy, as many countries and large corporations are patiently awaiting the arrival of more sustainable, cost-effective methods of graphene production. Graphene will be adopted in many industries, from electronics to aeronautics and biomedicine. It will truly be the material the future is built upon, and it might even be the material to take mankind to Mars.

3.2.7 Sustainable Development Goal alignment

A significant portion of the papers [3, 4, 7, 9] mentioned that graphene has many possible sustainable applications, especially in wastewater treatment, where graphene was used to filter impurities from contaminated water.

Other sustainable uses of graphene include graphene production by using waste materials, which can be of great use for waste management applications.

During this study, it was found that the categories can be linked with some of the SGDS. More specifically, goal numbers eight (Decent work and economic growth), nine (Industry, motivation, and infrastructure), and twelve (Responsible consumption and production) are very important with regards to the application of graphene in South Africa.

In terms of decent work and economic growth, the commercialisation of graphene will most certainly create more job opportunities upon being more commercialised, which is of great importance to South Africa considering the high level of joblessness in the country. Graphene is also in high demand, and this demand is sure to only increase with time, meaning that any country within the industry has the opportunity to grow their economy by producing and exporting the material. The graphene industry can set an example to other production companies of what sustainable production should look like by means of incorporating sustainable production methods and power sources into their daily operation.

With regards to Industry, motivation and infrastructure, graphene will lead to great changes in how many products or structures for infrastructural needs are developed. Graphene's light weight and strength will be used in many different applications, which could include housing and the design of other structural materials. Graphene production facilities will also be able to function sustainably by means of using waste material for the synthesis of graphene, whilst using minimal energy sources. Renewable energy can also be used as a primary source of energy for such facilities, further emphasising sustainability. Graphene is currently also developing and promoting research in a number of different fields, which is another target of this goal. (Mention biomedical application again)

As for responsible consumption and production, measures can be put in place and prioritised to effectively manage all waste from graphene production. Waste management strategies will incorporate the use of graphene production to process certain types of wastes that can be used to produce graphene, reducing the burden of waste on mankind. Graphene production methods can be optimised to minimise waste produced during production. Finally, the limited resources on earth must be carefully considered when designing facility infrastructure, all the way to the operating processes taking place within the production facilities. Any prospective graphene producer must take into account the immense potential uses of graphene production facilities to improve sustainability worldwide.

3.2.8 Reflection on the results

Appendix A shows that many papers tend to discuss more than one graphene production method in somewhat detail. The papers listing many different production methods usually also listed many applications of graphene and discussed how the different production methods can be used in unique ways. 40% of the papers used for this SLR focus primarily on PECVD, with many of the others giving mention to it. The other bulk of the results, however, clearly indicate that many studies have been conducted to produce graphene by means of PECVD. A small portion of the results were focussed on normal CVD or a variety of different CVD methods in one paper.

Other plasma-related graphene production methods also appeared frequently throughout the results, giving insight regarding in what other modes plasma can be used to produce graphene. The plasma-related graphene production methods are often very sustainable, with most of them utilising waste material or other forms of sustainable materials to produce graphene at a low temperature, confirming that these methods can also be used successfully for graphene production. These methods are, however, not recognised to the degree that an established method like PECVD or normal CVD is recognised.

Furthermore, the research conducted confirms that graphene can in fact be used or produced sustainably, especially with regards to waste management, which is one of the core goals set out for sustainable graphene production in South Africa. A popular sustainable use of graphene that appeared multiple times was the use of graphene in wastewater treatment. This can be especially useful in many developing countries like South Africa for more reliable sources of water for rural communities.

Other uses of graphene that were identified include the design of different types of highly effective sensing devices and equipment, the use of graphene films as screens for devices with digital displays, the strengthening of materials through graphene oxide powder, energy storage devices, and even water desalinisation.

It is important to note that most papers, whether they cover the production of graphene through various methods or one specific method, mention that CVD or PECVD is widely considered as the most effective way of producing high quality graphene at a large, or industrial scale. The only downside is that the process is costly, but the advantages of the different PECVD methods over normal CVD and other graphene production methods are too significant. PECVD is also undergoing constant research and improvement, making it the most viable option for graphene production regardless of cost.

The improvement if PECVD is mostly centred around reducing the required energy by decreasing operating temperatures and using the most efficient source material to produce graphene sheets.

4 DISCUSSIONS AND CONCLUSION

This study highlights the fact that graphene is an emerging material of great value and will surely be one of the main building blocks for the future of humankind. A systematic literature review yielded results showing that Plasma-Enhanced Chemical Vapour Deposition is currently seen as the most effective graphene production method, and that graphene can also be used or produced sustainably, further emphasising its usefulness in modern society. Graphene is an untapped market, and countries will soon start producing their own graphene. This knowledge validates the need for graphene in South Africa since the economic benefits of graphene production could be immense.

Future research could explore the detailed costs of implementing a graphene production facility making use primarily of PECVD for graphene production. This could then be used to gauge how accessible graphene currently is worldwide, which can be done by conducting a Monte Carlo simulation taking into account the various contributing factors. Further research with regards to the sustainability of graphene could constitute researching the specific types of waste material that could be used to produce graphene, or how graphene production could be used for waste management. Finally, scalability the scalability of graphene production, specifically through PECVD, could be researched further to draw better conclusions regarding its imminent adoption.

South Africa is a diamond in the rough, a country of great value with challenges in the form of social problems and technological issues. These challenges block the path to imminent greatness and are slowly being broken. Similar to South Africa, graphene is a material of immense value to humanity on the brink of a breakthrough. Just as the visionaries who have brought South Africa to where it is now dug deep to bring change, scientists had to isolate graphene from graphite to reveal its true potential. If we consider scalability and efficiency as puzzle pieces, the key to breaking the boundaries of graphene is placing together these puzzle pieces correctly in order to reveal sustainable Graphene production in South Africa.

ABSTRACT

Maintenance personnel and asset care managers need to understand how maintenance contributes to the organisation's business objectives. The effectiveness of a maintenance strategy can only be determined if it can be identified and evaluated as a given maintenance strategy. Organisations measure maintenance performance to remain competitive, identify existing gaps, indicate improvements, and run cost-effective businesses. In situations where operational costs remain high and maintenance costs persist, implementing the maintenance strategy is ineffective. However, using financial data alone is inefficient and does not reflect maintenance performance. This paves the way for the introduction of additional measurement methods. This study followed a systematic literature review to collect data and create new concepts. A maintenance strategy measuring framework is developed to help rail maintenance practitioners measure the effectiveness of their maintenance regimes. The developed framework enables practitioners to identify gaps for improvement.

Keywords: maintenance, key performance indicators,

* Corresponding Author

1 INTRODUCTION

Maintenance personnel and asset care managers have a crucial role in contributing to an organisation's business objectives [1], [2]. Extensive research has been conducted on maintenance performance measurements, aiming to examine the impact of maintenance strategies within organisations. Breakdowns and downtimes significantly affect plant performance [3], [4]. As stated by Raouf et al. (2006), it is essential to identify and evaluate a given maintenance strategy to determine its effectiveness. In today's competitive landscape, organisations measure maintenance performance to remain competitive, identify gaps, drive improvements and ensure cost-effective operations. [1], [6]–[8]. Traditionally, financial data has been used to measure performance, aiming to reduce operating costs while optimising maintenance expenses [9]. However, relying solely on financial data proves inefficient and fails to provide a comprehensive assessment of maintenance performance. This paves the way for alternative measurement methods, such as balanced scorecards and intelligent systems [10]. A comprehensive performance measurement system encompasses both financial and non-financial metrics, as well as soft and hard metrics [10], [11]. Soft metrics include factors like employee attitude, which are important to consider in assessing maintenance performance. The study of maintenance performance measurement holds significant importance as it challenges the notion that maintenance is simply wasteful, as some managers claim [1], [12]. Nevertheless, Lundgren et al. [13] stated that quantifying maintenance strategy effectiveness is challenging, leading researchers to develop various models and frameworks for quantification.

2 LITERATURE REVIEW

Researchers have proposed several performance maintenance measurements. Some of the proposed measurement methods are generic, whereas others are specific to the manufacturing, energy, and aviation industries. For example, according to Peach et al. [14], maintenance performance can focus on various aspects such as equipment performance, cost performance, process performance, and maintenance function. However, the method proposed by Kang et al. [9] states three categories that need to be established to measure maintenance performance are key performance indicators (KPI), measurement system and metrics.

According to Parida et al. [1], some researchers consider a metric to be a unit of measure. In this case, the measure refers to specific observations characterising performance, whereas the performance indicator is a defined variable. However, despite extensive research, the industry's application of these measurement models, frameworks, concepts, and strategies is limited. Consequently, it remains challenging to quantify the effectiveness of maintenance strategies, signifying a gap between research and practice [13].

2.1 Measurement system

A measurement system can be defined as a set of metrics used to quantify the effectiveness and efficiency of an action [1], [15]. This includes a balanced scoreboard. According to Kumar et al. [6], measurement systems help to identify and integrate four aspects: financial, customer, internal business, and innovation. Before the advent of balanced scoreboards, maintenance performance was mainly based on financial measurements. Maintenance measurement systems are mainly divided into models and frameworks. A framework helps identify boundaries and set up dimensions and relationships among dimensions [16]. In the nonfinancial performance measure, the focus when considering relationships is generally on quality, profitability, effectiveness, efficiency, and survival for growth [16].

Peach et al. [9] proposed a maintenance performance measurement framework that included human aspects . These included knowledge, skills, abilities, and personal characteristics, which are known as competence elements. Maintenance work quality, efficiency, and effectiveness rely on the maintenance workers performing maintenance activities. Phogat and Gupta [17] further emphasised the importance of the level of skill of personnel and the availability of resources. Therefore, human factors should not be ignored in maintenance performance measurements, as they ensure safe, effective, and efficient system performance.

2.2 Key Performance Indicators

According to Kumar et al. [6], maintenance performance first requires the identification of indicators. Performance indicators highlight an organization's deficiencies and help determine the root cause [1]. In the manufacturing industry, KPIs are variables used to reflect on the operational performance. KPIs are used to evaluate the effectiveness of a carried-out activity, and the best method is to consider KPIs that are specific to the organization [16], [18]. When properly utilised, KPIs should highlight company improvement opportunities [19]. Examples of KPIs include efficiency, throughput, availability, productivity, and product quality. Therefore, KPIs are a set of quantifiable variables within a maintenance measurement system that reflects an organization’s performance [6], [9]. However, it is difficult to measure everything that is associated with maintenance. Therefore, it is essential to select what is considered critical for meeting an organization’s objectives.

An example is the manufacturing industry, in which meeting production goals is deemed critical. Therefore, measuring the availability is ideal in such cases [6]. In addition, the European standard BS EN:15341 (2007) [20] for maintenance performance KPI, provides three indicators: economic, technical, and organisational [6].

Researchers have used performance indicators to measure maintenance effectiveness and compare actual conditions to specific preference conditions [6]. Researchers have also argued for the importance of analysing the relationships between different KPIs. This is because KPIs affect one another; therefore, knowing which influences the other is critical. Several KPIs have been identified, some of the KPIs identified by Kumar et al. [6] and Ku and Kim [16] are customer satisfaction, cost, equipment, maintenance safety and environment, employee satisfaction, downtime, change over time, planned maintenance tasks, unplanned tasks, number of new ideas generated, skill, number of training, failure rate, equipment availability, improvement training, quality returned, and employee complaints, respectively. Metrics for maintenance performance are essential in an industry, as they help develop corrective actions and guide steps to meet organizational objectives. According to Wijesinghe and Mallawarachchi [7], the availability of spare parts and the frequency of purchases can be used to measure maintenance performance and calculate the amount spent on maintenance. According to Parida et al. [1], performance indicators can be divided into categories: economic, technical, equipment performance (availability, reliability), cost performance (maintenance, labour, and material cost), and progress performance (ratio of planned and unplanned work, schedule compliance). In analyzing key performance indicators (KPIs), Kumar et al. [6] devised a list of maintenance goals, maintenance functions, and associated key performance indicators.

Researchers have developed frameworks and models for industrial applications. Their utilization is organizational based. The following section focuses on the frameworks and models that were developed. A thin line exists between the framework and model as researchers interchange the two [1]. However, we have adopted the terminology used to present them. We followed the term developer of the tool used’.

2.3 Frameworks

Parida et al.[1] identified 27 frameworks based on a literature review. However, some of the identified frameworks measure the overall company performance and lack focus on evaluating the maintenance strategy. For example, Sink and Tuttle’s [32] framework does not include any specific measures related to maintenance such as maintenance costs or downtime. However, maintenance is a critical aspect of many organisations, and it may be challenging to evaluate maintenance performance without including maintenance-specific indicators [21].

Some previously proposed frameworks are based on financial ratios and may not be the best fit for measuring maintenance strategy performance. The Du Pont Pyramid is an example of such a framework [22]. However, this is a setback in the framework because maintenance strategy performance is not solely determined by financial performance, but involves various factors, including operational efficiency, asset reliability, safety, and compliance.

Some frameworks focus solely on evaluating maintenance strategies. This includes the Preventative Maintenance (PM) matrix framework. Although the framework is commonly used for maintenance strategy performance, it focuses on cost factors and does not fully capture broader aspects of performance, such as reliability, safety, and compliance. While cost is an essential factor in maintenance management, it should not be the only metric used to measure the performance. In addition, the PM matrix does not consider the long-term effects of the maintenance strategies. For example, a maintenance strategy that reduces costs in the short term but leads to equipment failures and costly repairs in the long term may not be considered an effective strategy using the PM matrix. It is commonly used for maintenance strategy performance but has some limitations that should be considered when using it as a performance measurement tool. The PM matrix primarily focuses on the cost factors.

The PM matrix does not account for external factors that impact maintenance strategy performance, such as regulation changes, market conditions, or technological advancements. Finally, the PM matrix may oversimplify the complexity of maintenance management because it treats maintenance as a series of discrete tasks rather than a continuous process. However, this may not fully capture the interconnectedness nature of maintenance management.

The PM Questionnaire is widely used to measure the performance of maintenance strategies. However, the framework focuses on preventive maintenance and does not consider other maintenance strategies such as corrective or predictive maintenance. This narrow focus can lead to an incomplete understanding of the overall maintenance performance and may not provide a comprehensive picture of maintenance strategy effectiveness. The complete list of identified frameworks and measures/indicators/criteria is shown in Appendix A.

2.4 Models

Several models have been proposed to measure the maintenance strategy framework performance. The results are summarised in Table 1.

Table 1: Models for measuring maintenance strategy performance

	Categories	Models	Description
Maintenance measurement methods	Economic value	❖ Value-driven maintenance ❖ Life cycle cost analysis (LCC) ❖ Life cycle profit (LCP) ❖ Sustainability statement	The models that fall under this category are of the economical type. The focus is on costs, net present value or profitability
	Categorisation of maintenance losses	❖ Cost of poor maintenance (CoPM) ❖ Cost deployment ❖ Waste reduction (related to maintenance)	The models that fall under this category describe different approaches to map the losses related to maintenance activities. In addition, these models identify maintenance losses in the system.
	Cost and cost-effectiveness	❖ Total quality maintenance (TQMain)	In this category, the focus is on cost-effectiveness on

	associated with maintenance	❖ Model to describe and quantify the impact of vibration-based maintenance. ❖ A computerized model to enhance the cost-effectiveness of production and maintenance dynamic decisions. ❖ Maintenance function deployment (MFD) ❖ CA-Failure ❖ Fuzzy multiple criteria decision-making model ❖ Activity-based costing (ABC) for cost estimation ❖ Cost-effective degradation-based maintenance ❖ Probability distribution of maintenance costs ❖ Cost model for maintenance services	maintenance issues. The models aim to assess the changes suggested in a system.
	Overall management	❖ Total productive maintenance ❖ The Eindhoven University of technology model	The models in this category provide guidelines on how to work with maintenance management. The main objective of these models is to plan and control maintenance activities.
	Function oriented planning	❖ Reliability-centred maintenance (RCM) ❖ Terotechnology model ❖ Kelly's Philosophy ❖ Risk-based maintenance	Models included in this category are related to the function and reliability of the maintenance system. The focus is on evaluating the different types of failures, among other things.
	Maintenance and simulation	❖ Simulation and maintenance	The model focuses on preventive and corrective maintenance and their impact on resource allocation, performance, and costs.

Table 1 highlights the diverse range of models available for measuring maintenance strategy framework performance. The lessons from these models can help organisations optimize their maintenance strategies and improve the efficiency and effectiveness of their maintenance activities. These models can also assist organisations in optimising resource allocation and making informed decisions to achieve better maintenance strategy outcomes.

3 METHODOLOGY

Three electronic databases were used for this study. These are Scopus, Web of Science, and Emerald. In this process, different maintenance performance measurements and management articles were retrieved and analysed. In addition, this study focused on the methods used in maintenance strategy performance measurement. This has resulted in the identification of various maintenance performance measurement issues and challenges.

The search was restricted to peer-reviewed academic journals, conference articles, book sections and which are in Engineering and written in English. Screening of the initial search results was done through the review of the title and abstract. Articles that were not about maintenance performance measurement were discarded. The final review was on reading the full article text, those that did not address the maintenance performance measurement were discarded.

The remainder of this paper is organised as follows. After a brief introduction, a literature review methodology is provided in Section 2. The section discusses the maintenance performance measurement methods. These are the proposed models and frameworks, including the KPIs. Section 3 discusses the methodology while section 4 discusses the gaps in this study. The development of the proposed conceptual framework is discussed in section 5, and section 6 concludes the paper. Section 7 provides future research.

4 GAP

We identified several gaps in the proposed methods for measuring the performance of the maintenance strategies. These include frameworks with a financial focus, approaches for short-term measures, and failure to measure and integrate all the factors critical to the success of the maintenance strategy.

Traditional financial performance measures provide little indication of future performance and encourage short-termism [1], [23]. The proposed methods are internal rather than externally focused, with little regard for competitors or customers [15], [24]; they lack strategic focus and often inhibit innovation. There is little evidence that organizations ensure complete reflection of organizational maintenance strategies, thus implementing new measures to add new priorities.

5 DEVELOPING THE FRAMEWORK

The developed framework is guided by the integration of maintenance results derived from the overall organisational maintenance strategy [25], [26]. This can be realised through an improved understanding of the operation and maintenance process by identifying, developing, and implementing appropriate quantitative and qualitative performance indicators (PIs) for the maintenance strategy performance measurement system [1]. Furthermore, we assume that the maintenance objectives pursued at a given plant influence performance indicators [27].

The developed maintenance strategy performance measurement framework is used to measure different aspects such as maintenance financial reports; customer satisfaction; monitoring the performance of employees; the health, safety, and environmental (HSE) rating; and overall equipment effectiveness, competitor ranking, productivity, and improvement of the organisation [10]. In addition, it also measures the maintenance budget, plant or system availability targets, and between failures and repair (MTBF and MTTR), maintenance reliability, and downtime are examples of KPIs.

Therefore, asset managers need to measure and determine the relationship between the outputs of the maintenance process and their total contribution to the business objectives. In addition, the efficiency and quality of maintenance need to be measured through key performance indicators (KPIs) to justify investment in maintenance [18]. Key performance indicators must be developed and implemented with the total involvement of the entire organisation.

Maintenance strategy performance indicators are linked to reducing downtime, costs, and waste and enhancing capacity utilisation, productivity, quality, health, and safety. The maintenance strategy performance indicators differ for different industries [28]. Maintenance performance indicators can be classified into several categories. One common method is to classify them into two categories: economic and technical indicators [29]. We use several maintenance strategy performance indicators to enable different practitioners to use our framework. However, the maintenance strategy performance indicators in our developed framework are not exhaustive. However, when organisations develop maintenance strategy performance indicators, the number should be kept as low as possible because monitoring and controlling several indicators is impossible[30].

The framework highlights both lagging and leading indicators. Establishing a link between the lagging and leading indicators helps monitor and control the performance of the process, and the indicators to be linked are selected according to the chosen maintenance strategy [1]. The leading indicator is the maintenance process. Maintenance leading indicators monitor whether tasks are performed well to attain the desired production results [27]. The maintenance strategy process is addressed through identifying work, planning, scheduling, executing, completing work and the continuous improvement phase [31]

The lagging factors are the results of the maintenance process [27]. Our framework is based on maintenance financial reports, reduction of downtime and waste, equipment performance, customer satisfaction, breakdown frequency, health, safety, environmental rating, and competitor rating. In addition, we included benchmarking under lagging performance indicators because it is critical for achieving world-class maintenance performance levels [32], [33]. Therefore, benchmarking is a critical element in the continuous improvement process.

The developed maintenance strategy performance framework aligns business and maintenance objectives, operation and maintenance requirements, and provides a link between the maintenance objectives, maintenance process/efforts, and maintenance results [27].

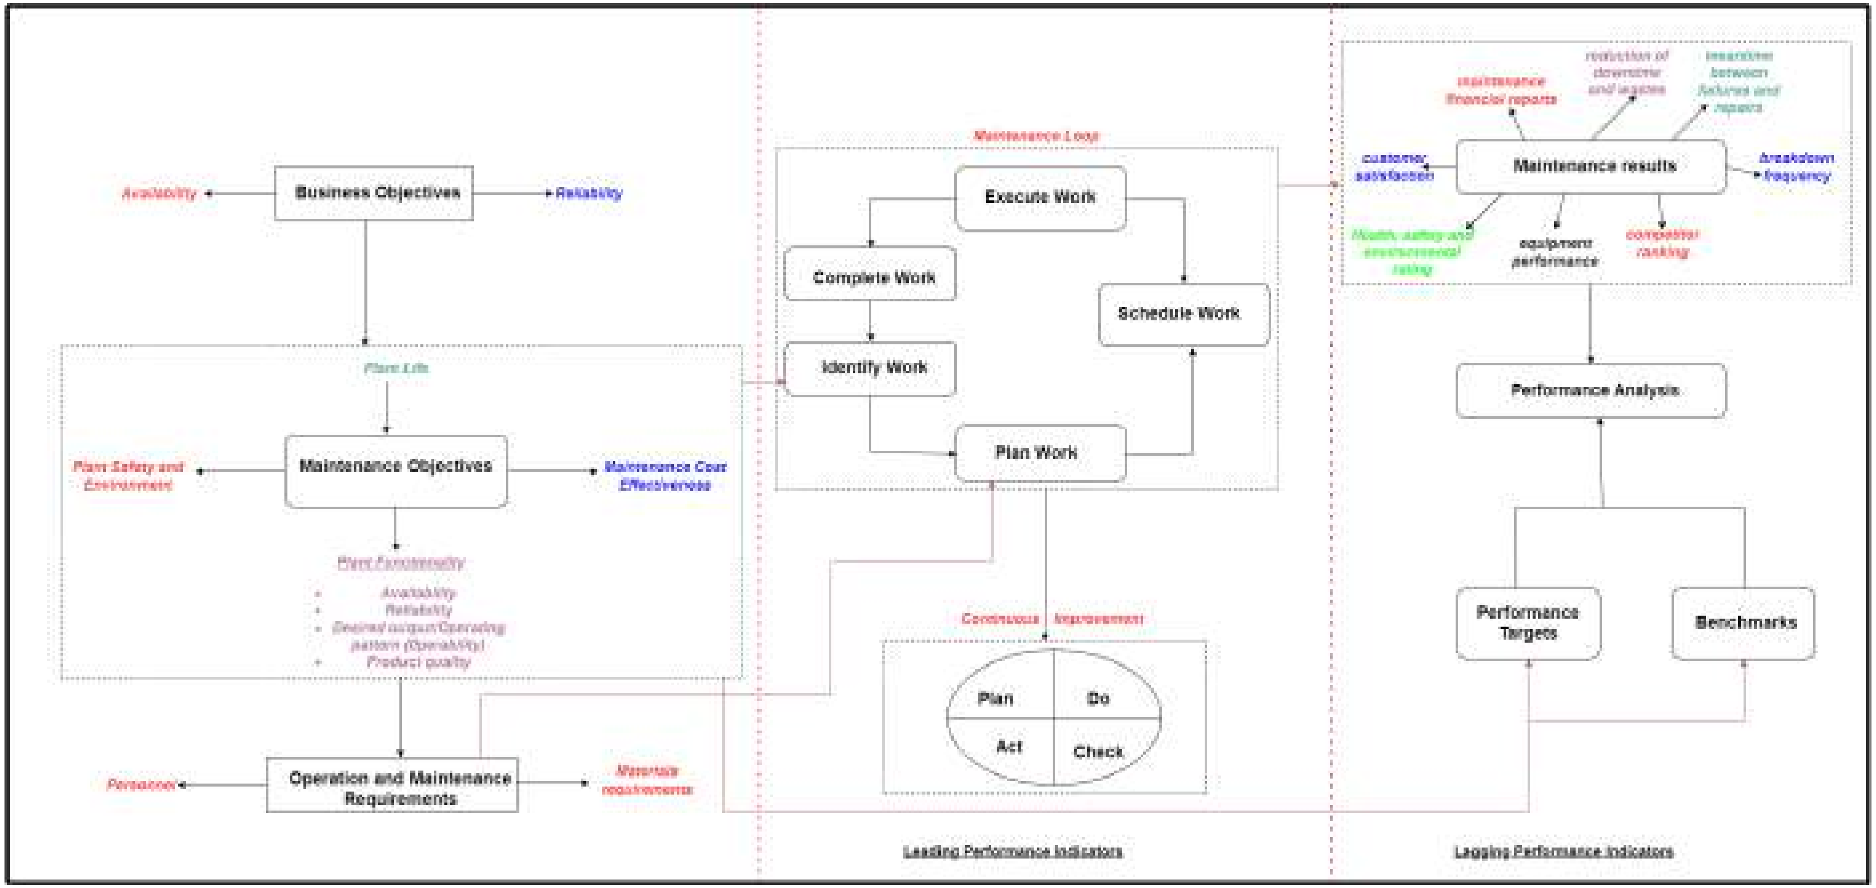

Figure 1 Maintenance strategy performance measurement framework

6 CONCLUSION

An approach (framework) for maintenance strategy performance measurement was developed based on an extensive literature review of different environments. It was developed to make the measurement of maintenance strategy performance feasible. The literature review identified business objectives, maintenance objectives, operation and maintenance requirements, maintenance processes, and maintenance results to formulate a maintenance strategy performance measurement framework. The framework establishes a link between maintenance and business objectives. From the developed framework, business objectives influence the type of maintenance objectives to be implemented. Maintenance objectives enable the organization, in this instance, to meet its business objectives. This study developed a conceptual framework that provides guidelines for choosing maintenance performance indicators by aligning manufacturing and maintenance objectives. The conceptual framework provides a generic approach for developing maintenance performance measures with room for customization to individual company needs. The aim is to ensure that key maintenance processes that may lead to the desired results are carried out and evaluated. This research demonstrates that performance indicators are not defined in isolation but should be the result of a careful analysis of the interaction of the maintenance function with other organizational functions. It seems evident that in the overall interest of the organization, maintenance performance criteria should be balanced with the requirements of the manufacturing objectives.

7 FUTURE RESEARCH

The next step of this research is to validate the framework. This will be conducted through interviews with subject matter experts in the field, such as academics and maintenance practitioners. Second, further research is recommended on the methodological approach of choosing the appropriate maintenance performance indicators among the indicators listed in the literature. Third, research is required to investigate how performance measures can effectively improve performance in practice.

ABSTRACT

It has been revealed that good project management in the early stages of a project provides significant chances for reducing many of the challenges that limit project success. In project management, a clearly defined project scope increases the likelihood that the project will be successfully completed within the given timeframe, budget, and desired quality. The goal of this research is to conduct a systematic literature review relating to the effects of scope definition on infrastructure projects. This paper used the literature review method and reviewed published literature ranging from 2013 to 2023. The literature reveals that, despite the fact that project scope determination is viewed as a critical component in successful project management, research on the subject is scarce. The results of the literature review further point out that defining scope in the planning phase maximizes the probability of project success.

Keywords: infrastructure, project management, project success, scope definition

[*] Corresponding Author

1 INTRODUCTION

Projects can be thought of as the accomplishment of a particular goal and require the use of resources on numerous tasks or activities [1].The effective execution of a project within the baseline time, approved budget, and quality parameters depends on a clearly defined project scope [2]. When crucial and legally binding decisions are made about the project's early phases, this is commonly referred to as the front-end of the project. Front-end planning (FEP) is a critical stage before the project is carried out since it determines the project's scope [3].

The goal of FEP is to define a project in sufficient detail to clarify what needs to be done to satisfy the needs of the recipients of project deliverables [4]. Pre-planned projects with a clear scope are thought to be less prone to experience unforeseen events like scope creep, timetable slippages, cost overruns, and poor deliverables [5]. According to research [6], pre-project planning is key for capital projects and has a positive impact on project success. Higher levels of pre-project planning effort can result in significant cost and schedule savings, according to the results of a recent study. The study specifically characterized 53 capital facility projects into three distinct pre-project planning effort intensities and examined the overall possible cost and schedule performance variations as stipulated below:

- 20% cost reduction achieved through extensive pre-project planning
- schedule savings of 39% with intensive pre-project planning

The study came to the conclusion that a thorough scope definition prior to project execution is essential to project success because of the significant savings linked to better project predictability [7]. One of the important pre-project planning phase sub processes is the creation of the scope definition package[8]. The amount of effort spent during the scope definition phase will have a substantial impact on the project's success during the detailed design, construction, and start-up phases [9].

It has been proven that this endeavour is an efficient strategy for improving the likelihood of project success while significantly decreasing project implementation risks[10]. The project's risks are examined at this crucial stage, where the project's specific execution strategy is also established [11]. Failure of a clearly defined scope causes execution-related scope variations that increase costs and cause schedule delays [12].

Padalkar and Gopinath [13] looking at the development of the various themes in project management research, they found that the scope management theme had the least amount of influence on articles. Kagogo and Steyn [6] who cited that 87 project experts have recognized inadequate scope definition as a key cause of project failure, emphasizes the need of scope definition. Additionally, scope management was noted as one of the key factors contributing to project success in the Pulse of the Profession survey results [14], and scope control begins with scope definition and scope preparedness.

The following is the paper's structure: section 2 covers the objectives; section 2 the research methodology; and the literature review is presented in section 4. The results of the review study are discussed in section 5; section 6 covers the conclusion of the study; and lastly, future research is discussed in section 7.

2 RESEARCH OBJECTIVES

The proposed study's objective was to conduct a review on the existing literature related to the effects of scope definition on infrastructure projects. The goal was to focus on the impact of how defining scope can influence the performance in the literature on infrastructure projects and shortcomings in order to maximize the probability of project success.

3 RESEARCH METHODOLOGY

The systematic review method was used in the study methodology. A detailed analysis of the literature on the topic at hand is the basis of a systematic literature review. A literature review is an important part of any research studies. In order to identify potential research gaps, the pertinent literature is evaluated and examined through literature reviews. The research gaps ought to be of the kind that, if filled, would advance the field of study. As highlighted by [15], [16]a structured review of the literature is conducted by iteratively selecting appropriate search terms, looking for the pertinent material, and performing the analysis at the conclusion. In this paper, the authors adopted a similar review procedure.

To enhance the analysis of the reviewed literature, the process began with the identification of the key ideas that related to the research question. The criteria included a generic review of the area under research, as well as limiting reviewed papers to those in English, and ensuring the relevance of the reviewed articles to the area under study. To obtain relevant information consent with the purpose and direction of the research, a keyword search of online databases was conducted on the following topics: effects of scope definition of infrastructure projects, impact of scope definition of construction projects, effect of scope readiness on construction projects.

Filters based on the PRISMA technique were constructed according to[16] in order to determine the degree of relevance of the articles to the topic under investigation. According to the PRISMA technique divides the article extraction procedure into four stages: (1) identification; (2) selection; (3) eligibility; and (4) inclusion. Keywords and complementary terms were employed in all the database searches during the identification step, and all articles identified were extracted for the second stage (selection). In the second stage, the following filters were used: The article type, peer-reviewed status, and English language. Titles and abstracts were read in the third step (eligibility), and papers with content directly linked to the topic were selected, with all others being discarded.

An initial search using the search string was conducted which yielded 80 articles. The researchers conducted a preliminary assessment based on reading the abstracts of all selected papers in order to concentrate on the most pertinent literature.

Searches were conducted from Google Scholar. The inclusion criteria were papers published from 2013 to 2023. From the pre-selected papers, we decided to focus on contributions that responded to three characteristics: peer-review published papers; articles in international journals; and papers written in English. Furthermore, papers were filtered according to abstract and full paper relevance. In the end, only selected articles that are relevant to the subject of discussion were reviewed. A structured review methodology adopted a four-step process as presented in Figure 1 below.

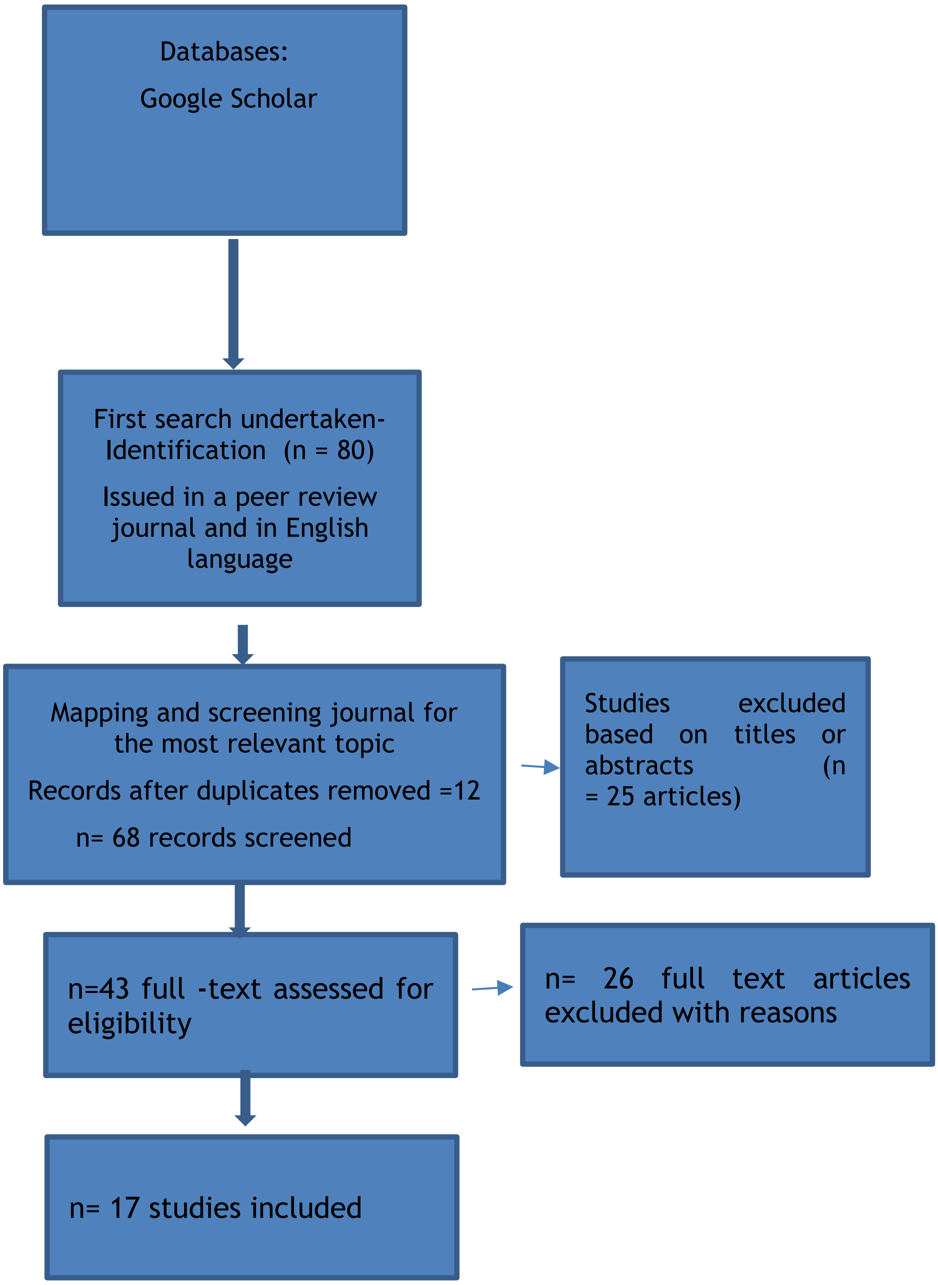

Figure 1: Systematic review flow diagram. Source: Adapted from [15]

3.1 Selection and criteria inclusion of the analysed studies

The research methodology is represented in Figure 1. We used the systematic review principles proposed by [15], [16]. The literature was searched via the search engine of Google Scholar. An iterative process, was used to derive information from the abstracts of published papers. After the first search, a total of 80 studies were identified for our systematic review. To select the final studies to be included in this review, a practical screening was conducted that consisted of the following two steps: 1) the setting of inclusion criteria and 2) the strategy for selecting the potential studies.

3.1.1 Inclusion criteria

To be included in our systematic review, first, a practical screening of the titles and abstracts was conducted following the next inclusion criteria. A study had to meet the following criteria to be included:

- The study must be an article published in a peer review journal in the English language within the last twenty years (2013-2023). Thus, other publication forms (conference proceedings, books, newspaper articles, unpublished works) were not included

3.2 Studies selection

In the second stage, the identified articles were subjected to a double screening. A first sorting of the articles' titles and abstracts allowed us to include 80 potentially relevant studies. Each of these 80 articles were reviewed and assessed according to the inclusion criteria. The second screening went beyond the title and abstract into the full text of the papers. Therefore, after the two-step practical screening, the literature review on finally involves 17 potentially relevant studies that met all the inclusion criteria. All the papers that fulfilled the practical and methodological inclusion criteria were analysed.

4 LITERATURE REVIEW

One of the most important and least understood aspects of management is project management [9]. Construction, defence, power generation, aerospace, product development, software, and other industries are plagued with delays and cost overruns. Projects often appear to be on schedule until near the finish, when faults made earlier are revealed, causing costly rework, expediting, overtime, hiring, schedule slippage, or project scope or quality reductions [17].

4.1 Infrastructure project lifecycle

Implementing phases of the project lifecycle are better for managing infrastructure projects. As illustrated in Figure 2, these projects are normally selected and executed in accordance with four main phases: (1) initiation phase; (2) planning phase; (3) execution phase; and (4) project closure [3].

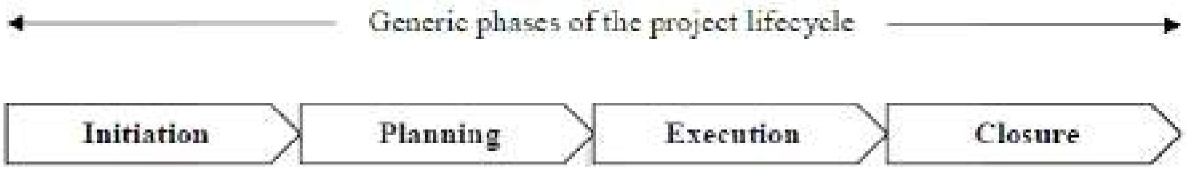

Figure 2: Project lifecycle phases. Source: Adapted from [18]

In the planning stage, a project's requirements and limitations are determined. In the planning stage, a comprehensive project scope is developed, including resource estimation, budgeting, and risk planning [19].

4.2 The project definition rating index (PDRI)

A more recent Construction Industry Institute (CII) study focused on developing an effective technique for measuring the amount of project definition when the project is approved for final funding. The PDRI for Industrial Projects is a new project management tool that helps determine a total score that indicates the degree of scope definition. It is a useful tool that enables a planning team to assess the likelihood of accomplishing project goals during pre-project preparation [17]. The PDRI tool was originally developed for industrial enterprises, including heavy manufacturing, chemical and power plants, and oil refineries [20]. The PDRI for Industrial Projects is a weighted worksheet of 70 scope definition components. The 70 components are broken down into 15 categories and three major divisions. The components were assigned a pre-defined weighting score; the overall score represented the extent of project definition; with a lower score showing better project definition and forecasting the chance of project success [21]. The project team assesses each of the 70 elements' level of definition, and a score is calculated; the lower the score, the more well-defined the project is and the better the chances of predicting the success of the project.

PDRI can be used as:

- a worksheet that the project team can use to decide what procedures to follow in order to define the project scope
- a list of common terms used in scope definitions across the building construction industry
- an industry standard for evaluating the project scope definition package's completeness that would help with risk assessment and forecasting potential for conflict, escalation, etc
- a way to keep track of development at different points during the front-end planning process
- a way to point out areas in a scope definition package that need more clarification, as well as an instrument that promotes communication and alignment between owners and design contractors
- a benchmarking tool for businesses to utilize in comparing the performance of previous projects, both internally and externally, to the completion of scope definition in order to forecast the likelihood of success on future projects

The project's scope management process can be made more effective with the support of the PDRI. When the project scope is established and verified, it is simple to integrate the PDRI into the preliminary planning stage[22]. In particular, the five main pre-project planning sub processes (scope management) can be improved with the PDRI: initiation, scope planning, scope definition, scope verification, and scope change control [6].

- **Initiation:** The PDRI can assist in defining the project's overall requirements for creating and putting together the project team. It can help in comprehending the scope definition's needs and goals by all project stakeholders. The PDRI can also be utilized to establish a baseline for comprehending the building's current state of project definition.
- **Scope planning:** The project team can determine which components of the scope package for the building project are most important using the PDRI. A scope management plan and a scope statement are the end products of scope planning.
- **Scope definition:** In order to measure progress, evaluate risk, and focus future work, the project scope package's completeness can be scored using the PDRI during the planning process.
- **Scope verification:** From the perspective of the project participant, PDRI scores represent the quality and completeness of the project scope package.
- **Scope change control:** The PDRI forces a good, written scope description when utilized correctly.

4.3 Project scope versus product scope

Mirza, Pourzolfaghar and Shahnazari [1] said within the project or program system, the product is a separate system. There are various needs, goals, objectives, stakeholders, drivers, and interfaces for both the project and product scopes. The project scope will have an effect on the product, but other factors will also play a role. The work necessary for creating the project deliverables will be covered by the project scope. The project's scope is defined by the work necessary to accomplish its objectives. On the other hand, a product scope refers to the attributes and characteristics of the outputs of a project [23].

4.4 Project success factors

The guiding concepts that steer the project team's work are scope and objectives. They determine if a project will succeed or fail. One of the most crucial duties in new or development projects is the division of large projects into smaller projects or work packages [18], [24].

Figure 3: Combination of project and product scope influences project success Source: Adapted from [18]

5 RESULTS AND DISCUSSION

Table 1: Studies on effect of scope definition on infrastructure projects

Published	Authors	Title	Purpose	Conclusion
2013	[1]	Significance of scope in project success	Scope is a major contributor in project success.	It is concluded that a greater understanding of the distinction between project and product scope can increase the likelihood of project success.
2013	[9]	Building project scope definition using project definition	The key parts of project scope definition have been highlighted.	Poor scope definition is acknowledged as one of the primary causes of project failure by industry practitioners, influencing projects in terms of cost, schedule, and operational characteristics.
2013	[23]	Managing project scope definition to improve stakeholders' participation and enhance project outcome	The study's goal is to create a technique that will assist a project management team in determining the completeness of project scope specification.	Project definition is improved by managing scope definition and stakeholders.
2014	[25]	Significant Causes and Effects of Variation Orders (VO) in Construction Projects	Hence, the aim of this study is to determine the significant causes and effects of VO in construction projects	The results of the study showed that in Malaysia's projects often have Vo's; majority caused because of, poor workmanship, scope change and design complexity.
2016	[2]	The effect of scope definition on infrastructure projects: A case in	The purpose of this study was to investigate the impact of scope specification on public	According to the findings, there is a considerable direct association between scope

Published	Authors	Title	Purpose	Conclusion
		Malawi's public and private implementing agencies	building projects performed by project implementing agencies (PIAs) in Malawi.	specification and the performance of the sampled infrastructure projects. Projects that were well specified tended to have strong project performance indicators, whereas poorly defined projects tended to have poor project performance indicators.
2016	[26]	Causes and Effects of Scope Creep on Large-Scale Public Sector Construction Projects	The study identifies, explores and models the causes and effects of scope creep of large-scale public-sector construction projects in the Southeast Geopolitical Zone of Nigeria .	The result of the analysis indicates that lack of knowledge and poor understanding of products versatility, and complexity as the most significant cause of scope creep of construction projects with resultant adverse effects on both the projects and the managers
2017	[27]	Key activities in defining the scope for infrastructure projects	To investigate whether applying best practices to the project scoping process could have a positive impact and eventually improve the performance of the infrastructure project.	Defining a clear scope for infrastructure projects and increasing the overall success of infrastructure projects.
2017	[12]	Identifying and managing drift-changes	Project management of unexpected events by investigating a phenomenon known as drift-changes.	Drift-changes occur when external influences have an impact on a project, causing it to generate results that were not initially sought or anticipated by stakeholders.
2018	[28]	Scope creep in construction industry of Saudi Arabia	The impact of scope creep in construction industry of Saudi Arabia	Scope creep increases the duration of project
2019	[6]	Effect of scope readiness on capital projects in mining: a Namibian case study	The impact of scope readiness on mining capital projects.	Scope readiness definition improves project performance.
2019	[4]	The front-end of projects: a systematic literature review and structuring	A systematic literature review on front-end of projects.	Front-end planning is where scope must be defined to ensure project success.
2020	[29]	The impact of scope creep on project success: an empirical investigation	Identify scope creep factors and provide a conceptual framework for experimentally assessing the influence of scope creep on software project success.	The study's findings assist practitioners in understanding the dynamics of elements that inhibit scope creep in order to boost project success rates.
2021	[18]	Predefined project scope changes and its causes for project success	This paper aims to predefine the potential scope changes to keep the project scope on track and identify any weakness in scope definition at the early stages of a project.	Enhancing project scope quality has a massive impact on the success of a project and it adds more control over project scope.
2022	[24]	What is project success: a literature review guru	Factors that determine project success.	Neither practitioners nor academics appear to agree on the definition of project success. It appears to be a

Published	Authors	Title	Purpose	Conclusion
				difficult notion to grasp. This document seeks to present the perspectives of several researchers in this topic.
2022	[30]	Project scope management and successful implementation of infrastructural health program in Nairobi Country	The study was based on stakeholder's theory, the pure theory of public expenditure, theory of constraints, and theory of change which provided a theoretical framework upon which project scope management implementation can be understood.	The findings revealed that scope management has a positive and significant influence on the successful implementation of infrastructural health program. From the study findings, it was concluded that an increase in scope planning, scope scheduling and scope control would lead to an increase in the successful implementation of infrastructural health program
2022	[31]	Project Scope definition and performance of government construction projects in Kenya	The purpose of this study was to examine the relationship between scope definition and performance of government construction projects in Kenya.	The study found that scope definition had a positive and significant effect on project performance
2023	[32]	Project scope management and successful implementation of projects in non-government organizations in Nairobi	This study sought to establish the influence of project scope management on successful implementation of projects in non-governmental organization in Nairobi	The study concludes that scope definition has a positive and significant effect on successful implementation of projects in non-governmental organization in Nairobi

The researchers reported their findings related to effects of scope definition in infrastructure projects. The findings of the literature research indicate that there is a growing body of knowledge about scope definition. Below are the studies done. To some point, these studies make an attempt to understand the importance of scope definition, which happens during the front-end planning of the project and maximizes the probability of project success. Though even these efforts, little or no research has been done on understanding factors that influence insufficient scope definition and comprehensive project pre-planning regarding infrastructure projects, both external and internal factors, and the impact it has.

5.1 Distribution of articles based on year of publication

The number of scope definition-associated articles published from 2013 to 2023 is presented in Figure 4. In 2013 and 2022 a high number of articles related to this study was published compared to other years. This trend indicates the increasing amount of attention by researchers to improve project performance in infrastructure projects. Interestingly, a slow growth trend occurred in 2014,2018,2020,2021 and 2023, where an average of one article was published annually. In 2016,2017 and 2019, the interest in scope definition was increasing considering the number of articles published.

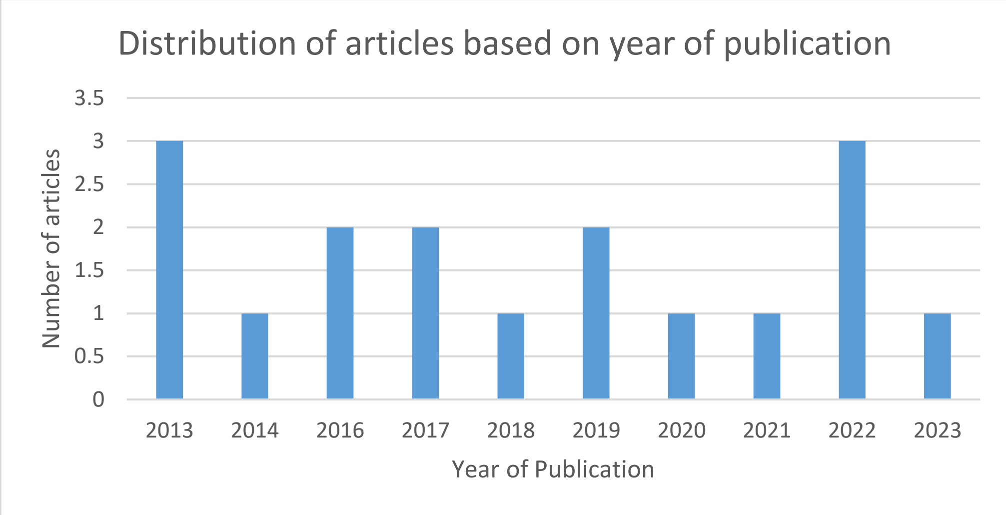

Figure 1: Articles based on year of publication

5.2 Distribution of articles based on journal name

The International Journal of Project Management has the highest number of publications as indicated in Figure 5, with four papers, followed by the South African Journal of Industrial Engineering with three articles, while Procedia Technology, Journal of Architectural Engineering, Institute of Electrical and Electronics, International Journal of Business Management and Procedia - social and behavioural sciences published one article each on the subject. This indicates that the topic of scope definition is covered across different journals with a widespread readership.

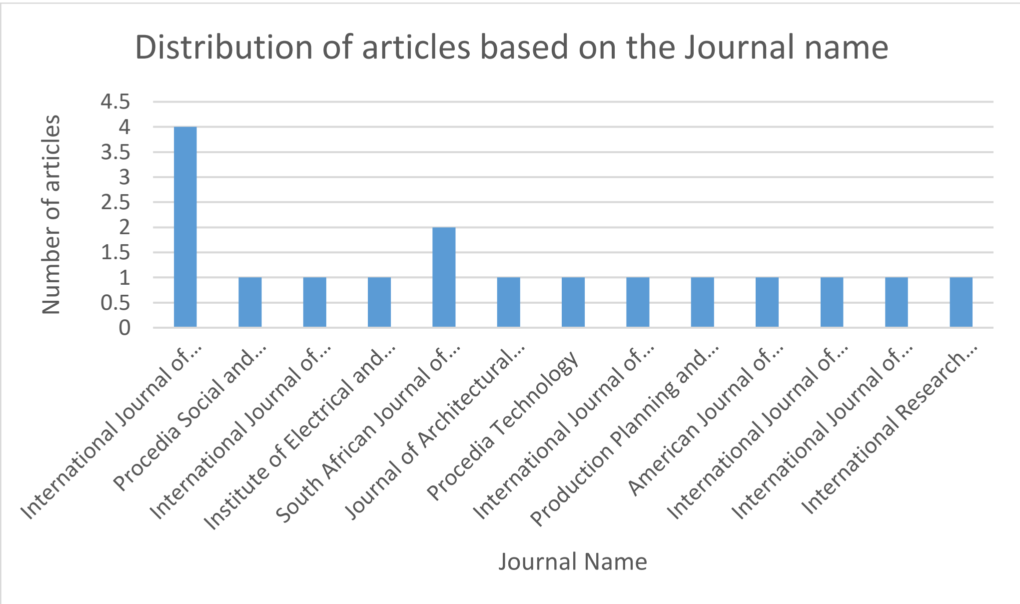

Figure 2: Distribution of articles based on journal name

6 CONCLUSION

The research undertaken identified literature related to scope definition and gaps in the literature. The literature reveals that although project scope definition is regarded as a vital element in successful project management, research on the subject is scarce if looking at the articles tabulated in table 1. The results of the literature review further point out that defining scope in the planning phase maximizes the probability of project success. More research must be done on this topic as it will assist infrastructure projects with better planning, and it will improve the performance of projects. The study's key problem was the scarcity of literature on project pre-planning and scope definition in infrastructure projects. As a result, this study provides a foundation for future research on infrastructure project pre-planning and scope definition.

7 FUTURE RESEARCH

This study suggests further research into the factors that influence insufficient scope definition and comprehensive project pre-planning in infrastructure projects. The implications of additional contingencies on potential poor planning in project life cycle phases should also be considered. There is a good chance that both internal and external forces will affect this occurrence.

ABSTRACT

The Circular Economy (CE) is an economic concept that seeks to promote sustainability and reduce waste by closing the loop of resource use; correspondingly, behavioural system dynamics combines systems thinking and behavioural sciences to analyse complex social systems such as the CE. This paper presents how a qualitative research approach such as grounded theory can validate a behavioural system dynamic model. In the context of evaluating causality between variables in a causal loop diagram, grounded theory is used to validate causes and effects. This involves the systematic analysis of existing literature to identify the relationships between variables in the causal loop diagram. This paper aims to identify the causal relationships between variables and to evaluate the strength of the causal effect. This approach can provide valuable insights into the relationships between CE variables and can inform decision-making in various fields.

Keywords: decision-making, circular economy, systems engineering, dynamic modelling

1 INTRODUCTION:

1.1 Background of the study

The Circular Economy (CE) is a model that presents a framework to further sustainability and moderate waste by managing resource and material uses [1]. It is a complex social system that requires a comprehensive understanding of its dynamics to implement strategies and policies effectively. Behavioural system dynamics combines systems thinking and behavioural sciences to analyse and model such complex social systems [2]. This paper proposes using a qualitative research approach, specifically grounded theory, to validate a behavioural system dynamic model of the CE.

Grounded theory is a well-established research method that involves the systematic analysis of existing literature to identify and validate the relationships between variables also in a causal loop diagram (CLD) [3]. By using grounded theory, the authors can evaluate the causality between the variables and validate causes and effects in the context of the CLD. This approach is particularly useful in identifying the direction and strength of their causal effect within the CE.

This research aims to provide valuable insights into the relationships between behavioural variables in the CE by employing grounded theory to validate the behavioural system dynamic model. These insights can inform decision-making processes in various fields, including policy development, business strategies, and sustainability initiatives. By understanding the causal relationships and dynamics within the CE, stakeholders can identify leverage points for intervention and develop effective strategies to promote sustainability and reduce waste.

1.2 Purpose of the study

By examining existing literature and analysing the relationships between variables in a behavioural CE-CLD, this research aims to validate causes and effects and evaluate the strength of the causal effect. The findings of this study may provide valuable insights into the complex social dynamics of the CE.

This knowledge can guide the development and implementation of effective strategies and policies to promote sustainability and waste reduction [4]. Furthermore, the insights from this study can contribute to the existing body of knowledge on behavioural system dynamics and its application in analysing complex social systems such as the CE [5].

1.3 Significance of the study

The significance of conducting a study on the causal relationships within the CE using a qualitative research approach like grounded theory lies in its potential contributions and implications:

Firstly there is an improved understanding of complex dynamics. The CE is a complex social system with numerous interrelated variables. Investigating and identifying the causal relationships between these variables can lead to a deeper understanding of the dynamics at play.

Also, for more informed decision-making, by uncovering causal relationships and evaluating the direction and strength of the causal effects, this study can provide valuable insights into decision-making processes. Policymakers can utilise the findings to shape policies and regulations that support the transition to a CE. Sustainability practitioners can use the study's outcomes to inform their initiatives and interventions, ultimately driving positive environmental and social impacts. Decision-making in the Circular Economy is currently a focus point for some researchers such as Brenes-Peralta, et al. [6] and Bacher, et al. [7].

Lastly, the advancement of research and theory. This study contributes to the existing body of knowledge on behavioural system dynamics and its application in analysing complex social systems like the CE. It showcases the use of grounded theory as a qualitative research approach to validate behavioural system dynamic models. By expanding the understanding of the CE's causal relationships, this research can inspire further studies and theories in the field, promoting continuous learning and improvement in sustainable practices.

Overall, this study's significance for this paper lies in its potential to inform decision-making, improve understanding, and advance research in the pursuit of a more sustainable and practical CE.

2 LITERATURE REVIEW

2.1 Circular economy and its principles

The CE is an economic model that aims to decouple economic growth from resource consumption and environmental degradation [8]. Unlike the traditional linear economy, which follows a "take-make-dispose" approach, the CE seeks to create a closed-loop system where materials and resources are continuously reused, recycled, or regenerated [9]. This shift towards circularity can help address pressing environmental challenges, promote sustainable development, and unlock economic opportunities. Figure 1 shows the CE framework, with the biosphere on the left and the technosphere on the right.

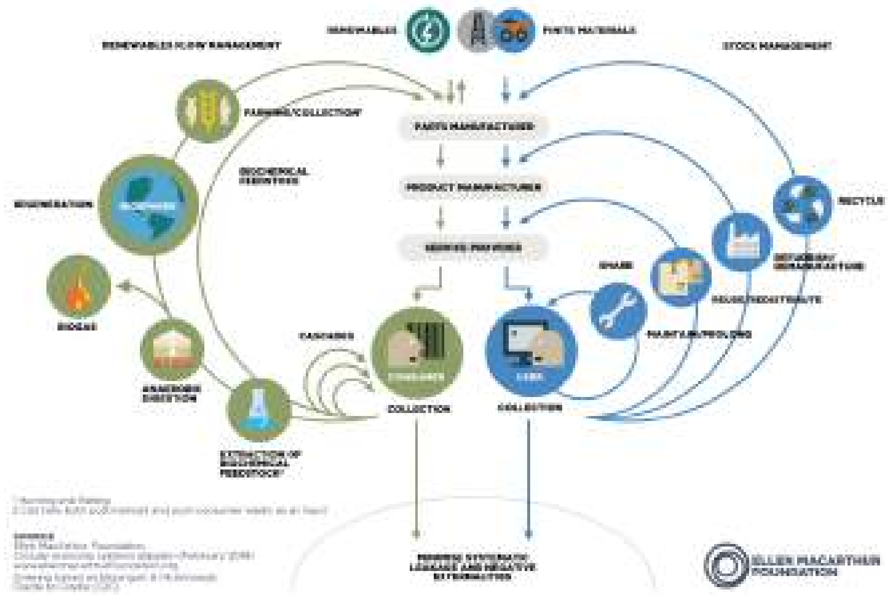

Figure 1: Circular economy butterfly diagram [10]

The principles of the CE can vary somewhat across different frameworks and publications, but they generally revolve around the following concepts:

- A design for circularity. The CE emphasises the importance of designing products and systems with circularity in mind. This principle encourages eco-design, focusing on durability, modularity, recyclability, and using renewable or bio-based materials. Designing for circularity can minimise waste generation, enable easier disassembly, and facilitate resource recovery [11].
- The regeneration of natural systems. This principle highlights the need to restore and regenerate natural systems and resources. It involves practices such as regenerative agriculture, reforestation, and sustainable land management to ensure the

preservation of ecosystems, biodiversity, and soil fertility. By safeguarding natural resources, the CE aims to maintain their availability for future generations [12].

- Preserve and extend the product lifespan. Extending the lifespan of products is crucial to the CE. This principle encourages repairing, maintaining, and upgrading goods to prolong their use. It also promotes sharing and access-based models, such as product leasing, rental services, and the sharing economy, to maximise the utilisation of products and minimise waste [13].
- Shift to renewable energy. The transition to renewable energy sources is a key principle of the CE. By replacing fossil fuels with renewable energy options like solar, wind, and hydropower, the CE aims to reduce greenhouse gas emissions and mitigate climate change. This principle emphasises the importance of energy efficiency and the adoption of clean energy technologies [14].
- Close material loops. Most importantly, closing material loops are central to the CE concept. It involves recycling and recovering materials at the end of their product life cycle. This principle promotes waste separation, sorting, and recycling infrastructure, as well as the use of innovative technologies to extract value from waste and reintegrate materials back into the production cycle [15].

These principles collectively contribute to the goals of resource efficiency, waste reduction, carbon neutrality, and sustainable economic growth within the CE.

2.2 Behavioural system dynamics and its application in the circular economy

Behavioural system dynamics offers a holistic approach to understanding the dynamics and interactions between human behaviour and the circular economy system.

A previous research article examines the suitability of system dynamics modelling in assessing the long-term behaviour and effects of circular business models through a specific case study. The study focuses on modelling and simulating the dynamics of a closed-sharing platform for healthcare institutions, specifically regarding the sharing of durables and consumables. The findings reveal significant potential impacts for durable products, which are influenced by product lifecycle time and the number of use cycles. By utilising system dynamics, this study enables experimentation with CE models by connecting sharing dynamics to resource utilisation and its consequences [16].

Another study focuses on the role of behavioural system dynamics in understanding and promoting circular business models. It demonstrates how the integration of behavioural insights into system dynamics models can facilitate the identification of barriers and drivers for circular business adoption. The research emphasises the need to account for human decision-making, organisational behaviour, and stakeholder interactions when designing circular strategies and interventions [17].

These studies as examples demonstrate the value of integrating behavioural system dynamics into the CE context. Researchers and practitioners can develop more comprehensive and effective strategies for promoting circular practices, influencing decision-making, and fostering sustainable behaviours within the CE by considering human behaviour and social dynamics. In section 3.2.1 a conceptual framework is shown to enable the aforementioned with integrating behavioural system dynamics into the CE context.

2.3 Grounded theory and its role in validating behavioural system dynamic models

Grounded theory is a qualitative research approach that plays a significant role in validating models. It provides a rigorous methodology for exploring and understanding the complex dynamics and relationships within a system, such as the CE.

Research exists that illustrates the application of grounded theory in validating behavioural system dynamic models. The study focuses on developing and validating a system dynamics model of sustainable tourism destinations. Grounded theory is used to analyse and synthesise existing literature, identify causal relationships, and validate the relationships within the model. The findings demonstrate how grounded theory can enhance the validity and reliability of behavioural system dynamic models by ensuring that the model accurately represents the empirical evidence [18].

Bastan *et al.* [19] emphasises the role of grounded theory in validating behavioural system dynamic models through the systematic analysis of literature. The research demonstrates how grounded theory can help identify and validate causal relationships and feedback loops within the model. The iterative process of theory development and testing ensures that the model represents the complex dynamics of the system accurately.

These studies highlight the significance of grounded theory in validating behavioural system dynamic models and can be used as background to develop models for the current research.

2.4 Previous studies on causal relationships between circular economy variables

Research by Geissdoerfer, et al. [1] investigates the causal relationships between various CE variables. The study utilises system dynamics modelling to analyse the interdependencies and feedback loops between variables such as resource efficiency, product design, and waste management. The findings highlight the causal relationships and leverage points within the CE system, shedding light on the factors that can drive or hinder the transition to a CE. These leverage have been included in the conceptual framework in Section 3.2.1.

Furthermore, a study by D'Amato, et al. [20] focuses on the causal relationships between circular business models and sustainability outcomes. The research employs a mixed-methods approach, combining quantitative analysis and interviews, to investigate the impact of circular business models on environmental and economic performance. The findings reveal causal relationships between circular strategies, such as product life extension and resource recovery, and positive sustainability outcomes. These findings show that the strategies followed to influence the succesful implemetation of the CE.

These studies provide insights into the causal relationships between various variables within the CE. By employing different research methodologies and focusing on specific aspects of the CE, they contribute to the understanding of how different variables influence the transition to a circular economy. The studies also show that a gap exists to include the human decision-making factors such as biases for example.

3 METHODOLOGY

3.1 Research design and approach

The research design for this paper follows a qualitative approach, specifically utilising grounded theory methodology. In this study, the research design systematically analyses existing literature to identify and validate causal relationships between variables in a behavioural system dynamic model of the CE. The iterative nature of grounded theory allows for the refinement and validation of the model based on empirical evidence, which will be addressed in future research [21].

The approach begins with an extensive literature review of relevant studies, reports, and scholarly articles related to CE and behavioural system dynamics. The review aims to identify key variables, theoretical frameworks, and empirical evidence on the causal relationships between these variables. A preliminary causal loop diagram serves as the foundation for identifying these variables.

Next, the grounded theory approach systematically analyses the literature to identify patterns, themes, and relationships between the variables [22]. This analysis includes coding and categorising the data, looking for commonalities and divergences, and identifying the direction and strength of the causal effects. The process of constant comparison and theoretical sampling is employed to refine the causal loop diagram and validate the relationships between variables based on empirical evidence.

The research design also incorporates the use of theoretical sampling, where additional literature is selected strategically to fill gaps and explore specific aspects of the causal relationships. The iterative process of data collection, analysis, and theory development continues until saturation is reached, meaning that no new information or relationships emerge from the data [23].

Overall, the research design and approach for this study combine a rigorous analysis of existing literature through grounded theory methodology to identify, validate, and refine the causal relationships between variables in the behavioural system dynamic model of the CE. This approach ensures the integration of empirical evidence, providing a solid foundation for understanding the complex dynamics of the CE and informing decision-making in various fields.

3.2 Data collection and analysis

3.2.1 Data Collection:

The data collection process aims to gather empirical evidence and theoretical frameworks related to the causal relationships between the variables in the CE. The inclusion criteria for the literature will be based on the relevance to the research topic and the quality of the source.The authors looked for scientific behavioural system dynamics and CE-related papers in the Scopus database. Although other databases such as Web of Science (WoS), IEEE Xplore, ScienceDirect and Google Scholar can be included, studies have confirmed Scopus as a good academic database for bibliometric analysis studies [24-26].

The main keywords for the literature search were selected from a previously constructed CLD, as shown in Figure 2. Literature papers between 2005 and 2023 were chosen for the analysis, due to the emergence of significant developments in the field of CE around that time and the availability of a substantial volume of relevant literature. Lastly, the authors centred our focus on journals with high-impact factors according to the CiteScore on Scopus.

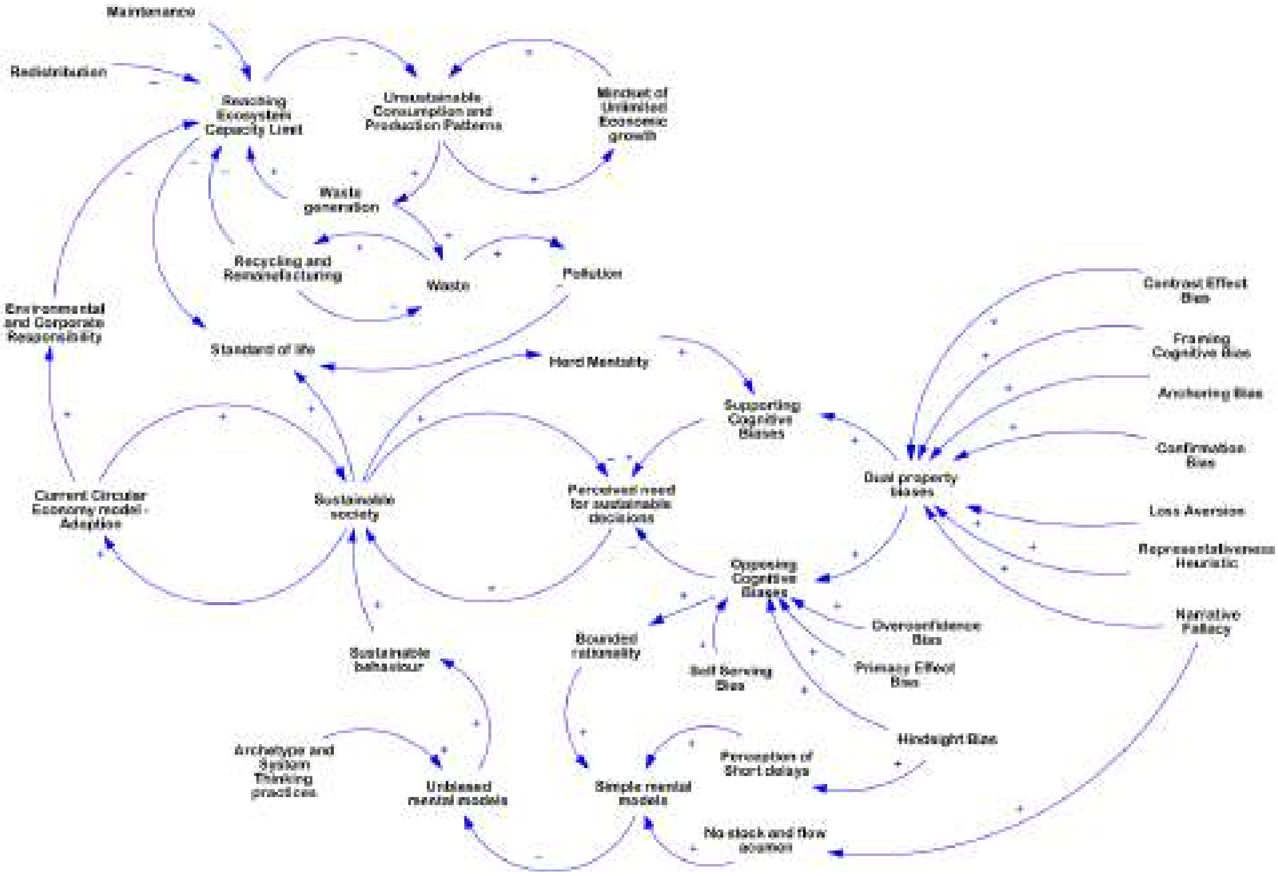

Figure 2: Conceptual integration of cognitive biases in the CE phases

The literature search resulted in a total of 186 papers. The most recent paper was published in March 2023, the same month when the literature retrieval stage was concluded. Figure 3 explains the literature search and retrieval process used. This systematic review methodology excluded any influential books because books are frequently categorised as grey literature possibly owing to the absence of a rigorous peer-review process, in certain instances [27].

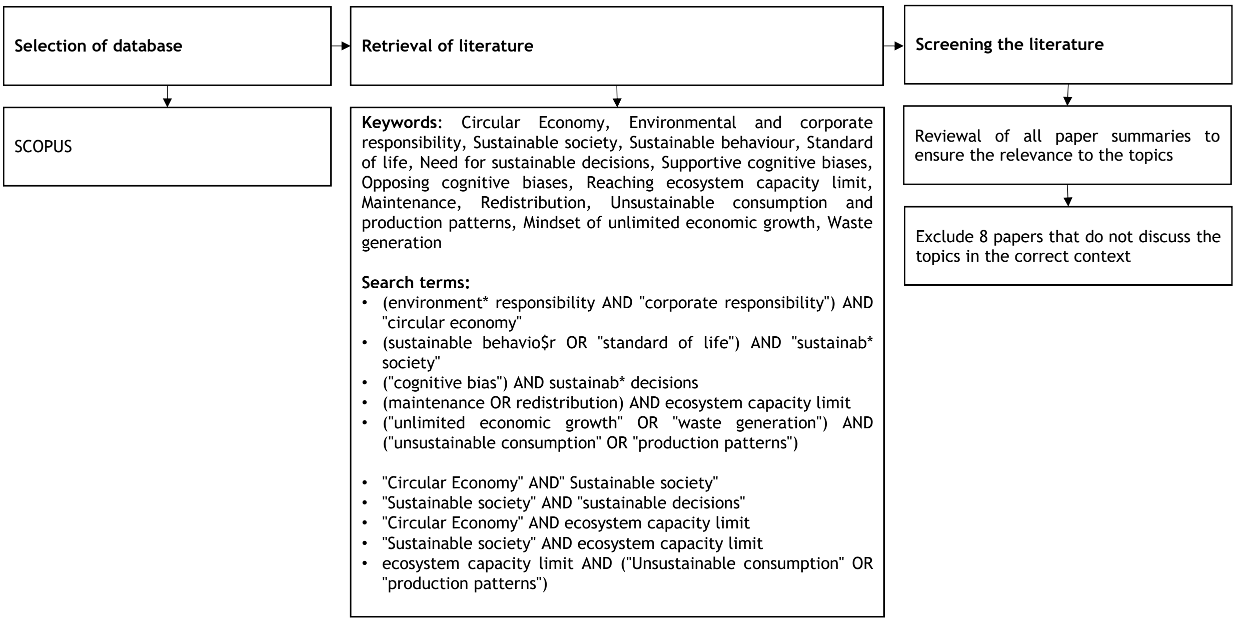

Figure 3: Literature retrieval and screening process

3.2.2 Data Analysis:

The data analysis begins with open coding, where the collected literature is thoroughly reviewed and coded to identify patterns, themes, and relationships between variables [21]. The coding process involves line-by-line coding, assigning codes to paragraphs representing specific concepts or relationships. Through constant comparison, codes are grouped into categories, allowing for the identification of recurring themes and concepts.

After the initial coding process, focused coding is conducted to refine further and consolidate the identified categories and subcategories. This involves selectively coding the most relevant data to the theoretical framework. This involves systematically analyzing the collected information to extract key insights and patterns that contribute to a deeper understanding of the framework. The focused coding process allows for identifying core categories and developing a conceptual framework that represents the causal relationships between variables in the CE.

The analysis process also involves constant comparison of the identified categories and relationships to refine and validate the emerging theory. The resulting codes and code groups for this research are shown in Figure 4 below.

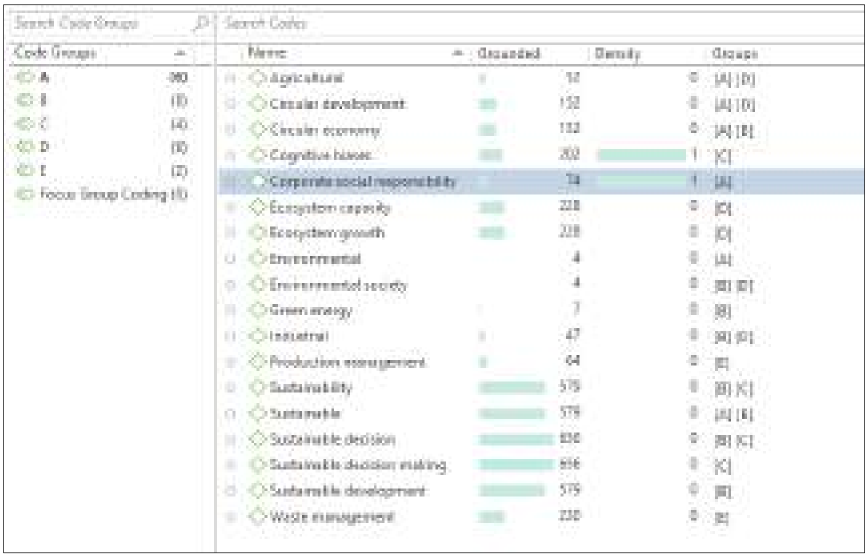

Figure 4: Code manager for the study

The data analysis is supported by qualitative data analysis software such as Atlas.ti to manage the coding process, organise the data, and facilitate the identification of patterns and relationships within the collected literature.

3.2.3 Saturation Test

The authors decided to do a saturation test that involved randomly reserving ten journal papers before coding the remaining papers and then recoding the reserved papers with the rest. After this step, all the existing codes and categories coincided identically. No new codes or themes related to the paper's topic appeared, meaning theoretical saturation had been achieved [28].

Overall, this study's data collection and analysis involved a rigorous and iterative literature review process, coding, and theoretical sampling, following grounded theory methodology. This approach ensures the systematic identification, refinement, and validation of the causal relationships between variables in the behavioural system dynamic model of the CE.

In summary, the saturation test involved a systematic process of coding both a subset of reserved papers and the rest of the dataset, followed by a comparison to ensure consistency.

3.3 Validating causal loop diagram through grounded theory

3.3.1 Grounded theory

The process steps followed to validate the CLD are shown in Figure 5. By following these steps, the researchers can validate the causal loop diagram and gain insights into the causal relationships between variables in the circular economy.

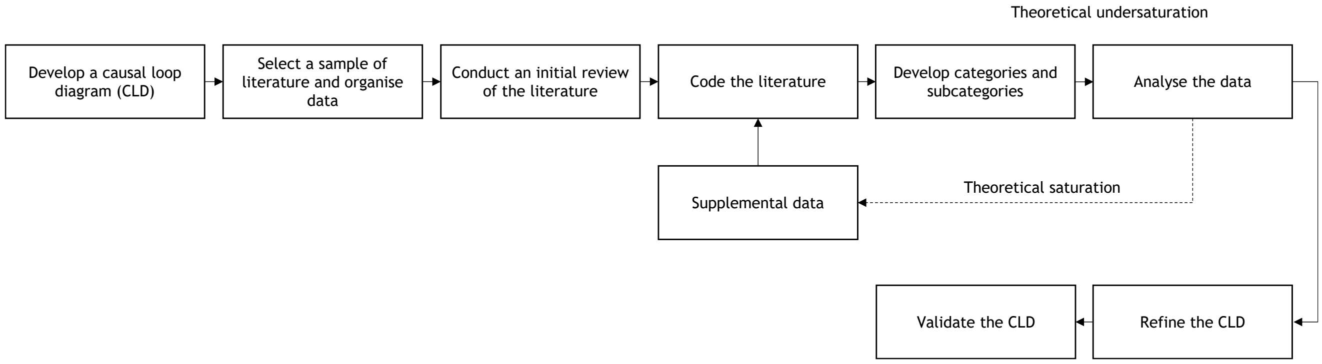

Figure 5: Grounded theory sequence as applied in this paper

The patterns and relationships are analysed to validate the CLD with the coded literature. The codes and CLD variables are reviewed and presented in a network in [6] to reveal any new relationships between variables or suggest changes to existing relationships in the CLD.

The CLD is refined based on the findings of the data analysis and validated by using the results of the grounded theory analysis. This involves assessing whether the causal relationships in the CLD are supported by the literature and the data analysis. In Figure 5 these steps are visualised in sequence. The following section presents the final version of the CLD after 2 iterations of coding and building the networks.

4 RESULTS AND DISCUSSION

4.1 Identification of causal relationships between circular economy variables

To highlight the interconnected nature of CE variables and demonstrate how changes in one aspect can influence and drive changes in others, fostering a more sustainable and circular economic system, the coded variables from the literature were applied to the CLD. For example in Figure 2 the sustainable society is influenced positively as the rate of adopting a CE increases and the negative is also true. The more sustainable the society gets, the perceived need for making sustainable decisions decreases.

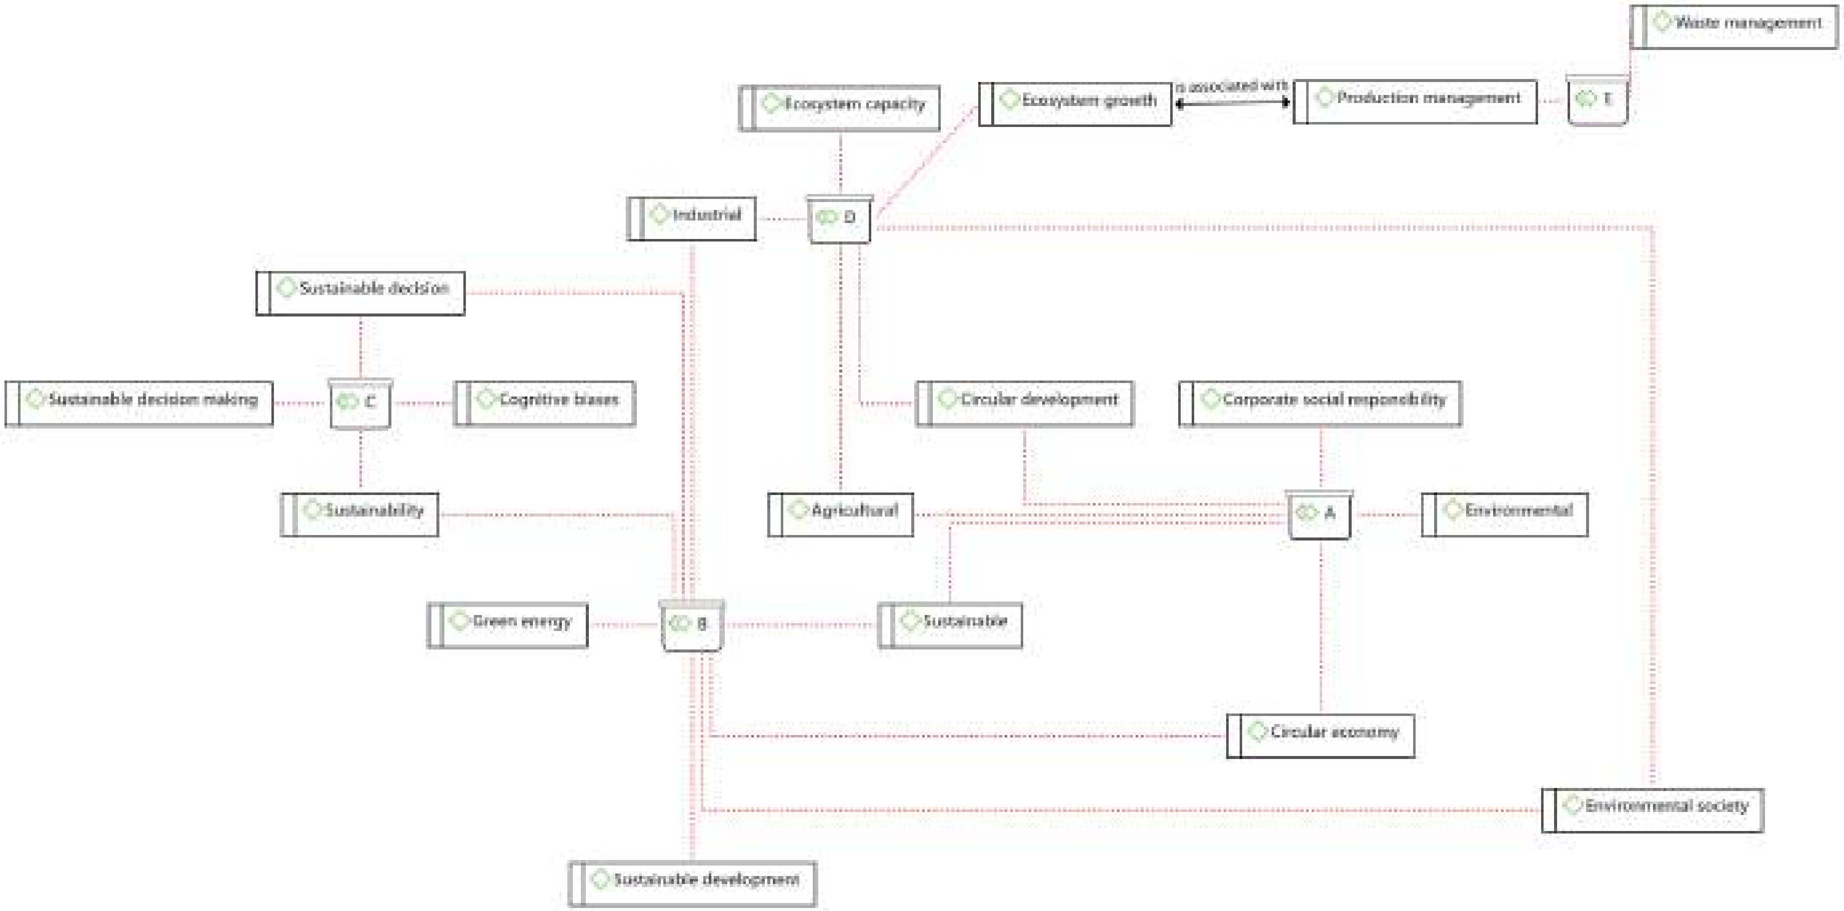

Figure 6: Code network with CLD

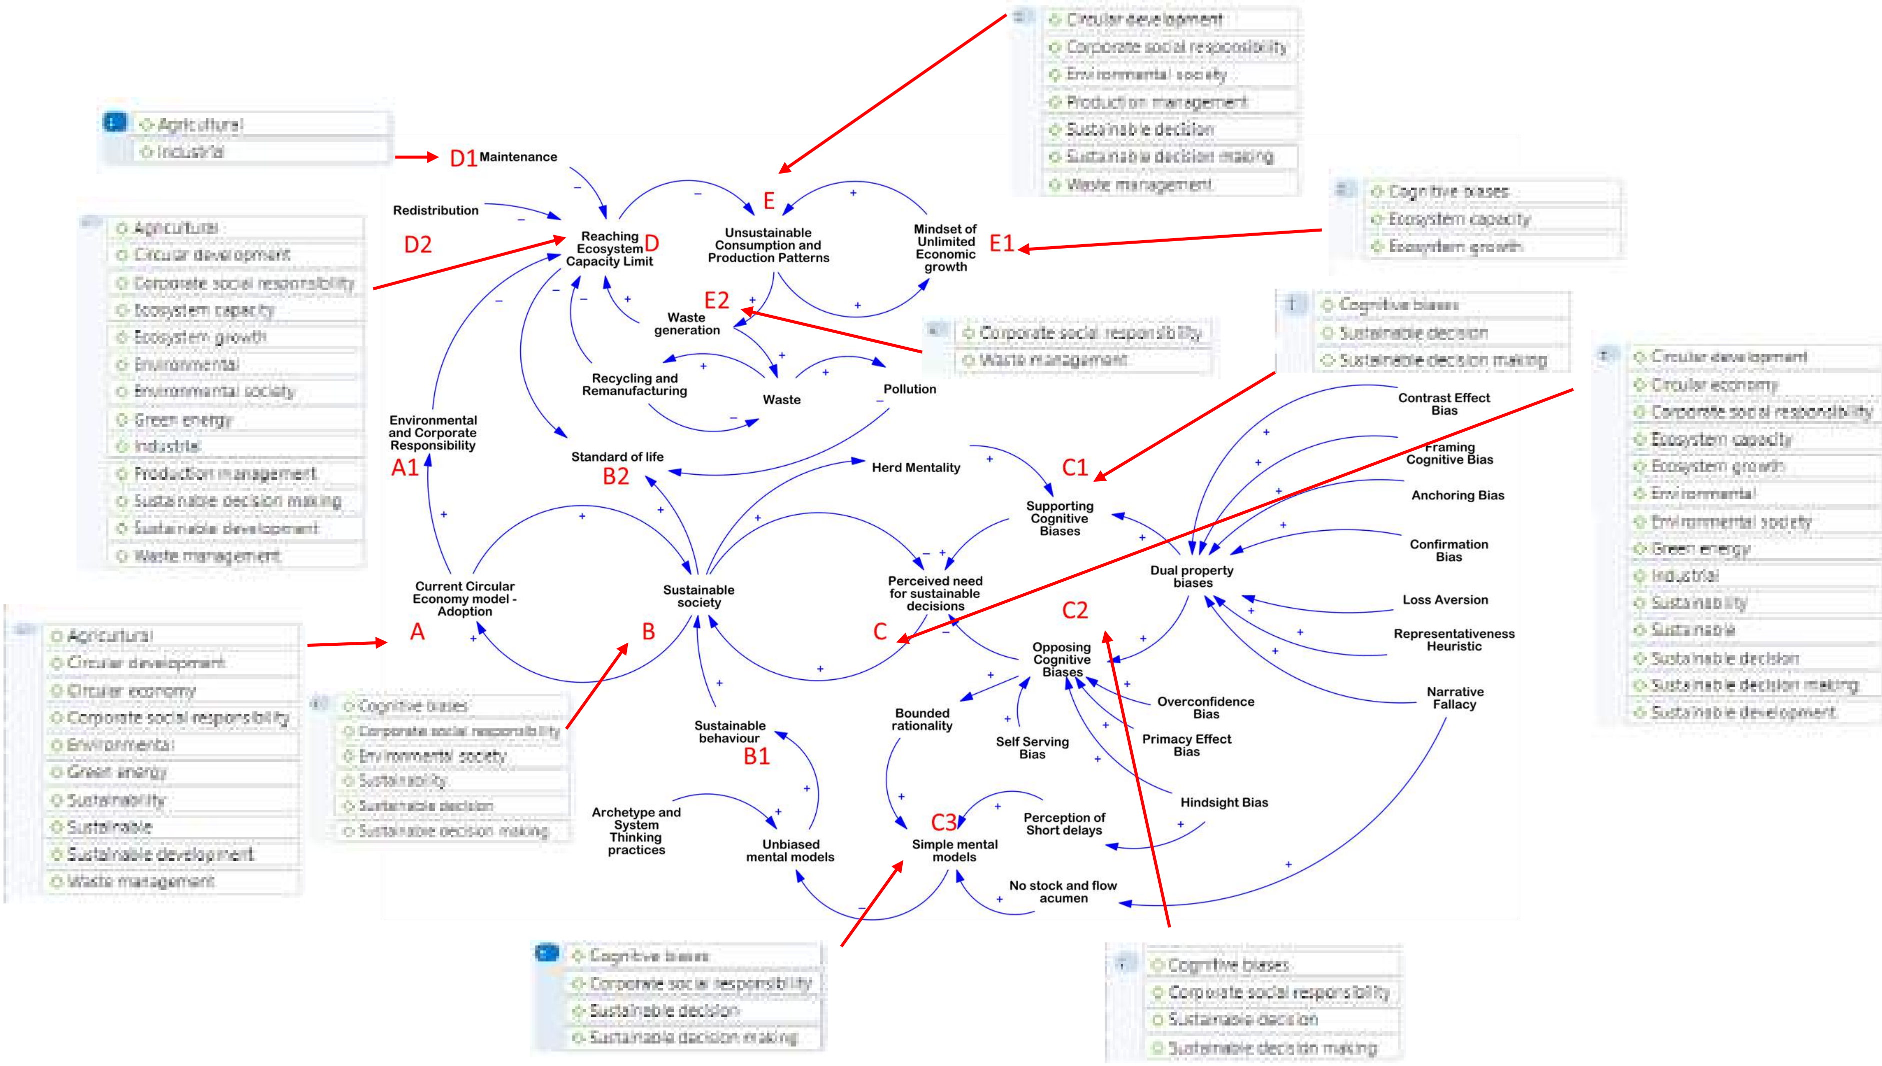

Figure 7: Variable coding added to the CLD

Figure 7 represents how sustainable decision-making can drive the adoption of CE practices, which in turn can enhance waste management and production management strategies. Additionally, the availability and utilisation of green energy sources can contribute to both environmental sustainability and sustainable development. Corporate social responsibility (CSR) influences sustainable decision-making within organisations. A strong commitment to CSR can lead to more environmentally conscious and socially responsible business practices, including adopting circular economy principles. Effective waste management practices positively impact production management. By implementing efficient waste reduction, recycling, and resource recovery strategies, businesses can optimise their production processes, reduce material waste, and enhance overall resource efficiency, which is the aim of the CE all together.

Cognitive biases can hinder the adoption of CE practices. Biases like status quo bias or risk aversion may discourage individuals and organisations from embracing innovative circular business models or making sustainable decisions that involve initial investments or changes to established routines. Consider a manufacturing company that has been using a traditional linear production model for years. Despite the potential benefits of transitioning to a circular economy approach, the management team might be influenced by the status quo bias. This bias could lead them to resist change and stick to familiar practices, even if circular models offer long-term advantages. Ecosystem growth and capacity impact agricultural practices. Sustainable agricultural techniques, such as agroecology or organic farming, can enhance ecosystem health, biodiversity, and soil fertility, leading to more resilient and sustainable food production systems.

Circular development approaches can contribute to the formation of environmental societies. By integrating CE principles into urban planning, waste management, and resource allocation, communities can create sustainable living environments that promote environmental awareness, resource conservation, and a culture of sustainability. Identifying causal relationships is crucial for developing comprehensive strategies and policies that promote a more circular and sustainable economic system.

4.2 Evaluation of the strength of the causal effect

The direction and strength of the causal effects between the mentioned CE variables can vary depending on the specific context and circumstances. In some cases, the causal relationships may exhibit strong positive effects, indicating a direct and significant influence from one variable to another. For example, strong corporate social responsibility practices within an organisation can lead to more sustainable decision-making and greater adoption of circular economy principles. Similarly, effective waste management strategies can directly improve production management efficiency. However, it is essential to note that external factors and complexities within the system can also influence causal effects. Some relationships may be more nuanced, exhibiting indirect or moderate effects. For instance, the influence of cognitive biases on sustainable decision-making may be less straightforward, as biases can impede the adoption of circular practices. However, their impact can be mitigated through awareness campaigns and educational interventions.

Additionally, the strength and direction of causal effects can vary across different sectors, industries, and regions. Factors like policy frameworks, technological advancements, market conditions, and cultural norms can influence the magnitude and direction of causal relationships between circular economy variables.

Table 1 indicates the strength of the causal links between the pre-defined coded groups, as specified in Figure 7, as well as the overall occurrence frequency of the respective codes. The strength of the link is considered by using the number of occurrences [29]. The CSR variable is the most substantial causal effect in the CLD, with sustainable decision-making a close second. The strongest causal links between the coded groups are between A, B and C, which are current CE adoption, a sustainable society and the perceived need for sustainable decisions. The lowest causality ratings are found in code groups D and E, ecosystem capacity limits and unsustainable consumption and production patterns, which correlates with the minimal literature found on the topics. The weakest causal effects in the respective codes with the CLD were found in production management. The sustainability, sustainable and circular economy code frequencies were grouped.

Table 1: Code co-occurrence in CLD by code and code group

Code	Occurrence in CLD
○ Corporate social responsibility Gr=82	8
○ Sustainable decision making Gr=663	7
○ Sustainable decision Gr=662	6
○ Cognitive biases Gr=207	5
○ Circular development Gr=156	4
○ Environmental society Gr=8	4
○ Waste management Gr=234	4
○ Agricultural Gr=55	3
○ Ecosystem capacity Gr=231	3
○ Ecosystem growth Gr=231	3
○ Environmental Gr=7	3
○ Green energy Gr=10	3
○ Industrial Gr=50	3
○ Sustainability Gr=582	3
○ Sustainable development Gr=582	3
○ Circular economy Gr=154	2
○ Production management Gr=66	2
○ Sustainable Gr=581	2

Coded groups	Occurrence in CLD
A Gr=870; GS=6	9
B Gr=875; GS=8	9
C Gr=867; GS=4	9
D Gr=490; GS=6	7
E Gr=298; GS=2	4

In Figure 8, an extract of Atlas.ti the software used, is shown. The grounded frequencies in this figure as well as in Table 1, are the number of occurrences across all the literature used in this study. The highest grounded code and code groups are sustainable decision-making and sustainable society.

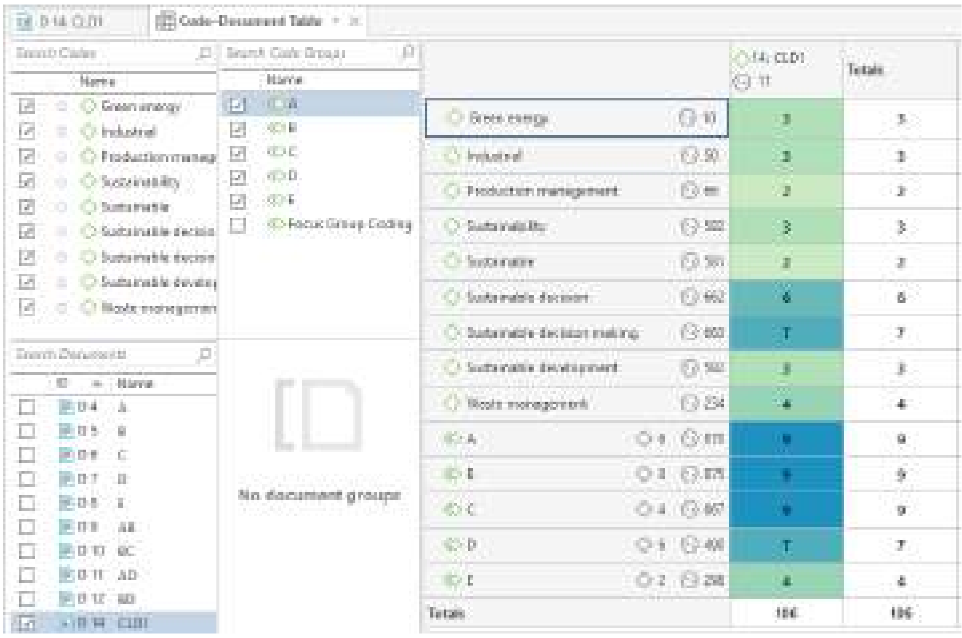

Figure 8: Grounded theory applied to codes and CLD

These insights can guide decision-making processes and support the development of effective strategies for promoting a more sustainable and circular economic system.

4.3 Implications of the results for decision-making in various fields

Developing effective strategies for promoting a more sustainable and circular economic system requires a thoughtful and informed decision-making process. Here are some key decision-making processes that can support the development of such strategies:

- Holistic analysis: Decision-makers should conduct a holistic analysis that considers economic, environmental, and social factors. This involves evaluating the potential impacts and trade-offs associated with different strategies and considering their long-term sustainability implications [30].
- Stakeholder engagement: Engaging relevant stakeholders, including businesses, policymakers, civil society organisations, and communities, is essential. Inclusive decision-making processes that incorporate diverse perspectives can lead to more comprehensive and socially acceptable strategies [31].
- Policy and regulatory frameworks: Establishing supportive policy and regulatory frameworks is essential for driving the transition to a sustainable and circular economy. Decision-makers should consider implementing measures such as incentives, regulations, and standards that encourage sustainable practices and reward circular business models [32].
- Collaboration and partnerships: Collaboration among various stakeholders, including government bodies, businesses, academia, and NGOs, is vital. Decision-makers should foster partnerships to share knowledge, resources, and best practices and collectively address systemic challenges [33].
- Innovation and research: Encouraging innovation and research is key to developing and implementing effective strategies. Decision-makers should support research and development initiatives that explore new technologies, business models, and practices that align with circular economy principles [34].
- Education and awareness: Promoting education and awareness among decision-makers, businesses, and the general public is crucial. Decision-makers should prioritise educational campaigns that raise awareness about the benefits of a circular economy, provide guidance on sustainable practices, and foster a culture of sustainability [35].

By integrating these decision-making processes, stakeholders can develop and implement effective strategies that promote a more sustainable and circular economic system. Continuous evaluation, monitoring, and adaptation of strategies based on feedback and new insights are also essential to ensure ongoing progress towards sustainability goals.

5 CONCLUSION

5.1 Summary of the paper

This paper explores using grounded theory to validate system dynamic models for CE sustainability transitions. The research highlights the iterative process of validating a system dynamics model based on a literature review. Grounded theory is employed to validate the relationships and feedback loops in the model, ensuring that it aligns with real-world dynamics and captures the complexities of CE sustainability transitions. The integration of the grounded theory and the CLD presents the value of identifying real-world links between the CE variables and the external environment. In Figure 6 the connections between the codes from the grounded theory and the CE is seen.

5.2 Limitations and future research directions

While efforts to promote a sustainable and circular economic system have gained momentum, there are certain limitations and areas for future research that warrant attention:

- Data availability and quality: Limited availability and quality of data on CE indicators pose challenges for decision-making. Future research can focus on improving data collection methods, standardising metrics, and developing comprehensive databases to enhance the accuracy and reliability of sustainability assessments.
- Complexity and interdependencies: The CE system has numerous interdependencies and feedback loops. Understanding and modelling these complexities present challenges. Future research can explore advanced modelling techniques, such as agent-based modelling or network analysis, to capture the intricacies of circular economy systems and improve decision-making processes.
- Policy integration and coherence: Coherence and integration across various policy domains are crucial for achieving a sustainable and circular economy. Future research can delve into approaches for integrating policies across sectors, addressing potential conflicts, and identifying synergies to foster a comprehensive and coordinated policy framework.
- Behaviour change and consumer engagement: Shifting consumer behaviours and promoting sustainable consumption patterns are pivotal for circular economy adoption. Future research can explore effective strategies to incentivise behaviour change, overcome cognitive biases, and enhance consumer engagement through targeted interventions, communication campaigns, and nudging techniques.
- Business models and market transformation: Transitioning towards circular business models requires overcoming barriers and incentivising transformative changes. Future research can explore innovative business models, financial mechanisms, and regulatory incentives to facilitate market transformation and encourage the widespread adoption of circular practices.
- Social and equity considerations: Ensuring social inclusiveness and equity within a circular economy is critical. Future research can investigate the social implications, distributional effects, and potential trade-offs of circular economy strategies. This includes exploring how circular practices can contribute to job creation, social well-being, and reducing inequalities.
- Global collaboration and policy transfer: The circular economy is a global challenge that requires international collaboration and knowledge sharing. Future research can explore mechanisms for facilitating cross-country collaboration, policy transfer, and learning from successful circular economy initiatives worldwide.

Addressing these limitations and pursuing these future research directions can provide valuable insights and tools to policymakers, businesses, and stakeholders in advancing sustainable and circular economic systems, ultimately leading to a more resilient and prosperous future.

5.3 Practical applications and recommendations

The validated causal relationships can provide valuable insights for decision-making processes in various fields. Stakeholders, including policymakers, businesses, and researchers, can use the validated model to inform their strategies, policies, and interventions related to the CE. The validated model can educate and raise stakeholders' awareness about the CE. It can serve as a basis for educational programs, training materials, and workshops aimed at fostering a better understanding of the interdependencies and impacts of CE variables. The study can pave the way for future research directions in behavioural system dynamics within the context of the CE. This includes exploring more complex system dynamics models, refining the causal relationships, and conducting empirical studies to validate the model's findings.

ABSTRACT

Low- and middle-income countries (LMICs) need better access to cost-effective and value-adding medical devices to minimise their reliance on imported and donated equipment. Most of this equipment, which makes up 80% of the existing equipment base, is unsuitable for local needs and cannot be maintained due to a lack of local infrastructure. Rather than completely overhauling the system, innovation systems (IS) should refocus already-existing tasks, resources, and activities on the localisation of the medical device industry, putting into place prioritisation strategies. The author conducted a Structured Review (SR) to understand the current state of knowledge and establish a future research direction on localisation frameworks supporting the medical device IS in LMICs. The SR aimed to synthesise and investigate the evidence from the literature regarding the existing artefacts used to facilitate medical device localisation in LMICs.

Keywords: localisation, medical devices, innovation system,

1 INTRODUCTION

Appropriate health technologies are essential for any functional health system. However, due to economic constraints experienced by several developing countries, the health sectors of these countries have to rely heavily on donated equipment. Many of these donations are sent with good intentions but do not appropriately meet the contextual needs, i.e. the majority of this equipment is unsuitable for local conditions and cannot be maintained due to a lack of local infrastructure and/or resources [3, 4].

These donations frequently bypass the selection and procurement systems in a recipient country. As a result, insufficient thought is given to the actual local requirements, the prevalence of disease and degree of care, the number of device users (staff members) and their capabilities, and the level of technical skill available to provide maintenance. This oversight thus results in inappropriate technologies being implemented. Further contributing to this, is the poor communication between donors and recipients about their contextual needs [4].

The outbreak of the COVID-19 pandemic in 2020 that shook the healthcare sector of various nations intensified the urgency for African governments to invest in the local production of various medical health technologies like medical devices, vaccines, and diagnostics. This was because there was a high demand for equipment like ventilators to combat the pandemic globally, but they were in short supply. During that period, it was evident that Africa was neither self-sufficient nor adaptable enough to repurpose local pharmaceutical or device capabilities to produce medical health technology at the scale necessary to quickly address the pandemic's concerns, resulting in severe shortages [5].

Investing in the local medical device industry, particularly its manufacturing capabilities, could address the problem of inappropriate medical devices emerging from donations and a lack of preparedness for a health emergency. Hence, this study will design and develop an innovation system framework for strategic decision-making to support the localisation of medical devices in South Africa. Furthermore, insights and policy support guidelines will emanate from this study. This framework will be designed for the South African medical device industry, and can potentially be adapted for other LMICs.

The author conducted a Structured Review (SR) to understand the current state of knowledge and establish a future research direction on the topic of localisation frameworks supporting the medical device IS in LMICs. The SR aimed to **synthesise and investigate the evidence from the literature regarding the existing artefacts that have been used to facilitate medical device localisation in LMICs**. These artefacts could be in the form of frameworks, tools, or models. The following research question was explored: **"What innovation and development artefacts exist to facilitate medical device localisation in LMICs?"**. The gaps identified from the synthesis of the existing artefacts will serve as the foundation for designing and developing a decision-support framework for localising medical devices in South Africa.

2 METHODOLOGY

The SR followed a six-step methodological approach defined by Arksey and O'Malley [6] which involved (1) identifying the research question(s), (2) identifying the relevant studies, (3) study selection, (4) charting the data, (5) collating, summarising, and reporting the data and (6) consultation (optional stage). A bibliometric analysis of the data was conducted to observe the evolution of the scientific literature and identify unique characteristics of the associated knowledge domain. The overall reporting of the SR was guided by the Preferred Reporting Items for Systematic Reviews and Meta-analysis extension for Scoping Reviews (PRISMA-ScR) checklist.

2.1 Selection Process

The literature search was guided by two electronic databases: Scopus and Web of Science (WoS). Both WoS and Scopus provide broad coverage of several disciplines, including nature, medicine, health sciences, engineering, and technology and, therefore, are extensively utilised for academic research [7]. The search was also extended to include a review of grey literature of other documents from organisational websites. The table below indicates the search strings that were used in both Scopus and Web of Science, focusing on the title, abstract and keywords as indicated:

Table 1: Table showing the search strings of the Scopus and WOS databases

Database	Search string
Scopus	TITLE-ABS-KEY (model OR framework OR system OR tool) AND TITLE-ABS-KEY (“medical device” OR “medical equipment” OR “medical technolog*” OR “medtech”) AND TITLE-ABS-KEY (“local manufactur*” OR local* OR benefi* OR self-suffici* OR “localisation”) AND TITLE-ABS-KEY (“africa” OR “lmic” OR “developing countr*”)
Web of Science	[(((TI=(model OR framework OR system OR tool)) AND TI=(“medical device” OR “medical equipment” OR “medical technology” OR “medtech”)) AND TI=(“local manufactur*” OR local* OR benefi* OR self-suffici* OR localisation)) AND TI=(“Africa” OR “LMIC” OR “developing countr*”)] OR [(((AB=(model OR framework OR system OR tool)) AND AB=(“medical device” OR “medical equipment” OR “medical technology” OR “medtech”)) AND AB=(“local manufactur*” OR local* OR benefi* OR self-suffici* OR localisation)) AND AB=(“Africa” OR “LMIC” OR “developing countr*”)] OR [(((AK=(model OR framework OR system OR tool)) AND AK=(“medical device” OR “medical equipment” OR “medical technology” OR “medtech”)) AND AK=(“local manufactur*” OR local* OR benefi* OR self-suffici* OR localisation)) AND AK=(“Africa” OR “LMIC” OR “developing countr*”)]

Articles retrieved were critically evaluated to be included in the SR if they met the following inclusion criteria: (1) articles published in English; (2) articles with accessible full texts; (3) articles that present a model/tool/framework that features the innovation system Articles were excluded if (1) they were non-English language documents; (2) they featured studies not conducted in LMICs; (3) they were focused on the technological development and bench/ clinical testing of a medical device exclusively with no extension to framework development; (4) the articles focused on any other products except medical devices. A total of 236 articles were retrieved from the search, with 218 originating from Scopus and 18 from Web of Science databases. All 236 articles were subjected to a three-stage screening process as indicated in Figure 1 below.

2.2 Data Extraction and Analysis

Using R with the package *bibliometrix* [8], the 47 articles retrieved from both Scopus and WoS and identified before the second and third screenings were analysed. All 47 articles were included in this analysis because of the possibility of discovering valuable trends from their bibliotex data. Data was analysed in terms of document statistics, collaboration index, journal impact, country productivity, document citation analysis, and keywords. The main goal was to uncover the emerging trends and patterns over the years, the collaboration patterns, identifying knowledge gaps, and positioning intended contributions to the field [9]. Further analysis aimed to identify and map any actor-institutional links and information routes used to create, generate, and disseminate innovation [10].

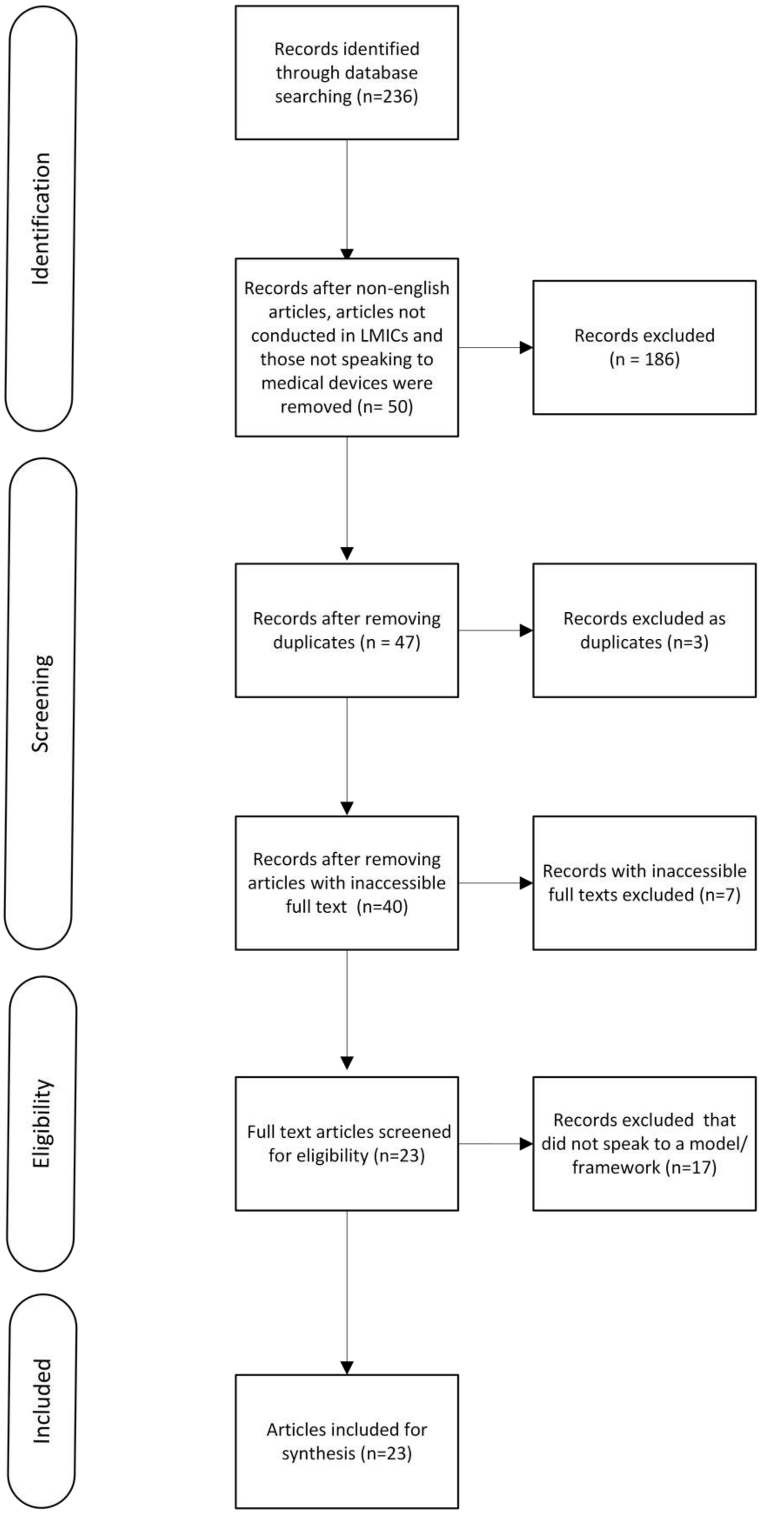

Figure 1: Prisma ScR flow diagram for this structured review

3 RESULTS AND DISCUSSION

Results from the bibliometric analysis are presented in this section to reflect (i) growth and trends of frameworks or models in terms of publication output, distribution, source, and citations; (ii) prolific scholars, affiliations, and social networks; (iii) thematic focus of the field of localisation frameworks.

3.1.1 Descriptive Statistics

Analysis from *Biblioshiny* revealed that the structured review consisted of 29 articles, 9 reviews, 5 conference papers and 1 representative each for the conference proceedings, book chapter, editorial and notes; traversing a timespan from 1995 to 2022. This analysis revealed an 8.48% annual growth rate of scientific production. There was a significant increase in scientific output between 2017 and 2022 and a notable increase in citations per year from 2010, indicating an increased interest in localisation artefacts for medical device development in LMICs.

3.1.2 Science Mapping

Analysing the Top-Author's Production of articles between 2010 and 2022 and their countries of affiliation and keywords revealed that most of the research in this field is conducted in the developed world. Only two LMICs are featured in this map: South Africa and Tanzania, which indicates that there is still limited contribution to knowledge regarding localisation artefacts in LMICs. This is suggestive of both a mushrooming discipline and the necessity for LMICs to invest in the creation of localisation-related knowledge, as they have a greater awareness of their setting than developed nations.

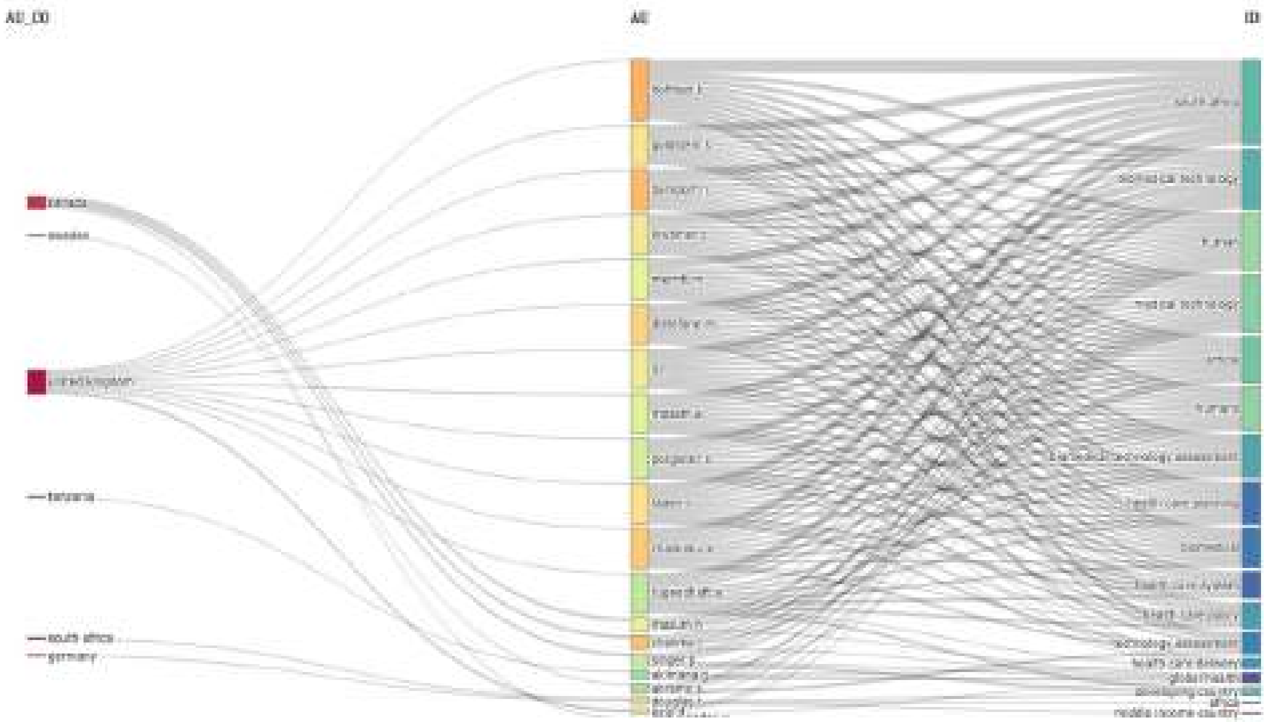

Figure 2: A three-field plot of countries, authors, and identified keywords: The emphasis is placed on the height of each box and thickness of the connecting lines; the taller the box, the more significant; and the thicker the lines' correlation, the more information or volume of work was produced [1]

Notably, Figure 2 above reveals that a lot of work is being done in South Africa regarding the localisation of medical devices owing to the thickness of the connecting lines as well as the highest height of its box. This could be attributed to the fact that South Africa has a well-established medical device sector in terms of companies registered to sell medical devices, compared to several other LMICs [5]. This rightly positions South Africa as a study setting for this research.

An analysis of the top 20 organisations contributing to the dataset further revealed that there were 8 LMIC institutions featured among the top 20 contributing to this dataset. A holistic analysis of Figures 2 and 3, demonstrates that collaboration exists between LMICs and non

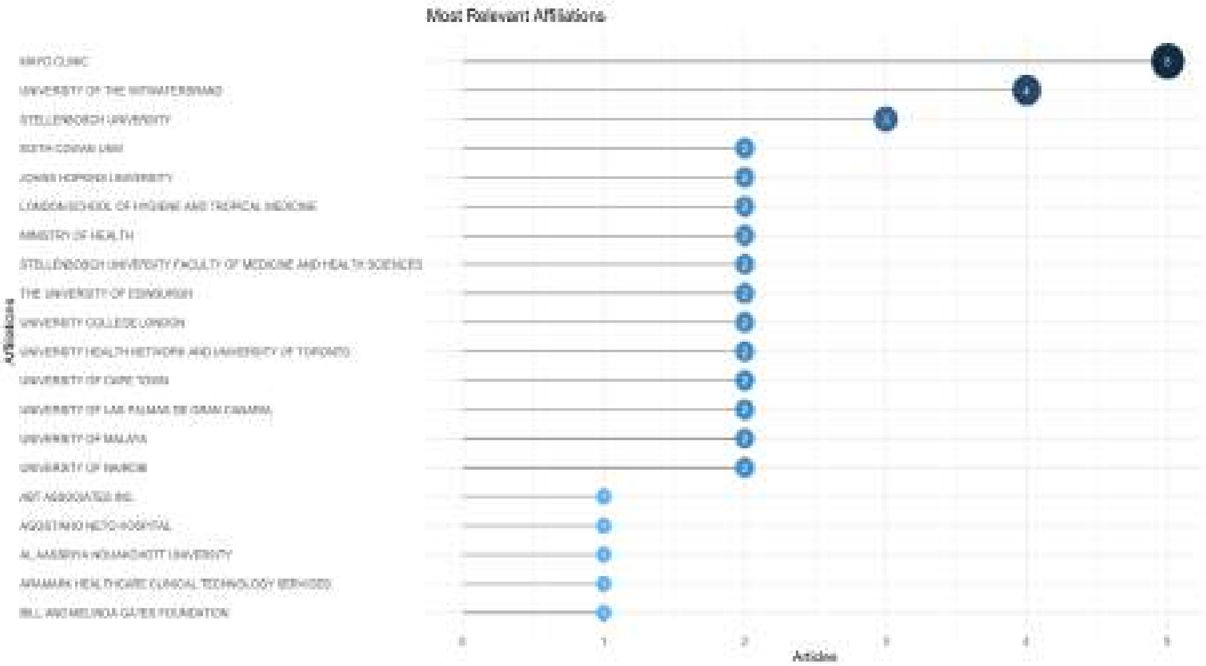

Figure 3: Most relevant institutions and affiliations.

LMICs however with the field dominated by non-LMICs. Notably, universities and authors from non-LMICs make up the majority of contributors. According to the innovation system framework, universities play a key role as drivers in the knowledge-economy, which could potentially be their lead role played in this context [11].

3.1.3 Thematic Mapping and Categorisation

ATLAS.ti software [12] was used to assemble, disassemble and reassemble the data. Grounded theory methodologies were utilised and preferred during the coding cycles because of the meticulous attention paid to the process of theorisation [13]. The first coding cycle produced 88 codes which were later reviewed and iteratively coded into 43 codes that finally generated five themes/categories namely: localisation artefacts, localisation requirements, defining localisation, localisation case studies and rationale for localisation.

Table 2: Table showing the representation of frameworks across three time slices

Frameworks	1995 - 2010	2011 - 2016	2017 - 2022	Totals
Business models	6	0	1	7
Decentralisation	0	3	0	3
Frugal innovation	0	0	9	9
Health Technology Assessment	1	12	14	27
Maker Hub	0	0	5	5
Medical Technology Score (MTS) by WHO	0	2	0	2
Open source - open science architecture framework	0	5	1	6
Path following, skipping and creating	0	1	0	1
Platform based framework	0	0	3	3
TIS framework	0	0	3	3
Totals	**7**	**23**	**36**	**66**

Table 2 above indicates that the subject on frameworks began building up between 2011 - 2016 and became exceedingly apparent during the later time slice of 2017-2022. This indicates that the field has been developing since the first time-slice. Some of the identified artefacts were focused on steering innovation at the onset of device discovery and risk analysis; for example, the concept of “frugal innovation”, “path following, skipping and creating” whereas the majority were employed post-device production (ready for deployment) and focused on aspects like procurement and device usability. The “Health Technology Assessment (HTA)” tool and the Medical Technology Score (MTS) by WHO are examples of such. Table 3 further elaborates on the frameworks that were focused on steering/guiding innovation.

Table 3: Table describing the frameworks obtained from the Coding process

Framework	Description	Author and year
Frugal innovation	This involves applying the concept of doing and achieving more with less [14] and being able to develop appropriate, cost effective, adaptable, and accessible solutions for users in resource constrained settings [15].	Chakravarty (2022), Waran et al., (2022)
HTA	Health technology assessment (HTA) is a multidisciplinary approach that uses clinical effectiveness, cost-effectiveness, policy and ethical perspectives to provide evidence upon which rational decisions on the use of health technologies can be made. It can be used for a single stand-alone technology (e.g. a drug, a device), complex interventions (e.g. a rehabilitation service) and can also be applied to individual patient care and to public health.	Blaauw et al., (2022), Chakravarthi (2013), Dang et al., (2016), Edney et al., (2022), Govender (2011), Krubiner et al., (2022), Simiyu et al., (2010), Kumar et al., (2014), Mukherjee (2021), Patterson et al., (2019)
Maker Hub	A model designed to address challenges in the social sector through creative collaboration, leadership and governance processes for management of locally based physicians, nurses and biomedical engineers. The funding approach used allowed for mechanisms for problem-solving to ensure its long-term sustainability.	Ayah et al., (2020)

Open source - open science architecture framework	Utilising a hybrid approach of integrating agnostic. This framework entails setting specialised environments for fruitful interaction especially between the open-source technology, healthcare interoperability standards and Total Quality Management principles. Such platforms include for example the 3D Slicer ecosystem and the UBORA E-platforms [16]. Such platforms provide opportunities for medical and engineering education, training and for biomedical research translation.	Harding (2016), Ruiz-alzola et al., (2018)
Medical Technology Score by WHO	The WHO Priority Medical Devices Project also makes use of the "availability matrix," which relies on WHO survey technology to determine the list of preventive, diagnostic, therapeutic, and assistive medical devices needed for the treatment of 15 diseases.	Fatunde & Bhatia (2012)
Path following, skipping and creating	According to this model, countries are firstly divided into three categories of technological capabilities, namely low, average and high. Then, each country attempts to absorb and localise technology based on its level of technological capability. In other words, countries with low capability start their path towards localisation of technology by focusing on mature technologies thereby adapting the path following approach. Similarly, the acquired technologies will be changed into new and emerging technologies due to an increase in technological capabilities; thereby employing the path - skipping model for average capabilities and the path creating for the high technological capabilities [17].	Shafia et al., (2015)
Platform based framework	This framework is characterised by a holistic understanding and combination of innovation and transaction platforms. It draws from the synergism between the engineering and economic perspectives to derive meaning from an ecosystem.	Herman (2020)
Context-specific TIS framework	According to Carlsson and Stankiewicz [18], a Technological Innovation System (TIS) is a "network of agents interacting in a specific economic/industrial area under a particular institutional infrastructure or set of infrastructures is involved in the generation, diffusion, and utilisation of technology". This framework incorporates aspects of context as technology generally develops differently in various contexts. Also, it is defined in terms of knowledge/competence flows rather than flows of ordinary goods and services.	Salie at al., (2019)

3.3 Thematic Mapping and Categorisation

ATLAS.ti software [12] was used to assemble, disassemble and reassemble the data. Grounded theory methodologies were utilised and preferred during the coding cycles because of the meticulous attention paid to theorisation [13]. The first coding cycle produced 88 codes, which were later reviewed and iteratively coded into 43 codes, finally generating five themes/categories: localisation artefacts, localisation requirements, defining localisation, localisation case studies and rationale for localisation.

Some of the identified artefacts were focused on steering innovation at the onset of device discovery and risk analysis; for example, the concept of “frugal innovation”, “path following, skipping and creating” whereas the majority were employed post-device production (ready for deployment) and focused on aspects like procurement and device usability. The “Health Technology Assessment (HTA)” tool and the Medical Technology Score (MTS) by WHO are examples of such.

The HTA was significantly outlined in several papers as a preferred decision support tool for guiding the medical technology industry. The HTA tool has successfully been employed in several developed countries and produced significant results, especially when embedded with economic evaluation and considering the contextual and social aspects [19, 20]. Its use in the LMICs is still limited but is rather increasing with continuous representation of the HTA agents in international HTA networks [21].

In practice, HTA is constrained in that it pays less attention than is necessary to the systematic assessment of significant social, organisational, and ethical consequences of the health technology in question and instead focuses primarily on economic evaluations of cost-effectiveness and budget impact [22]. Also, HTA is primarily focused on product development instead of the holistic sectoral/system development. According to Mukherjee [21], a systems approach to HTA could be used to evaluate health innovations holistically, assisting policy makers in determining which innovations improve the health system and fill gaps. Additionally, HTA would allow for efficient utilisation of existing resources and wastage reduction allowing for equity gains. Gains realised in equity and efficiency would significantly lessen the trade-offs associated with sustainability.

The review highlights the potential for HTA to be used as a decision support framework aiding localisation in LMICs. However, this would involve incorporating a relatively new concept called the “early HTA” that allows for the potential value of a new health technology to be determined at an early stage of its development. The early HTA concept extends the traditional HTA that informs coverage/reimbursement decisions at the latter stages of device development. The early HTA thus informs early research, development, and investment decisions. There have been numerous methodological studies and implementations of early HTA in recent years. However, it is still unclear how early HTA can be included in the innovation process and fit in with routine healthcare decision-making, which presents a research gap [23].

Other artefacts that were identified as decision support tools and were predominantly context-based include the concept of frugal innovation that involves developing appropriate, cost-effective, adaptable, and accessible solutions for users in resource constrained settings [15]. The frugal innovations are further characterised by significant cost reduction, focusing on core functionalities and optimal performance [24].

To address shortage of technological capabilities which is key for localisation of medical devices, models such as the “Maker Hub” were introduced aimed at addressing challenges in the social sector through creative collaboration, leadership and governance processes for management of locally based physicians, nurses and biomedical engineers [25]. Another such platform was the Open source - open science architecture framework focused on setting specialised environments for fruitful interaction especially between the open Source technology, healthcare interoperability standards and Total Quality Management principles. Such platforms include the 3D Slicer ecosystem and the UBORA E-platforms [16]. These platforms provide opportunities for collaborative engagement between stakeholders in the innovative space, medical and engineering education, training and biomedical research translation using best practices, ensuring improved research, product and service delivery outcomes [26].

The "Path following, skipping and creating" model was designed to ensure that countries develop and increase their technological capabilities [27]. According to this model, countries are firstly divided into three technological capabilities categories: low, average and high. Then, each country attempts to absorb and localise technology based on its technological capability. In other words, countries with low capability start their path towards localisation of technology by focusing on mature technologies thereby adapting the path following approach. Similarly, the acquired technologies will be changed into new and emerging technologies due to increased technological capabilities; thereby employing the path - skipping model for average capabilities and the path creating for the high technological capabilities [17].

Herman, et al. [28] elucidated on the concept of "technology platforms" defined as technology that provides a software foundation for interactions and transactions between several actors and can be used in healthcare to foster communication, data analysis, and opportunities to increase patient healthcare education, especially in resource-constrained settings. This platform-based tool was used to inform and support platform owners in designing, developing and implementing healthcare-related platforms and the ensuing ecosystems. They can potentially improve the quality and accessibility of healthcare, particularly in the rural areas of developing countries.

The Context-specific TIS framework introduced by Salie, et al. [29] was tailored towards understanding how well the functions of an orthopedic TIS are performing over time hence being able to gauge the capacity of the TIS. This framework incorporates aspects of context as technology generally develops differently in various contexts. Also, it is defined in terms of knowledge/competence flows rather than flows of ordinary goods and services which are important factors to consider in localisation. The "Medical Technology Score" metric designed by WHO was developed as a comparative metric to judge the levels of technology available in health facilities and ascertain whether the existing technologies meet the disease burden locally [30]. This metric was contextualised around the disease burden and inclined towards being product-centered as compared to the TIS framework which is system-centered.

3.4 Research Gap and Future Direction

This review found that most of the existing literature regarding localisation artefacts focuses on the TIS and mainly gravitates toward post-device production (ready for deployment) and aspects like procurement and device usability. There was scanty literature on how the Sectoral IS has been used to understand the flows between actors in the medical device sector [31] as opposed to the conventional focus on the dynamics of technological development. Therefore, the SIS can be used as a framework to measure the performance of technology change in the medical device sector over time, which presents a focus for this research project [32].

According to Hekkert, et al. [31], there is a need to influence both the speed and direction of innovation and technological change, whereby technological change incorporates the holistic development of the technology concerning its innovation system, a process called "the innovation process". Steering innovation and technological change as pointed out by the existing literature largely involves developing the technological capabilities of the concerned actors and stakeholders. The term "technological capability" refers to a set of skills, equipment, knowledge and all attributes that can aid an organisation in the production, learning, improvement and development of manufacturing and operational processes [33].

Although the requirement for actors to possess appropriate technological capabilities for localisation has been highlighted, there was scarce literature on the specific actors' capabilities required as well as their corresponding functions needed for the successful localisation of the medical device IS. This demonstrates the need to identify and match IS functionality to actor capabilities, particularly when focusing on the South African medical device IS. This knowledge would guide various actors on the appropriate path to take regarding the localisation of medical devices in SA.

4 CONCLUSION

Further study following this structured review will involve conducting an industry survey to identify the existing policy priorities for localisation in the medical device industry in South Africa and thereafter, various case studies will be conducted of failed medical devices. This will all be in a bid to identify how various IS functions emerge over time and support the relevant actors. Using Events History Analysis, event-based narratives will be obtained and utilised to gain an in-depth understanding of the positive and negative significant milestones that led to a particular outcome and, more importantly, to uncover valuable insights that will be utilised for framework development [34].

ABSTRACT

The innovation of technologies to assist the construction industry with asset information management has gained attention since the complexity of projects is also increasing, making it difficult to correlate data without computer systems. Hence, the construction industry is shifting from the traditional method of managing information that involves handwritten and printed documents into the modernised technique that entails digitalising data. However, the South African construction industry is slowly adopting digital transformation that can be initialised by implementing Building Information Modelling (BIM) due to factors not limited to ambiguous economic benefits and not knowing where to start. The main contribution of this paper is to highlight the need for modernisation in the South African construction industry and demonstrate the benefits of using BIM through a comparison of BIM with traditional methods using Multicriteria Analysis (MCA). The MCA evaluates five objectives: the Top Strategic Initiatives for the SA construction industry, Cost and Expenses, Quality, Asset Information Management Processes, and Outputs.

Keywords: Asset Information Management, Building Information Modelling (BIM), Multicriteria Analysis (MCA)

1 INTRODUCTION

The process of acquiring, organising, and integrating asset data is vital in ensuring the smooth operation of construction projects, and most countries have invested in advancing asset information management to enhance the performance of construction projects generally [1]. According to [2], the Western world is improving asset information management through the use of BIM implementation that results in a digital transformation strategy by merely organising and digitalising information.

Digital transformation has been accelerated in different industries nowadays and it involves using technology in numerous processes. The United Nations (UN) highlights that in the past two decades, digital technology has been embraced by 50% of the developing world's population, and it believes that the 17 Sustainable Development Goals (SDGs) can be achieved more quickly owing to digital advancements [3]. With this, BIM implementation can help in the fulfilment of several SDGs namely, SDG 3 for good health and well-being, SDG 6 for clean water and sanitation, SDG 8 for decent work and economic growth, SDG 9 for industry, innovation and infrastructure, SDG 11 for sustainable cities and communities and SDG 12 for responsible consumption and production. This paper, therefore, outlines how BIM helps achieve these SDGs, thus explaining the need for immediate modernisation of asset information management techniques and the benefits of BIM over the traditional approach of asset information management that involves the use of hard copies.

The multicriteria analysis (MCA) is used to explicitly compare the BIM method to the traditional technique due to its suitability to filter options before applying more in-depth quantitative analysis as well as to compare options when implications are difficult to quantify as outlined by [4]. Hence, it is the best tool that can be used to analyse the two options, particularly BIM and the conventional method for asset information management.

2 LITERATURE REVIEW

The need to extensively increase awareness of the importance of managing and maintaining existing infrastructure as well as considering its full-service life has globally increased owing to the necessity to improve the poor service performance of construction projects as well as the loss of asset value due to poor maintenance. According to [5], South African municipalities are worried about the deterioration of the infrastructure that is built as well as the one that already exists with the challenge of balancing the demand and the supply of infrastructure. As a result, there is an increase in abandoned infrastructure, high informal settlements, poor municipality service delivery like the health facilities, constant load-shedding, collapse of infrastructure and poor quality of infrastructure. These challenges are immensely significant in a large population of impoverished people like the township areas in South Africa. Most of these challenges are merely due to poor asset information management.

Asset information management can be effective and efficient if it allows proper time and resource management to produce the desired results and the right people to use the correct information at the right time to make the right decisions [6]. Moreover, the correctly stored information facilitates effective management, planning, monitoring and controlling, operations, maintenance and reporting to improve the value of the asset information. With this, the poor asset information management in the South African construction industry, as well as substandard information storage, has led to the construction of inferior quality infrastructure and poor infrastructure maintenance that give rise to the collapse of the built assets, buildings to be abandoned as well as ineffective and inefficient energy infrastructure resulting in increased power cuts. If asset information is up to standard, then the resources would be properly managed to produce the desired output, and the right people would make the right decisions using accurate information.

According to [7], asset management (AM) generally helps provide the required infrastructure by enabling asset assessments, creating, and maintaining asset registers, defining roles and responsibilities for the AM process, maintaining and protecting assets through accounting, managerial, and information systems of the organisation. The study by [1] highlights that assets are analysed in two aspects namely, the financial perspective for the economic value of an asset such as focusing on its financial value, reducing costs as well as increasing return on investment and engineering perspective for establishing information systems and facilitating decision making throughout the asset lifecycle, particularly in asset scheduling, maintenance and reliability. As a result, effective asset management creates opportunities for the provision of affordable, effective and efficient infrastructure in a transparent and accountable manner. In order to achieve this, an asset management toolkit, illustrated in Figure 1, is used to assist the construction industry in managing infrastructure assets accordingly.

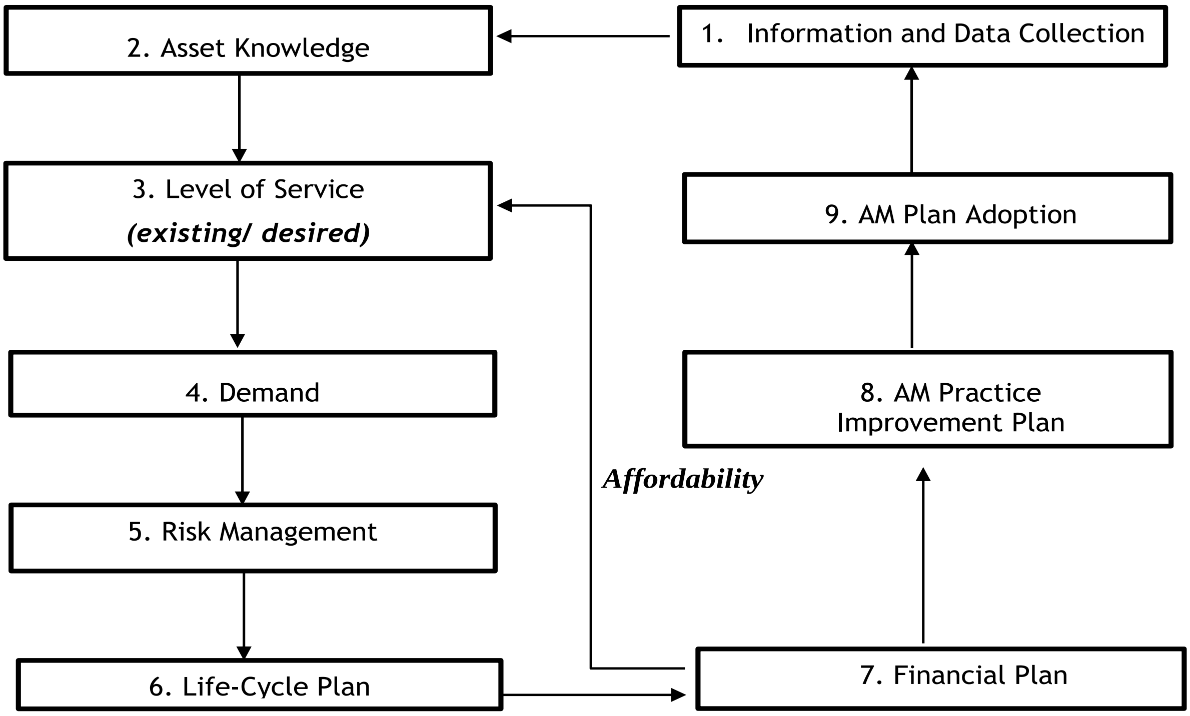

Figure 1: Basic AM Toolkit (Adopted from [5])

The AM toolkit outlines the elements of infrastructure asset management (IAM) in chronological order. According to [5], IAM starts with gathering information and data, which involves identifying what information is already available, assessing its relevance and validity, highlighting any information gaps and assumptions, and maximising the use of information that is already available. This immensely affects the asset knowledge which results in the initial information and data collection element of the toolkit. Due to the unstructured, inconsistent and unstandardised information and data collection methods that result in the use of traditional method of asset information management, the first two stages of the toolkit produce substandard results.

The level of service consists of the existing and the desired levels that are influenced by stakeholders. These include customers' needs as well as technical and legal requirements; the difference between the two levels needs to be minimised by the asset management strategies [7]. However, a lack of advanced technologies in the asset management strategies makes it even more difficult to reduce the service level gap due to the low performance associated with the deficiency of innovative practices to improve efficiency, reliability, quality, comfort, sustainability and affordability which are the main criteria to determine the acceptable service life of an asset as outlined by [5] & [7].

According to the AM toolkit, the affordability of an asset is determined by the level of service and the financial plan. This is due to the budget restrictions associated with the financial plan which in turn affect the quality of the construction of an asset, one of the criteria for service life. The study by [8] discusses the importance of the project management iron triangle that highlights the importance of quality and that it is constrained by scope (features, functionality), time (schedule) and cost (resources, budget). In the toolkit, the financial plan assesses the economic viability of infrastructure using a financial forecast that details an asset's costs and revenues; preference is given to construction projects with less costs than revenue [5].

Moreover, the life cycle plan is an intentional response to the strategic vision of the organisation's demands, gaps in the level of service, pattern of anticipated future demand, demand management activities, and risks [5]. The plan details how the project is connected to each requirement, and it shows the approach taken to manage the asset life cycle from the pre-construction phase to the post-construction phase of the built asset. With this, the demand element of the toolkit ensures the right balance between the supply and demand of the infrastructure and its services, while the risk management helps in the identification, analysis and evaluation of the risks as well as providing the risk responses/ treatments [5].

Similarly, all levels of the asset lifecycle require a continuous process of improving infrastructure management practices. Hence, the AM practice improvement plan allows continuous infrastructure improvement, and it requires a sufficient budget and reasonable schedule to achieve the infrastructure asset management plan milestones [5]. The AM plan is then adopted and implemented when the comprehensive infrastructure plan which includes infrastructure overview, issues and risks, level of service targets and financial forecasts has been consolidated [5].

Considering the AM toolkit for the South African construction industry, some of its elements can be drastically enhanced by adopting technology to facilitate its functionality, through modernising the information and data collection, asset knowledge, level of service and the aspects of the asset life cycle as well as the financial attributes. The study by [2] has already established a relationship between AM and BIM, an innovative practice that assists AM by providing a digital transformation strategy. This relationship is outlined in Figure 2.

According to [2], organisational information requirements (OIR) entail identifying and categorising the necessary information to enable asset management at an organisational level, which may include posing questions that may help an organisation determine whether the objectives will be accomplished or not. As a result, asset information requirements (AIR) entail providing answers to questions identified in the OIR at the asset level as well as identifying and capturing the data needed to create and maintain the asset [2] & [1]. Moreover, information management for construction projects always starts with capturing the client's information needs to make sure the project is completed in a way that satisfies the client. With this, Employer's/Exchange Information Requirements (EIR), which specify the data that must be provided along with the practices and standards to be used for building projects, are the requirements needed for projects that use BIM to ensure that the project is delivered as per contract and to the satisfaction of the client [6].

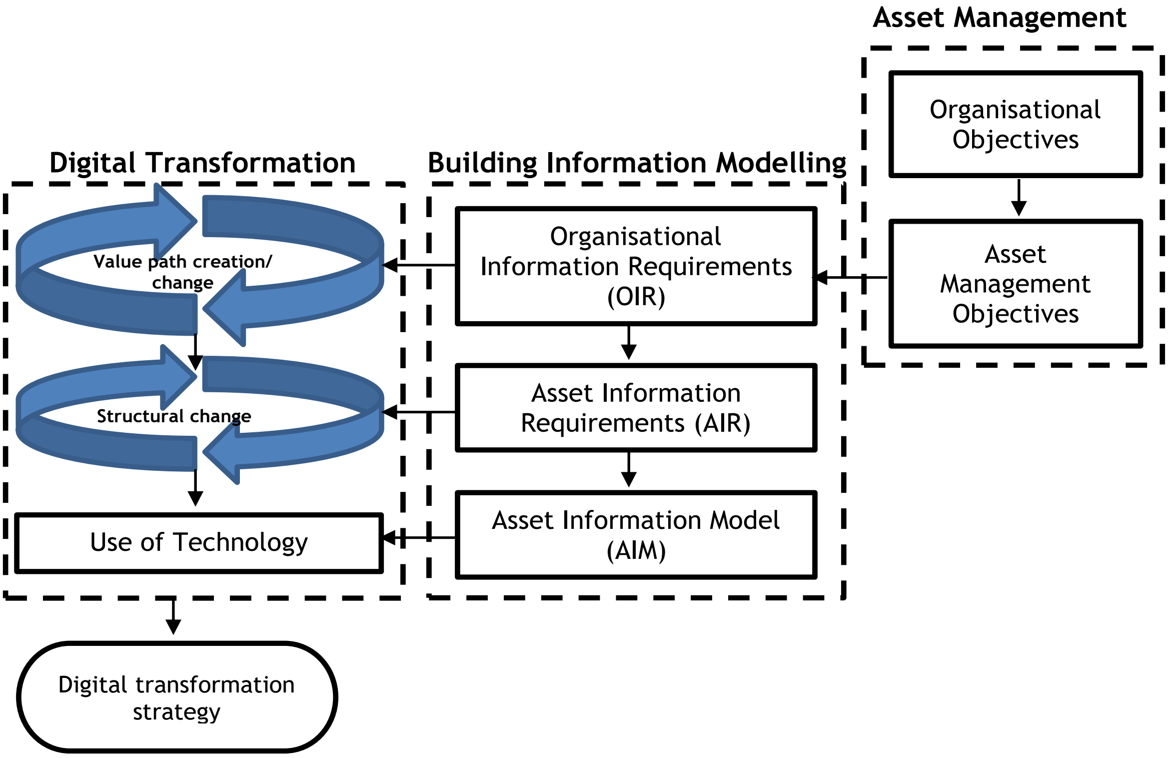

Figure 2: Digital transformation framework for BIM (Adopted from [2])

According to [9], the asset information model (AIM) results from the project information model (PIM) which stores structured digital data for the design and construction phases to improve infrastructure asset management in the post-construction phase. When the project has been completed and accepted, it is then handed over and the PIM is transferred into AIM. This involves the use of technology to provide the digital transformation strategy which results in changes of how the structures are created and managed as compared to the traditional method. Table 1 provides an overview of the BIM requirements and their respective outputs.

Table 1: Overview of BIM Requirements (Adapted from ([9] & [2])

	Level	Requirements	Deliverables
Stakeholders based	Organisational	Organisational Information Requirements (OIR)	Organisational Objectives Asset Management Objectives
Contract based	Asset	Asset Information Requirements (AIR)	Asset Information Model (AIM)
	Project	Employer's Information Requirements (EIR)	Project Information Model (PIM)

It is possible to list the vital distinctions between the implementation of BIM and the conventional approach to managing assets by comparing the world of traditional corporate to modern digital business, and Figure 3 outlines this comparison. According to [10], the world of digital business Is dynamic with high levels of competition, uncertainty, knowledge creation, innovation and multiple ways of doing business. As a result, this provides the basis of the dynamic capabilities of a firm which is the ability to adjust to changing environments, thus supporting factors not limited to the company's market penetration and continuous adaptation to the increased complexity of projects, technology and shifting environments. On the contrary, the world of traditional business is stable with low levels of competition and ways of doing business [10]. Moreover, it focuses on knowledge utilisation rather than creation, unlike the world of digital business.

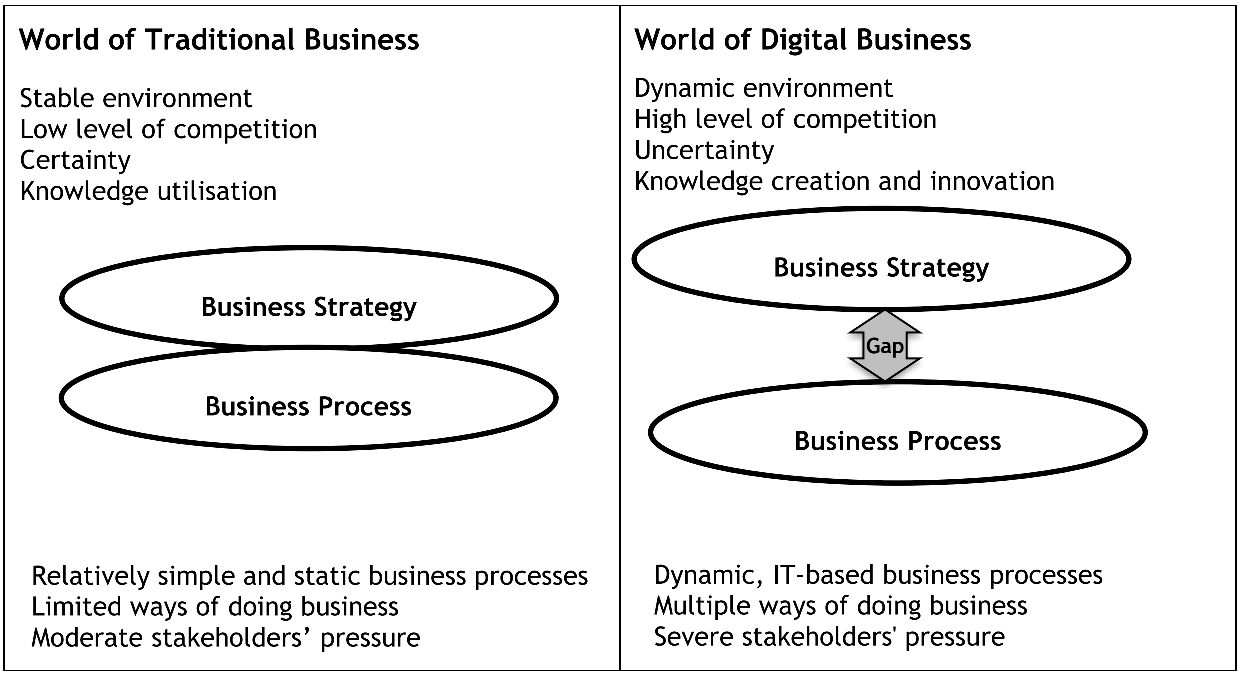

Figure 3: Comparison between the world of traditional and modern digital business (Adopted from [10])

The MCA is additionally used to compare the BIM method to the traditional technique since their influence and impact are difficult to quantify, and an in-depth quantitative analysis of the MCA outcome is done in the result analysis section of this paper. There are five objectives of the MCA namely, the top strategic initiatives for the South African construction industry, asset information management processes, asset information management outputs, cost and expenses and quality.

2.1 The top strategic initiatives for the South African construction industry

The company [11] identified critical strategic objectives that would assist the development of the South African construction industry, which include ***expanding business offerings and geographic reach***, ***implementing lean construction concepts***, and embracing ***digital transformation***. The study by [12] explains that the extension of geographic reach allows an organisation to grow its market by targeting new clients while expanding business offerings allows a corporation to grow by offering new products and services. The economic growth will also increase due to the growth and success of the entire construction sector if the South African construction industry expands its business offerings and geographic reach. On the other hand, lean construction eliminates unnecessary value-adding processes, thus lowering waste production while improving overall project performance by reducing costs and speeding up project completion [13], and digital transformation involves adopting various digital technology to improve the effectiveness of traditional processes [14].

With this, BIM is an enabler of all these strategic initiatives. It offers the digital transformation strategy as outlined in Figure 2, it catalyses lean construction as outlined by [15], and it uses cloud computing which is effective for collaboration regardless of physical location [16], thus allowing the expansion of geographical reach. It also enables the growth of business offering through offering structural changes as well as creating the new required value path [2]. However, traditional asset information management is limited to all the required strategic initiatives. Hence, BIM implementation is essential in the construction industry.

Using BIM to achieve strategic initiatives for the South African construction industry will additionally help in the fulfilment of SDG 8, SDG 9, and SDG 12. The fulfilment of SDG 8 focuses on target 8.2 which favours increasing economic productivity through innovation, technical advancement, and sector-specific attention to high-value added and labour-intensive industries (in this case, the construction sector) [17], and target 8.1 may be accelerated by achieving target 8.2 since the economy of South Africa is immensely affected by the development of infrastructure as outlined by [18]. Target 8.1 entails sustaining economic growth per capita in accordance with national circumstances, particularly at least 7% GDP growth per annum in the least developed countries [17].

The link between target 8.2 and target 8.1 is through fulfilling SDG 9, particularly target 9.2 which entails fostering sustainable industrialisation, and significantly increasing the sector's employment and GDP share (construction sector) by 2030 as per the national conditions as well as doubling its share in the world's least developed countries [17]. Similarly, SDG 12 is satisfied by ensuring that chemicals and wastes throughout the lifecycle are reduced significantly in the environment in compliance with accepted international frameworks to minimise their drastic effects on human health and the environment, thus achieving target 12.4 [17].

2.2 Asset Information Management Processes and Outputs

The South African AM toolkit highlights the fact that asset information management starts with information and data collection which essentially involves ***data capture***. Data capture also includes ***standardising information*** to improve data consistency. As a result, ***information accuracy and standardisation*** are enabled by data capture and standardising information. The study by [1] outlines that asset information management generally involves the process of acquiring, ***organising*** and integrating asset data which requires ***effective collaboration***. Moreover, how ***information is stored*** affects factors not limited to ***information security***, ***data retrieval***, ***information accessibility and transparency***.

According to [19], the traditional strategy only allows for the transfer of data amongst the concerned parties while offering data in an unstructured form which results in unstandardised and inconsistent data that is difficult to manage. Instead, all stages of construction must replicate the data, and the data has no backups to be restored when using conventional means. Therefore, when reports are lost or damaged, information is not easily retrieved. This has an impact on information accessibility and availability, which are typically constrained by conventional techniques. Moreover, the unstandardised information as well as numerous files stored in different databases makes data organisation a challenge.

On the other hand, BIM has room for improving the asset information management processes and outputs. BIM can organise structured data from a single source of information, which facilitates better information availability and accessibility when needed [19]. It additionally enhances collaboration, thus allowing open and accurate stakeholder communication while fostering standardisation. Data visualisation provided by BIM enables clear pictures of project communications that improve the data capture process, unlike the traditional method. Moreover, the computer software used to store information is an enabler for information retrieval when data is lost. However, information security in BIM is reduced due to hacking opportunities and viruses, unlike traditional methods. With this, BIM generally improves information management in the construction industry.

2.3 Cost and Expenses

There are two types of IAM expenditures, namely capital expenditures ***(CAPEX)*** which involves expenses for new construction, upgrading, and renewal as well as disposal and operating expenses ***(OPEX)*** which considers only the operations and maintenance costs [5]. Each construction project has its stipulated budget known as ***project cost/ contract cost*** that can be direct or indirect. Moreover, projects are executed by skilled labourers who acquire their skills through training, and the ***training costs*** can be paid by the employee or the employer.

The CAPEX of BIM is increased by purchasing hardware and software needed to implement it whereas OPEX is increased by the employment of information managers who design, create and maintain BIM. However, the project cost is usually reduced by implementing BIM [2] due to several factors including a decrease in errors and faults, project delays, and material waste. Nowadays, people are also interested in equipping themselves with BIM expertise; hence the training costs for BIM employers are not too much since some employees pay for their training. Besides, adequate training is mandatory for any new employee so that they can easily adapt to how things are done in the organisation. With this, training costs must not hinder BIM implementation.

2.4 Quality

The ***completion of a project within the required budget***, ***time***, ***and scope***, as well as the ***satisfaction of all engaged stakeholders***, constitutes both project quality and project success [20] & [21]. With this, a project is considered successful with superior quality if it is completed within budget, schedule and scope while the stakeholders are satisfied with the outcome of the project. Moreover, ***sustainability*** as well as the protection of the environment is imperative in the construction industry since it consumes a significant amount of resources which have a large impact on the environment and ***construction healthy and safety*** of workers and the environment affected by the construction project must be considered as one of the aspects of sustainability [18]. The ***maintenance of built infrastructure*** also affects the sustainability of infrastructure. This is supported by the study by [15] that outlines infrastructure asset maintenance correctly promotes resource conservation, lowers energy consumption, improves the energy efficiency of operational buildings, and offers a safer and cleaner environment for people.

Similarly, ***adaption to complex projects*** affects project quality. The study by [14] states that *"our challenges are becoming more complex and more technical. What we build isn't simplistic anymore. We're beyond the point where the old mechanisms and the standard training are sufficient. The people involved are not able to correlate all the data in their heads without the assistance of systems. So, digitalisation is no longer an option."* The quote highlights that digitalisation which is enabled by BIM can help improve the adaption to complex projects. BIM also generally helps with other aspects of quality, like completing a project within the required budget, scope and time by reducing project cost and increasing productivity [2]; improving maintenance of built infrastructure in the operations and maintenance stages [15]; enhancing sustainability by supporting the overall concept of sustainable construction through delivering verifiable results and making a significant contribution to the three pillars of sustainability, namely social, economic, and technology aspects [22] & [22] further elaborates that BIM tools and technologies can be used to advance construction health and safety. All this directly affects the satisfaction of stakeholders. As a result, the chances of the stakeholders being happy with the outcome of the construction project increase.

Moreover, SDG 3, SDG 6, SDG 8, SDG 9, SDG 11, and SDG 12 will be fulfilled by implementing BIM in the construction industry. BIM can help achieve target 3.9 which requires the reduction of deaths by 2030 due to water, air and soil pollution that results in the production of dangerous chemicals. BIM helps in reducing carbon dioxide emissions [22], thus reducing air pollution and it reduces soil and water pollution by reducing the contaminants that are produced in the construction industry through catalysing lean construction [15]. This additionally drives the success of providing sustainable management of water and sanitation by fulfilling target 6.3 of improving water quality by reducing pollution and target 6.6 of protecting water environments. Consequently, adopting BIM generally creates opportunities to achieve SDG 8: decent work and economic growth; SDG 9: industry, innovation and infrastructure; SDG 11: sustainable cities and communities and SDG 12: responsible consumption and production through enhancing sustainability as well as health and safety. When these SDGs are achieved, they can additionally help fulfil other SDGs since they are interlinked. As a result, BIM can generally help enhance the quality of life, unlike the traditional method. However, BIM implementation also has issues which are merely political and legal, economic and technological and cultural and individual that affects its impact. The MCA will therefore help quantify the impacts of the identified criteria to explicitly compare the two methods.

3 METHODOLOGY

This paper uses a multicriteria analysis approach to evaluate the benefits of implementing Building Information Modelling (BIM) in the South African construction industry, and the technical guideline of the Australian government made by Infrastructure Australia that outlines the assessment framework of the multicriteria analysis is used as the guideline. The qualitative data are gathered from the Google Scholar database, while the quantitative data of the scores are facilitated by the scoring system shown in Figure 4. The criteria scores and their weights are based on simplicity and intuitiveness as suggested by [4], while the results from communicating with professionals on LinkedIn through a poll determine the weight of the objectives, and the outcome of the poll is in the appendix section. Using both methods enables the subjectivity brought by the qualitative approach to be compensated for by the objectivity of the quantitative analysis [23]. Moreover, the necessary steps taken to complete this study are summarised in Figure 5.

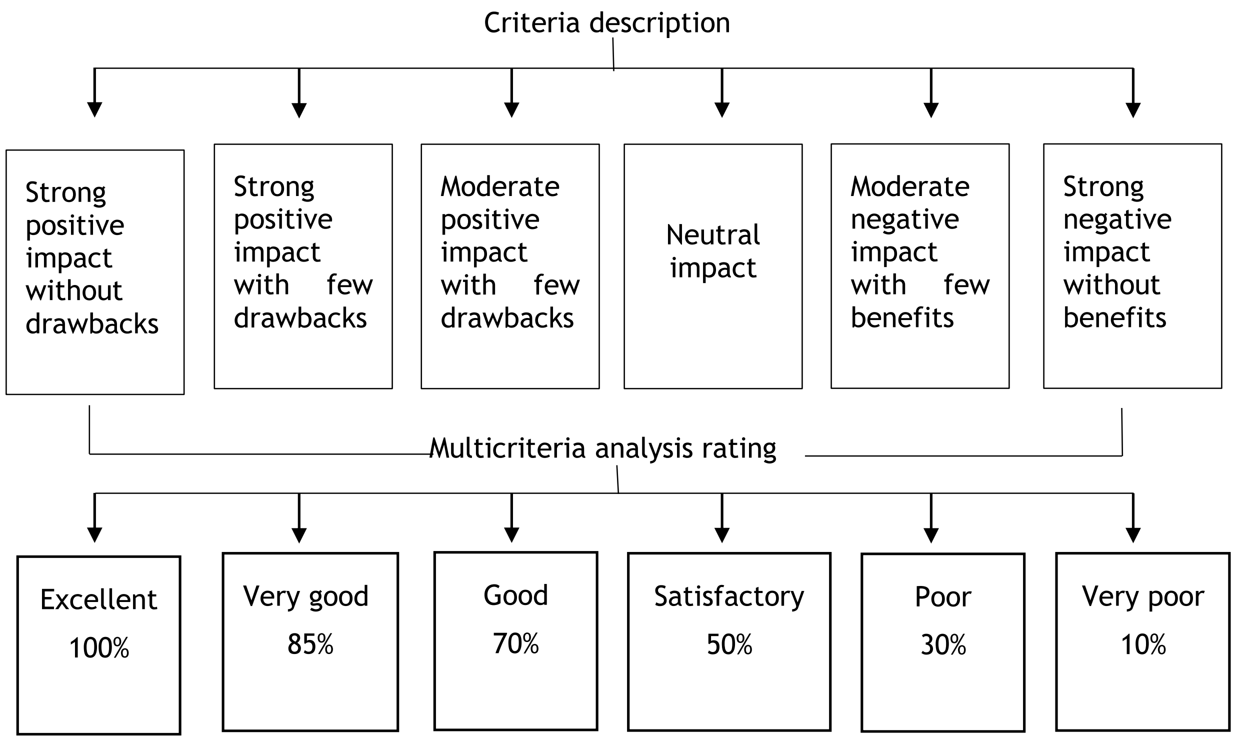

Figure 4: Proposed scoring system applied to multicriteria analysis.

Steps Taken	The Objective of the Step
1. Indentify the problem	To select the appropriate research approach
2. Develop key words	To identify relevant literature
3. Collect and analyse data	To understand the concept of BIM and asset information management
4. Develop the MCA	To compare the BIM and traditional approach of asset information management using Microsoft Excel tools

Figure 5: Flowchart of research methodology

The development of the MCA is done by initially identifying the objectives and the criteria using the literature study. Subsequently, the objectives' weights are determined, as well as the criteria scores and weights. Finally, the BIM and traditional approaches of asset information management are ranked using the MCA method outlined by the technical assessment framework of the multicriteria analysis guideline of the Australian government, as made by Infrastructure Australia.

4 RESULTS ANALYSIS

This section summarises the MCA results findings and provides a discussion of the statistical analysis for MCA outcomes. Table 2 provides an overview of the MCA scores, objectives, criteria and weights.

Table 2: The Multicriteria Analysis Matrix

Objectives and Criteria	Weights	Option Scores	
		Traditional Method (%)	*Digitalised (BIM) Method (%)*
Objective 1: Top Strategic Initiatives for SA construction industry	**0.1**	**20**	**92.5**
Criterion 1: Expansion of business offerings	0.1	30	85
Criterion 2: Expansion of geographic reach	0.1	30	85
Criterion 3: Implementation of Lean construction	0.3	30	85
Criterion 4: Digital transformation	0.5	10	100

Objective 2: Asset Information Management Processes	**0.2**	**40**	**71.5**
Criterion 5: Data capture	0.1	30	85
Criterion 6: Organising information	0.3	30	70
Criterion 7: Standardising information	0.1	30	70
Criterion 8: Effective sharing of information/ collaboration	0.3	50	70
Criterion 9: Information storage	0.2	50	70
Objective 3: Asset Information Management Outputs	**0.2**	**45**	**74**
Criterion 10: Information transparency	0.2	50	85
Criterion 11: Information accuracy and standardisation	0.2	30	85
Criterion 12: Information accessibility	0.2	30	85
Criterion 13: Information security	0.2	85	30
Criterion 14: Information retrieval	0.2	30	85
Objective 4: Cost and Expenses	**0.1**	**80**	**48.5**
Criterion 15: CAPEX	0.3	100	30
Criterion 16: OPEX	0.3	100	30
Criterion 17: Project cost/ Contract cost	0.3	50	85
Criterion 18: Training cost	0.1	50	50
Objective 5: Quality	**0.4**	**30**	**85**
Criterion 19: Stakeholders satisfaction	0.2	30	85
Criterion 20: Completion within required budget, scope and time	0.2	30	85
Criterion 21: Sustainability	0.2	30	85
Criterion 22: Maintenance of built infrastructure	0.1	30	85
Criterion 23: Adaption to complex projects	0.1	30	85
Criterion 24: Safety	0.2	30	85
Total Score		**215**	**371.5**

Total Weighted Average Score		**39**	**77.2**
Ranks		**2**	**1**

4.1 Statistical Analysis of MCA

This section transforms the multicriteria analysis into graphs which helps to check score variability and the trends of the multicriteria analysis. This helps deduce if the multicriteria analysis can be reliable or not. However, it must be noted that multicriteria analysis is a generally less reliable data decision-making tool. Despite that, multicriteria analysis can be successfully used to compare the AIM techniques with the influences of statistics. Figure 6 gives the score variabilities for the traditional and modernised techniques.

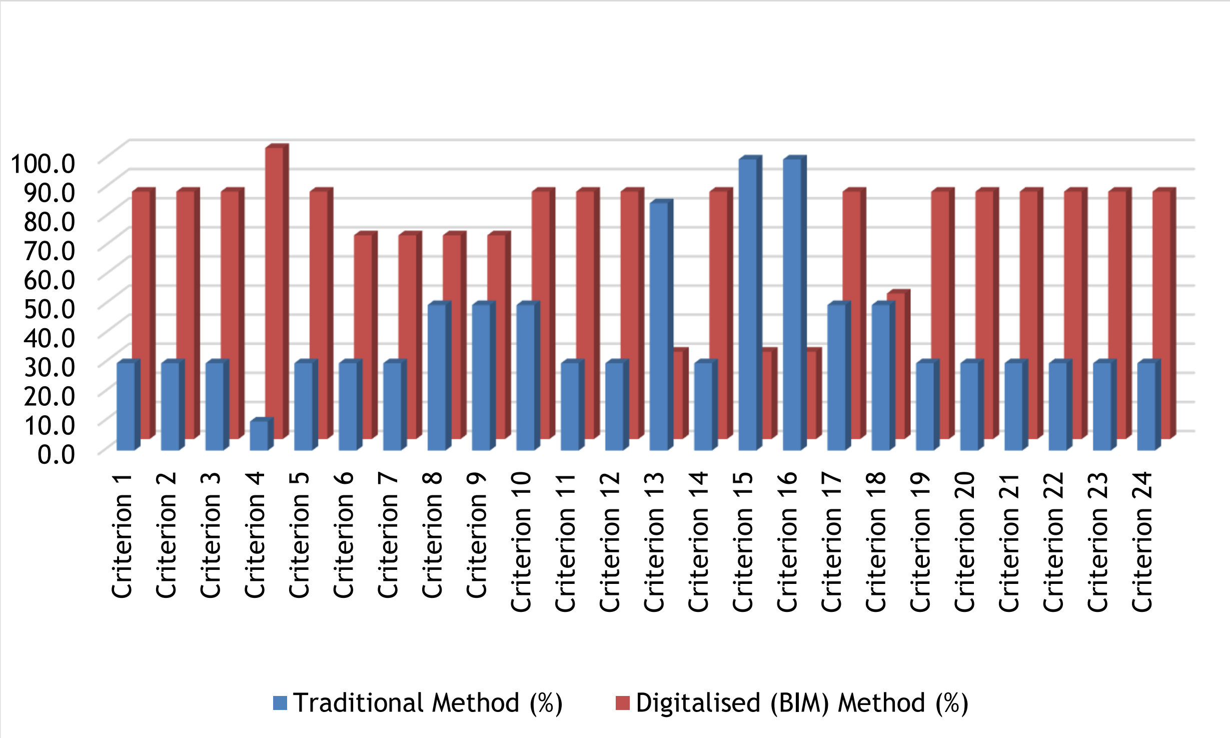

Figure 6: Score Variability of the MCA

In Figure 6, traditional method has wide-ranging values with a skewness of 1.7, a range of 90%, an average of 41.5% and a standard deviation of 22.9. The high range and standard deviation indicate that data is spread out around the mean. Moreover, the positive skewness shows that there are outliers that are distant from the mean on the right while they are closer to the mean on the left. The results show that there are three outliers, and the outliers are in criterion 13: information security, criterion 15: CAPEX and criterion 16: OPEX. The lower and upper outlier scores are 0 and 80, respectively where Q1 is 30 and Q3 is 50. This suggests that there may be errors in data collection of the multicriteria analysis due to factors not limited to human error, particularly inaccuracies in reasoning skills. Hence, it is imperative to check the percentage error of the weighted objectives to see whether these outliers are problematic or if they represent naturalism in the multicriteria analysis data.

On the other hand, the data of the digitalised (BIM) method in Figure 6 has a mean of 74.8%, a standard deviation of 19.7, a range of 70% and a skewness of -1.6. Just like the traditional technique data, the BIM data has spread out data around the mean due to the high range and standard deviation. On contrary, the modernised data has a negative skewness which indicates that there are outliers that are distant from the mean on the left while they are closer to the mean on the right. Similarly, the digitalised technique has three outliers in the same criteria i.e., criteria 13, 15 and 16. The lower and upper outlier scores are 47.5 and 107.5, respectively where Q1 is 70 and Q3 is 85. This shows that the percentage error of the weighted objective 3: Asset Information Management Outputs and Objective 4: Cost and Expenses are crucial since criteria 13 is for objective 3 whereas criteria 15 and 16 are for objective 4. The percentage error will help analyse the closeness of the measured value to an actual value and outline a comprehensive error analysis.

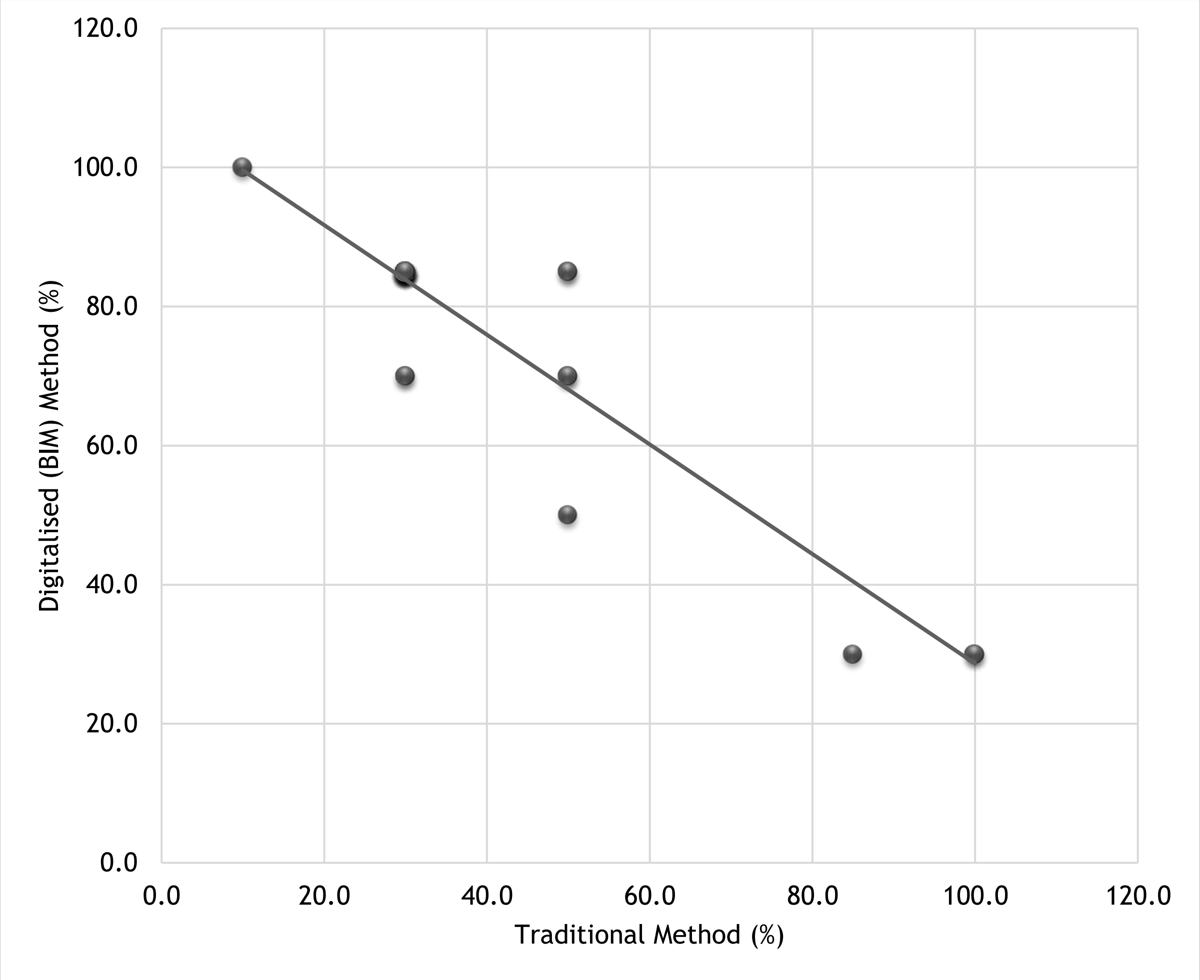

Figure 7: Correlation Graph

The multicriteria data analysis shows a strong correlation between the digitalised BIM method and the traditional method. Figure 7 shows the correlation graph between the two techniques. The correlation coefficient of the two AIM practices is -0.9. This is a high number, which emphasises the high correlation. The negative sign indicates that the more you implement the digitalised BIM method to manage asset information, the less you implement the traditional method or vice versa. The results show that there is no effective implementation of the traditional method and digitalised BIM technique simultaneously. This is in line with what is expected in the real world because BIM is believed to be a disruptive innovation, which significantly changes how the construction industry operates. Hence, the South African construction industry needs to understand that if it is to implement BIM innovation, information regarding how to transition from the traditional method to digitalised practices, such as the frameworks and the guidelines for BIM information models, is crucial. The frameworks and guidelines that South Africa may create to help their construction industry adopt BIM must also consider the challenges that arise with adopting BIM as well as how they can be resolved so that a smooth digital transformation may be promoted.

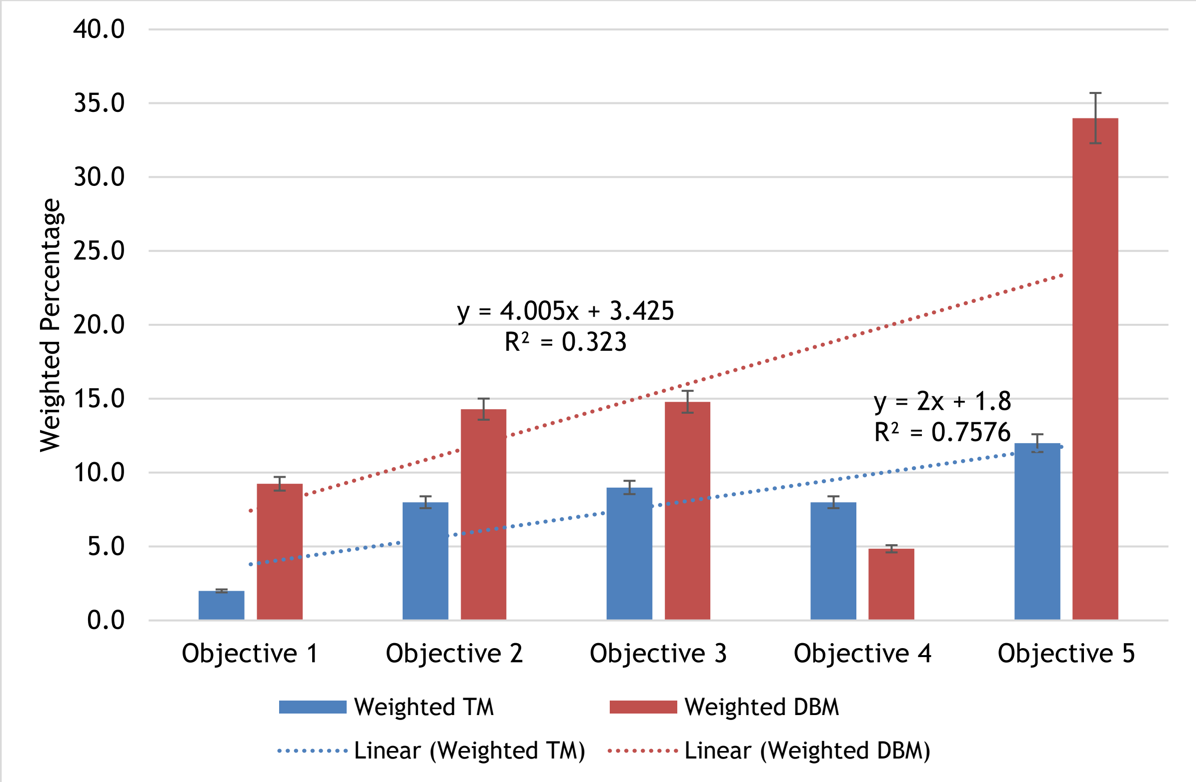

Figure 8: Traditional Method VS Digitalised BIM Method for Objective Weighted Average Score

The comparison of the weighted objectives of the traditional method and the modernised technique is shown in Figure 8. Accurate information is essential when managing data, and the IIMM recommends a 5% data accuracy review as a quality assurance measure [5]. Hence, the acceptable percentage error of the weighted objectives must be in the range of ±5%. As mentioned earlier, the percentage error, particularly for objectives 3 and 4 are crucial in deducing whether the outliers are problematic or not. The percentage errors for all the weighted objectives are generally in the range of ±5% in Figure 8. It can therefore be deduced that the three outliers identified in the multicriteria analysis do not highlight the inaccuracies of data collection. Instead, they illustrate the naturalism of the collected data.

The graph in Figure 8 shows that the multicriteria analysis model framework fits the collected data because the R^2 values are between 0.3 and 0.7 [24]. However, the multicriteria analysis model fits the weighted objectives of the traditional method (R^2=0.7576) more than those of the digitalised BIM method (R^2=0.323). This explains the generally lower percentage of errors in the traditional method than in the digitalised BIM method. The trendline equations also suggest that for any variable of x, the digitalised BIM method results will always be approximately double those of the traditional method. Additionally, this cements the fact that the implementation of BIM in the South African construction industry can lead to significant improvements in asset information management. The multicriteria analysis conducted in the study found that the BIM method consistently outperformed the traditional method in terms of the identified criteria, including the expansion of business offerings, and the expansion of geographic reach as the top strategic initiatives for the South African construction industry. The study concludes that the methods used to manage assets need to be modernized in the South African construction industry, and that BIM can produce approximately double the results of the traditional method for any variable of x. However, more research is required to confirm the trend and relationship shown in Figure 8.

Moreover, the radar chart in Figure 9 shows that the BIM method is generally better than the traditional method in all objectives excluding Objective 4: Cost and Expenses. This is due to the high initial cost of purchasing BIM hardware and software as well as the operational costs associated with managing and operating BIM. However, these are short-term disadvantages, and in the long-term, the company benefits more by improving project delivery and productivity through adopting BIM, thus increasing their profit margins.

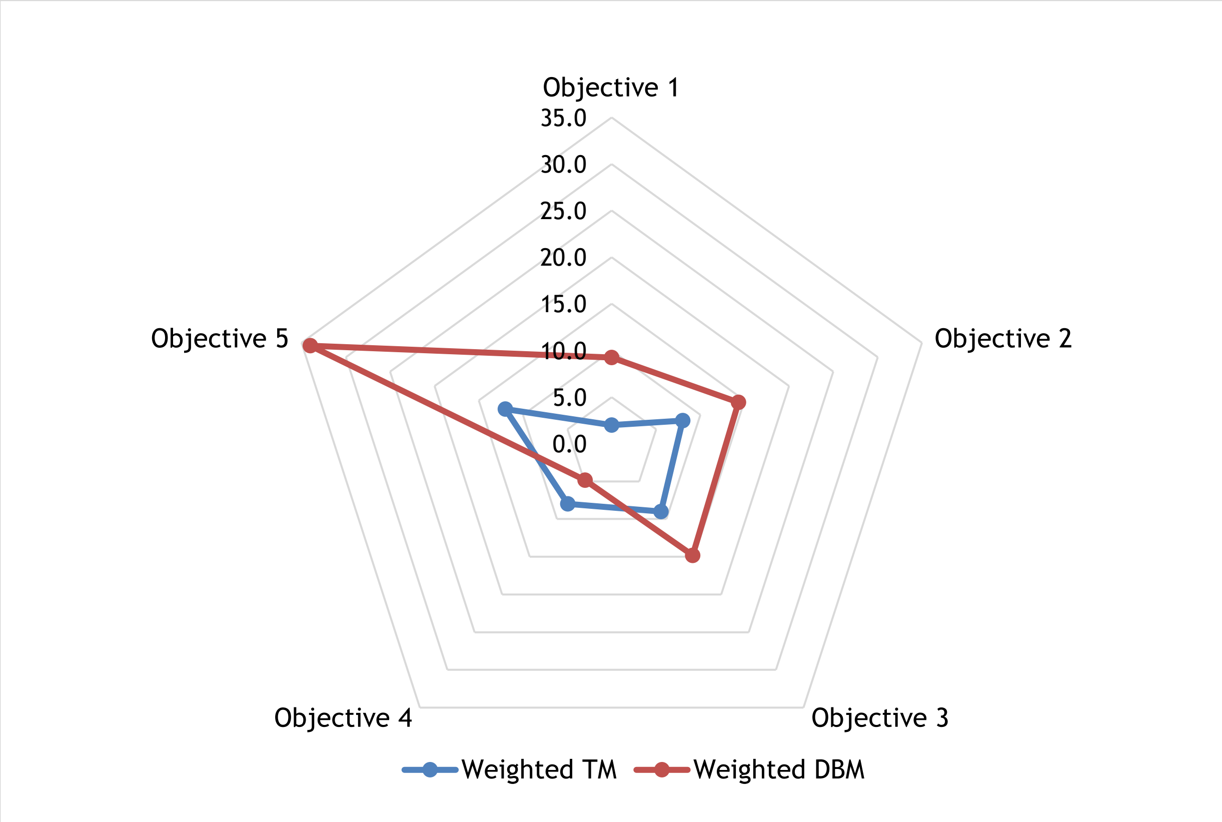

Figure 9: The Radar Chart of the MCA

5 CONCLUSION

It can be concluded that the results of the multicriteria analysis can be accepted because they show naturalism, the skewness of the graphs is within a range of ±3, the percentage error of the weighted objectives is within a range of ±5%, the multicriteria analysis model structure fits the data well and there are significant relationships that have been recognised by the multicriteria analysis. As a result, it is evident that the methods used to manage assets need to be modernised in the South African construction industry since the BIM technique will always produce approximately double the results of the traditional method for any variable of x. Moreover, the multicriteria analysis is not biased, or if there is any, the bias is insignificant, as the sample results, i.e., the multicriteria analysis results represent what is expected in the population, namely, the construction industry. The high standard deviations and ranges of data are in line with the theory that the multicriteria analysis is generally a less reliable decision-making tool. However, in this case, the results may be trusted and reliable due to acceptable accuracy and insignificant bias. Hence, BIM is the future of asset information management in South Africa, as per the MCA results of this paper.

ABSTRACT

To explore the common System Dynamics (SD) research approaches applied to solve the engineering problems. The outcome shall be used in the development of Dust and Ash plant maintenance SD model. SD studies were identified from 1981 to 2022. This was done through systematic literature review research methodology and Thematic Analysis Framework. These studies (21) were reviewed for the type of research problems, report structure, frameworks applied, instruments used to build the model, type of publication, trends and SD software used. Studies (70%) made use of Forrester SD research framework. Theoretical framework was found to be vital for the prediction and explanation of the plant maintenance phenomenon. Studies (42%) made use of mixed research instruments and interviews were common in all studies. Five different types of software were identified and Vensim SD (50%) was the most common. These learnings shall be applied in development of SD model in the future.

Keywords: System dynamics, Data, Dust and Ash plant and Studies.

1 INTRODUCTION

System Dynamics (SD) is a suitable approach for modelling homogenous systems, which is described by interactions among variables and their feedback structure at an aggregate level [1] while Agent-based (AB) approach allows all individual building blocks to carry their individual characteristics. In this study, system dynamics approaches used to solve a wide variety of the industrial problems shall be explored with the objective to extend the learnings to dust and ash handling plant maintenance problem.

Sterman [2] argues that the behaviour of a system arises from its structure and Amen ([3] and [4]) who is practicing psychiatry argues that behaviour is an expression of a problem and not a problem. Amen makes use of single-photon emission computed tomography (SPECT) to identify loop that is accountable for the behaviour while Sterman makes use of the Systems Dynamics computer tool. These two academics are miles apart, but their arguments are in harmony. Martin [5] reasons that the underlying relationships and connections between the components of the system is called the structure of the system. Full understanding can only come when one dives beneath the plant maintenance behaviour to understand the structure causing the behaviour. Below in figure 1 is some of the common modes of behaviour in a dynamic system.

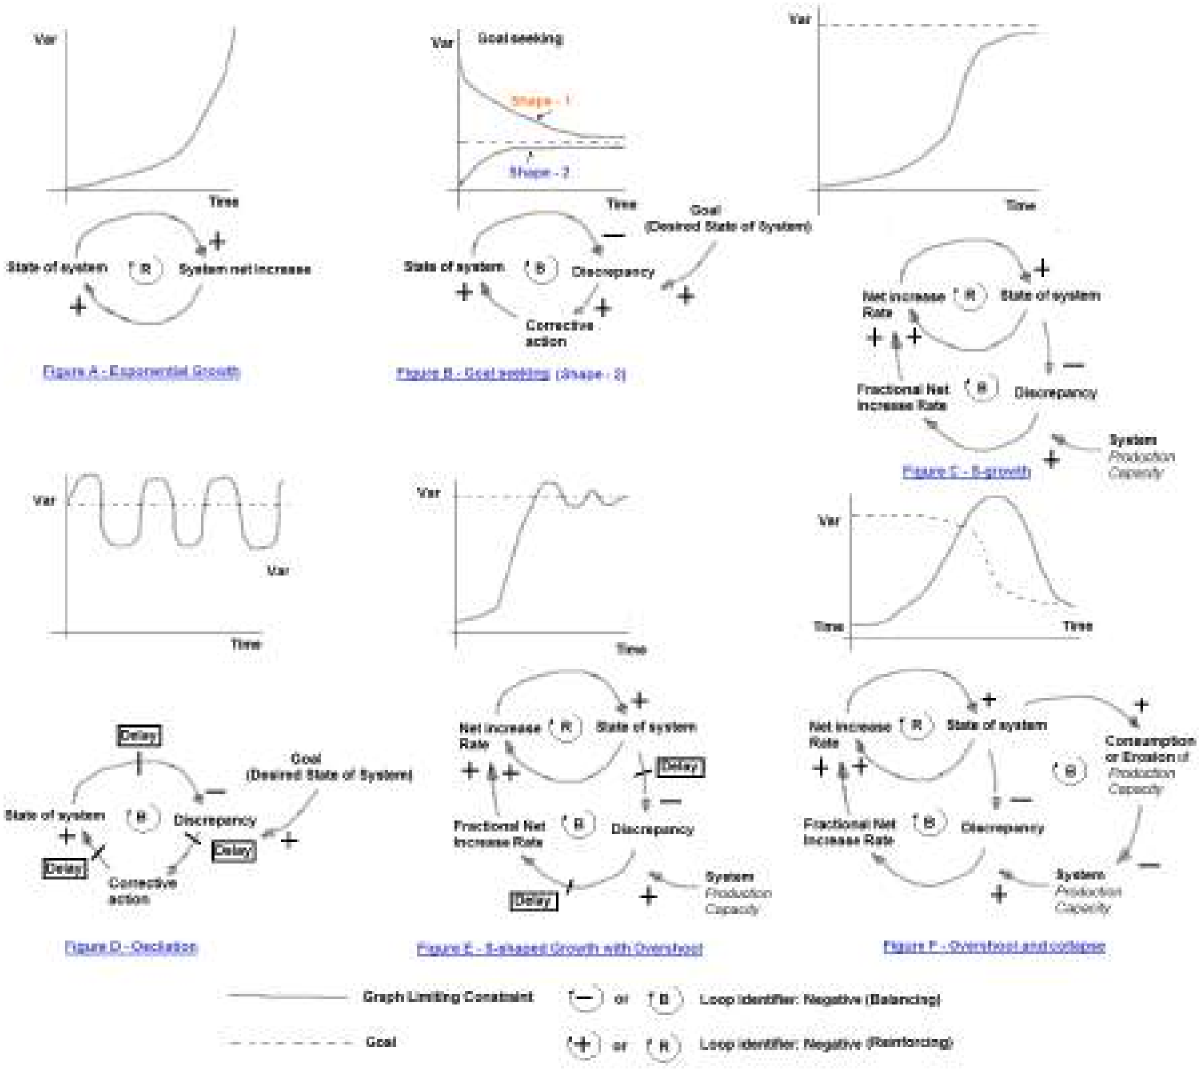

Figure 1: The common modes of behaviour in a dynamic system, Source: [2]

According to Sterman [2] "*growth, goal seeking, oscillation and their combinations are not the only behaviours that dynamic systems express. He argues that (1) Statis or equilibrium: state of the system remains constant over time, (2) Randomness - Sterman cautions the system dynamics student not to assign randomness when they cannot characterise the system behaviour and (3) Chaos.*" these form part of the common modes of the system behaviour in a dynamic system. He argues that individual components in a maintenance system do not contain the most complex behaviours, but the interactions of the components contain the most complex behaviours. Systematic Literature Review (SLR) will be done on the system dynamics topic with the objective understand the model building steps and attributes that define best SD model. The above-mentioned complex behaviours form part of what the future system dynamics maintenance model will attempt to unravel in the future.

2 RESEARCH OBJECTIVE

The researcher was tasked to improve the health of the dust and ash plant in a coal-fired power plant and a need was to learn from the work of the researchers who have travelled this route of solving problems using system dynamics approach. The study is based on the work conducted by various researchers dating 1981 to 2022. Therefore, the objective of the study is:

- To establish as to how system dynamics tool was applied using systematic literature review methodology.
- To present a summary of the implications of the systematic literature review findings for industry practitioners, researchers, and policymakers, offering insights into the potential benefits and challenges associated with the application of System Dynamics.

These best attributes obtained in these studies will be transferred to the future SD maintenance model.

3 RESEARCH QUESTIONS

Based on the stated background, systematic research methodology has been adopted to learn from the system dynamic research that had been conducted in the past. This study seeks to answer the following question:

- How to apply system dynamics methodology so that the dust and ash plant poor performance can be enhanced?

In addition to tackling this question, the study shall characterise the studies (21) by paying attention on the following themes: *Report structure, Software applied, Type of problems tackled, Types of data sources used to build model, Type of publications and Theoretical Research Frameworks* that was adopted by the researchers in the studies. The outcome of this study shall be used to aid the authors to build the dust and ash plant system dynamic model with the objective to enhance plant uptime.

4 RESEARCH METHODOLOGY

A systematic literature review (SLR) methodology was adopted, google scholar was indexed on the 28th of April 2023 to extract relevant journals, conference papers, theses and books that were applicable for system dynamics problems. Then, data was coded and extracted from the manually and included studies to synthesize and appraise the results, describe how the system dynamics was applied in practice, and highlight any gaps or discrepancies. Total of about 21 system dynamics articles were mapped in this study. The investigation process made use of explicit and replicable search strategy, studies were excluded or included, based on the inclusion criteria.

The benefits and shortfalls of this methodology were known; hence research controls were put in place to eliminate bias. The ability of this study was to explore a number of system dynamics cases from various socio-cultural contexts and present a holistic view as its main strength. There were several restrictions to be aware of in addition to its strength, researchers provided country-specific cases that were subject to their own interpretation and may be subjective [6].

5 SEARCH STRATEGY AND SELECTION PROCEDURE

Modified Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) systematic review principles [7] have been used for assessing and reporting the system dynamics studies to identify the best practices of SD applications. The research methodology that was followed is represented in figure 1 below. The authors made use of PRISMA 2020 for abstracts checklist and in cases where the abstract was not comprehensive, the authors had to review the entire article so that value could be extracted from the selected papers. The search engine made use the following search string: *application of system dynamics*. Due to lack of structured research in the system dynamics application, it was burdensome to select the appropriate search words, total of 40 articles were identified for the systematic review, to select the final articles to be included in this review, a practical screening was conducted, this was based on the setting of inclusion criteria.

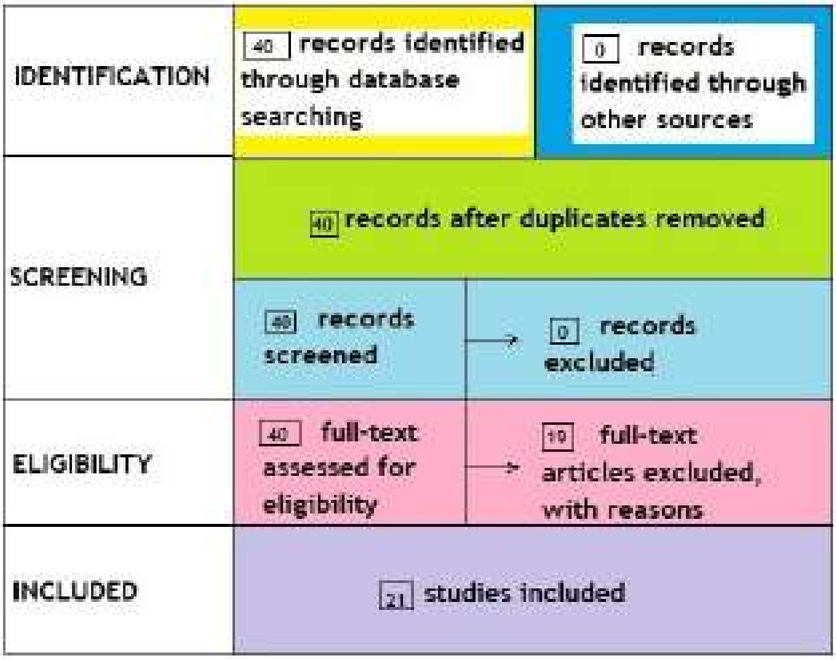

Figure 2: Systematic review flow diagram. Source: Adapted from [7].

6 INCLUSION CRITERIA

The initial search yielded 40 records through general internet search and manually. Total of 19 studies were removed for other reasons, leaving 21 studies that were then screened, applying the inclusion/exclusion criteria (see figure 2). Only English studies were selected (Table 1). Studies were included if they were published between 1981 and 2022. This included 21 journal articles, theses and conference papers. This process was followed to assist the peer-reviewers to able to easily establish the replicability of this study for confidence building in the research outcomes. The studies covered system dynamic models that were applied in the general industry.

Table 1: Inclusion criteria

Item	Description
Database searched	Google scholar and manual search
Date of search	28 April 2023
Person searching	Sello David Koloane
Database settings	Open to all areas that had researched about system dynamics application in the general industry
Language	English
Timespan	1981-2022
No. of records obtained	40
Search string	"system dynamics application"
Questions	**Review focus**
Population – who?	System Dynamics application models locally and internationally.
Intervention – what?	System Dynamics application models that had been duly developed and tested so that the learning could be transferred to dust and ash plant uptime enhancement project.
Comparator/s – compared to?	Best system dynamic plant model with high availability internationally.
Outcomes – expected result	Identification of the system dynamics model levers that can be explored and transferred to the dust and ash plant model for an enhanced plant uptime.
Time – when?	1981-2022
Setting – where?	In the power plant and general industry setup

7 STUDIES SELECTION

A total of 40 relevant papers in all were found in Google Scholar at first. But after looking at the titles and the abstracts, it was discovered that 19 of these publications largely dealt with systematic literature and did not clearly highlight the application of system dynamics. To assess the use of system dynamics in general industry, a detailed analysis of the remaining 21 articles was conducted. These articles were distributed over 21 various theses, journals, and conferences. Most of them were published in fourteen theses from different universities across the world.

Using the qualitative data analysis, all articles that had met the requirements were examined and coded [8]. Thematic analysis, according to [9], "is a method for identifying, analysing, and reporting patterns (themes) with data." *SD report structure, SD Software applied, Type of problems tackled, Type of publication, Types of data sources used to build model, Type of publications and Theoretical Research Frameworks* used were the themes that were adopted. This was the culmination of a six-step procedure, as seen in figure 3 below.

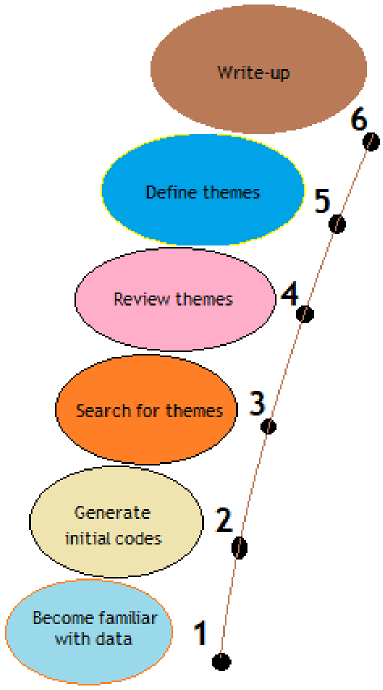

Figure 3: Framework for doing thematic analysis. Source: Adapted from [8,9] and [10].

The results of the thematic analysis have been captured under appendix A ([27] to [48]). During the application of the research methodology, it became evident that the studies were not well structured as abstracts could not be used to obtain all thematic data required to prepare for the building of dust and ash plant SD model, for this reason and others, meta-analysis could not be applied as the SD studies were heterogeneous and did not meet PRISMA guidelines requirements.

8 STUDY CHARACTERISTICS

8.1 TYPE OF RESEARCH PROBLEMS

Majority (29%) of the problems that were under review came from the energy related sectors, this was followed by the project management type (19%). The study has also revealed that application of system dynamics covered wide spectrum of studies as ten different fields were covered. These included: Water management, Supply chain, Quality, Manufacturing, Maintenance, Sustainability, Technology Change Management and Scheduling. Forrester [11] reasoned "*that our social systems are far more complex and harder to understand than our technological systems. Why, then, do we not use the same approach of making models of social systems and conducting laboratory experiments on those models before we try new laws and government programs in real life?*". Application of this tool in these diverse sectors has confirmed the visionary work of SD founding father.

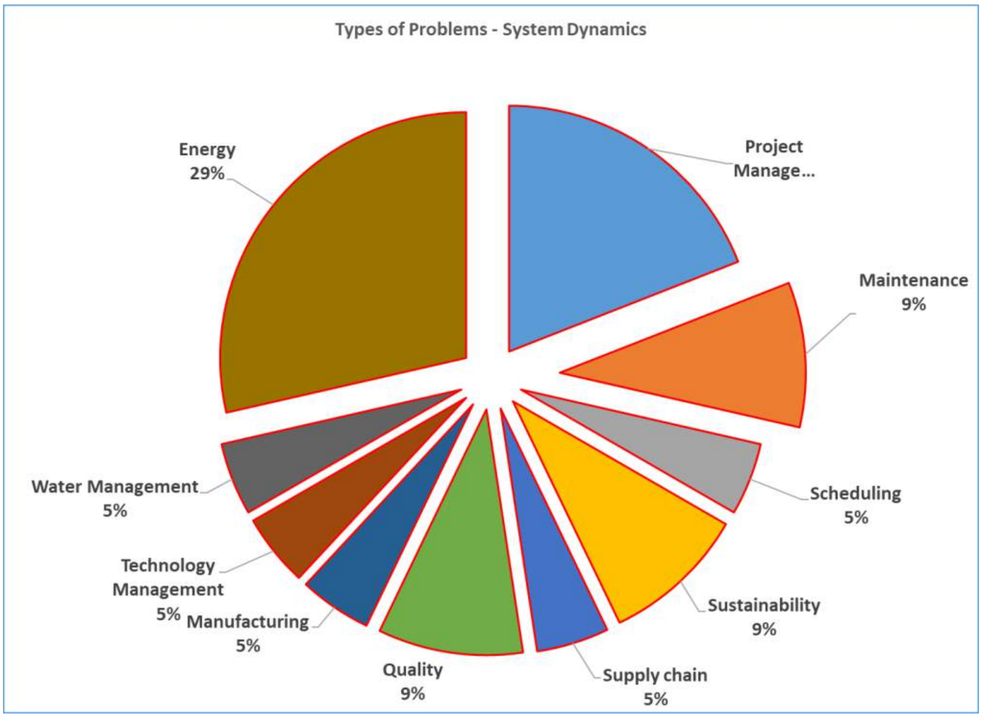

Figure 4: Types of problems solved using system dynamics modelling.

8.2 PUBLICATION REPORT STRUCTURE

Most of the literature that was reviewed had five sections (38%). Eleven of the Ph. D theses had structure divided into eight sections (24%). The least number of sections in SD report was four while the highest was nine. The study has also revealed that SD lacked systematic tool to aid the researchers to report SD modelling results uniformly across the fields to eliminate replication crisis.

Table 2: Types of problems solved using system dynamic modelling.

Publication Type	Four Sections	Five Sections	Six Sections	Seven Sections	Eight Sections	Nine Sections	TOTAL	Type of Publication Contribution
M.Eng Thesis	0	3	0	0	0	0	3	14%
PhD Thesis	0	2	2	1	5	1	11	52%
Licentiate Thesis	0	1	0	0	0	0	1	5%
Journal	1	2	0	2	0	0	5	24%
Conference	0	0	0	1	0	0	1	5%
TOTAL	1	8	2	4	5	1	21	TOTAL
Publications with X sections	5%	38%	10%	19%	24%	5%		

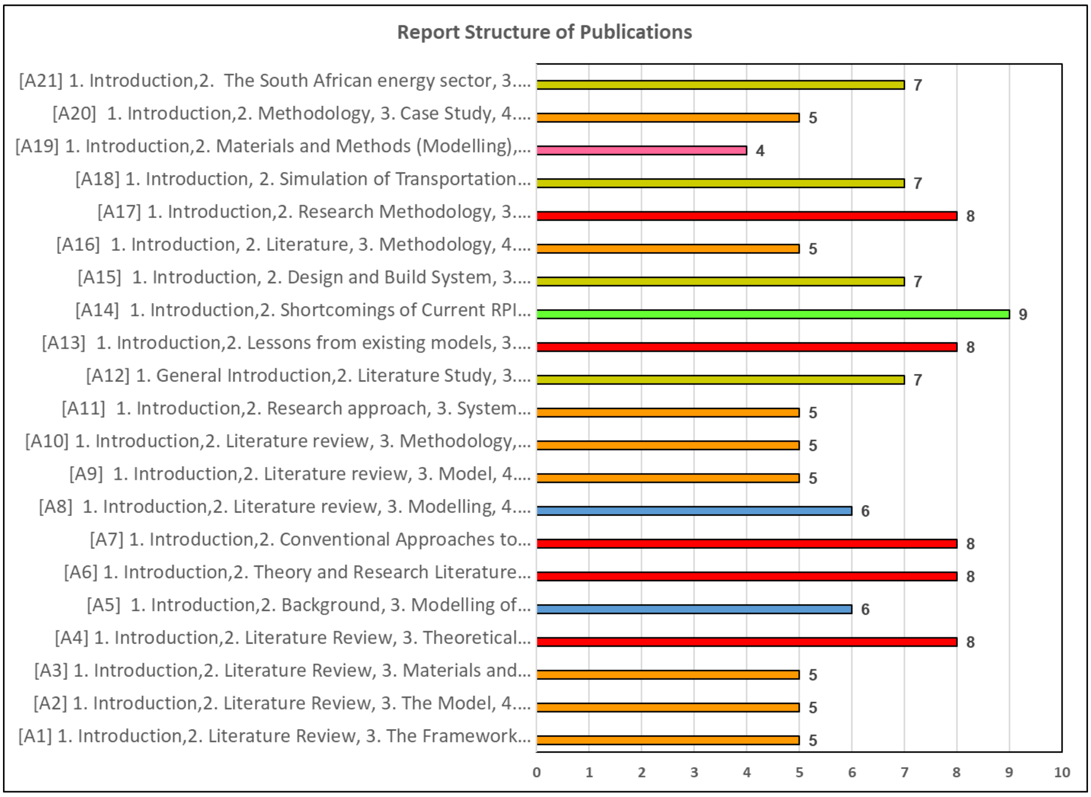

Figure 5: Study - Number sections in the SD report structure.

8.3 RESEARCH FRAMEWORKS APPLIED

Scientific inquiry objective is to find an explanation and prediction about the world of dust and ash system in a coal-fired power plant, to achieve this enlightenment; scientific methods must be applied with rigour so that theory can be developed to provide phenomenon's description and prediction. Popper [12] sums up the criterion for the theory's scientific status as its falsifiability, or refutability, or testability. Glassman [13] argues that a theory is a hypothesis with at least one non-trivial validating datum while Glanz, Rimer and Glanz *et al*. [14] defines theory as a set of interrelated concepts, definitions, and propositions that present a systematic view of events or situations by specifying relations among variables, in order to explain and predict the events or situations. Table 3 below provides more insight based on the work of the various researchers.

Table 3: Theory definitions

Definition	Source
Theory is an organized body of concepts and principles intended to explain a particular phenomenon.	Leedy and Ormrod [15]
A scientific theory is a set of statements that, when taken together, attempt to explain a broad class of related phenomena.	Eastwell [16]
Theory has four components: Definitions, domain, relationships, and predictive claims to answer the natural language questions of who, what, when, where, how, why, should, could and would.	Wacker [17]

The most applied theory in the systematic literature study that was reviewed is systems thinking theory which is the foundation of the system dynamics founded by Forrester. Boulding

[18] argues that periodic table that was discovered by Dmitri Mendeleev in 1869 can be used to support the general system theory. Development of the periodic table was able to indicate to the scientists that certain *elements existed* and were *unknown* and this opened a room to search for these missing elements [19]. Systems theory also seeks to serve as a periodic table in the republic of engineering to identify and predict the missing theories so that the body of knowledge can be enhanced.

Arnold and Wade [20] critically examined various definitions offered by different experts and based on the strength and weaknesses that they had identified, they developed a new definition: "*System thinking is a set of synergistic analytic skills used to improve the capability of identifying and understanding systems, predicting their behaviours, and devising modifications to them in order to produce desired effects*". The same definition shall be applied to explore the Dust and Ash plant performance to understand the system dynamics involved, predict the plant behaviour in order to drive the plant availability to the highest level.

This plant is complex as it contains numerous items, different types of technologies, operated by different people, maintained by different people, processing different types of ash and so on. These parts have a complex intra- and inter-relationship structure with the performance of the whole plant as the cause and effect are not close in time and space [20]. Systems theory is vital for this research owing to the interaction and interdependencies that exist within Dust and Ash plant.

Kivunja [21] argues that a theoretical framework is made up of the theories put forth by experts in the system dynamics, which the researcher draw from to give a theoretical framework for your data analysis and result interpretation. Articles (21) studied made use of general system dynamics theoretical framework without describing the theoretical coat [21] that had been adopted while 57 % the articles had a section in their publication that was dedicated to the description of the theoretical framework. Below in Table 4 is a list of the frameworks that were used by the various researchers in this study.

Table 4: System dynamics - theoretical frameworks applied in the studies

ID	Theoretical Framework Applied
A1	System dynamics in general
A2	System dynamics in general
A3	Grounded theory, Narrative enquiry (interviews, observation and evidence from literature) and System Dynamics
A4	Theory of project management, Complexity aspect in the Project Management Research, Interaction of Risks in Mega Projects (STEEP) and System Dynamics
A5	System dynamics in general
A6	System dynamics in general
A7	Social-Ecological System Framework (SESF). Complex and Systems Thinking Theory
A8	System dynamics in general
A9	System dynamics in general

ID	Theoretical Framework Applied
A10	System Dynamics and Participatory Action Research - SyDPAR approach is a modelling process design resulting from the integration SD and PAR. Technology driven theory for guiding SD model building and validation (critical rationalist theory of science), and organizational decision choice theory for guiding decision making on HE quality issues (Garbage Can Model of Organizational Choice).
A11	Theory of Structure, Project management, Complexity aspect in the Project Management Research, Interaction of Risks in Mega Projects (STEEP) and System Dynamics
A12	System dynamics in general
A13	System dynamics in general. This is based on explicit causal theory of the economic behaviour. Behavioural theory of the decision-making at the microeconomic level.
A14	Systems theory, Complexity theory and Decision Theory. Group model-building (GMB), Dynamic Synthesis Methodology.
A15	Agent-based Model -System Dynamics-Building Information Modelling (AFM-SD-BIM) framework and Theory of Reasoned Action (ToRA).
A16	System dynamics in general
A17	Top-to-bottom-to-top dynamic systems modelling method (DSM) - Dynamic Synthesis Methodology Research Design. System Dynamics.
A18	The hybrid modelling framework - System dynamics (SD) and agent-based (AB) modelling. Mathematical modelling of agents - Interlinked modules for studying the diffusion of AFVs (Alternative Fuel Vehicles).
A19	System dynamics in general
A20	System dynamics-multiple objective optimization (SD-MOO) model-based water supply and demand prediction, dynamic adjustment, and water optimal allocation.
A21	Threshold 21 model - planning tool that integrates the economic, social, and environmental dimensions of a country into a single, comprehensive, transparent, user-friendly analytical framework. This is a system dynamic macro-model, based on the systems thinking approach.

Combination of the various theoretical frameworks that were applied by various researchers listed in the above table shall be applied through system dynamics tool to untangle plant maintenance problem that has dynamic combinatorial complexity.

8.4 RESEARCH INSTRUMENTS USED TO BUILD SYSTEM DYNAMICS MODEL

System dynamics methodology that was developed by Forrester [22] to solve complex feedback systems is explored by delving into the research instruments that were applied in the field. This methodology was originally designed to close the gap between real world observations (i.e., cause-effect relationship) by the users of the system and the policies that have been implemented to achieve certain outcome.

This methodology makes use of both qualitative and quantitative methods to build the system dynamic model. Qualitative approach is used to articulate problem statement, causal loop diagram and development dynamic hypothesis. Quantitative approach is used to formulate the simulation model using the stocks, flows, variables, etc. In solving these complex problems, the following sources of data are vital in the development of the model ([22] and [23]). Sterman [23] provided categories of the data sources that were essential in building the system dynamic model.

Table 5: Sources of data for modelling process. Source: [23]

Type of data source (s)	Description
Mental data (Most valuable for modelling process)	Information in people's mental models, such as their impressions, tales they tell, their understanding of the system and how decisions are made in practice versus how decisions are made in theory, how exceptions are handled, and so on. Interviews, observations, focus groups, Delphi methods and other methods are used to gather information.
Written data (Valuable for modelling process)	Records include operating instructions, organizational charts, media reports, e-mails, and other archival items.
Numerical data (Least valuable for modelling process)	Time series and cross-sectional records in various databases (E.g.: SAP PM maintenance data, etc.).

In this systematic literature review study, it was found that archival data (25%) was the most used research instrument, and this was in contradiction with the Sterman and Forrester's findings [24]. Group modelling with experts, observations and individual interviews constituted 42%. This finding agreed with established system dynamic methodology.

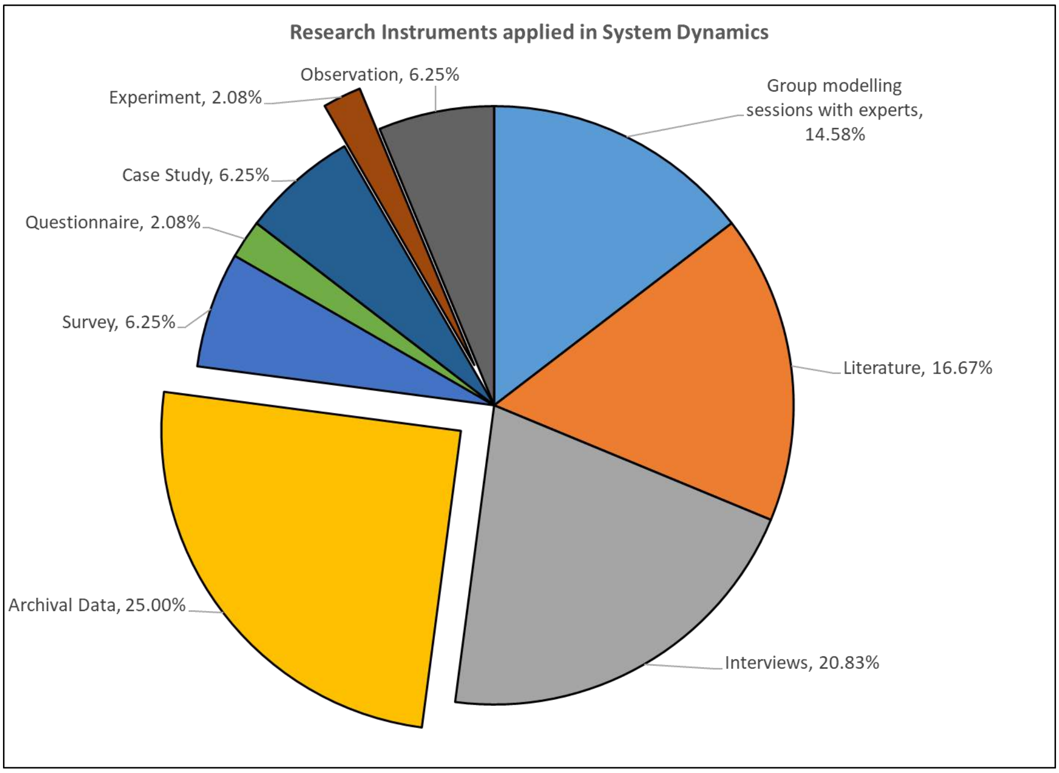

Figure 6: Research instruments applied in the System Dynamics studies

8.5 System Dynamics SOFTWARE applied in the studies

Most of the researchers (50%) made use of the Vensim software in the 21 studies that were reviewed. One study did not indicate the software that was used in study.

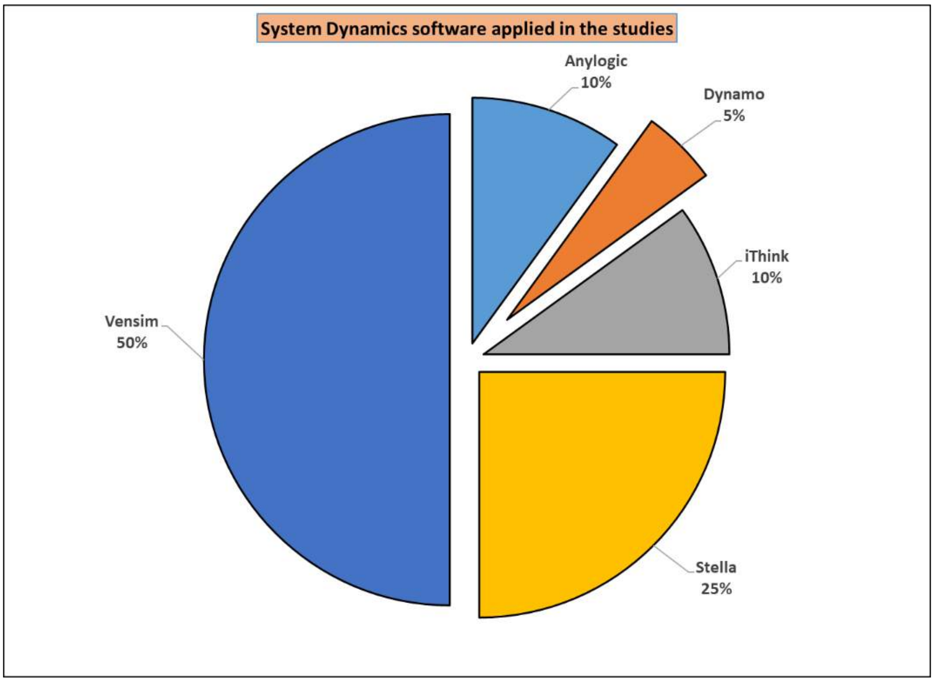

Figure 7: Software that was applied in the studies

According to the study conducted by [25], system dynamics software must be evaluated according to the following:

- Its foundation in the fundamental theory of system dynamics.
- Its usability.
- Support it provides for model development.
- The extent to which models can be documented and explained to the sponsor.
- Facilities it has for model debugging.
- The range of its facilities for designing policies.
- The ease of conducting trials and providing results.

Below in figure 8 is the evolution of the System Dynamics software.

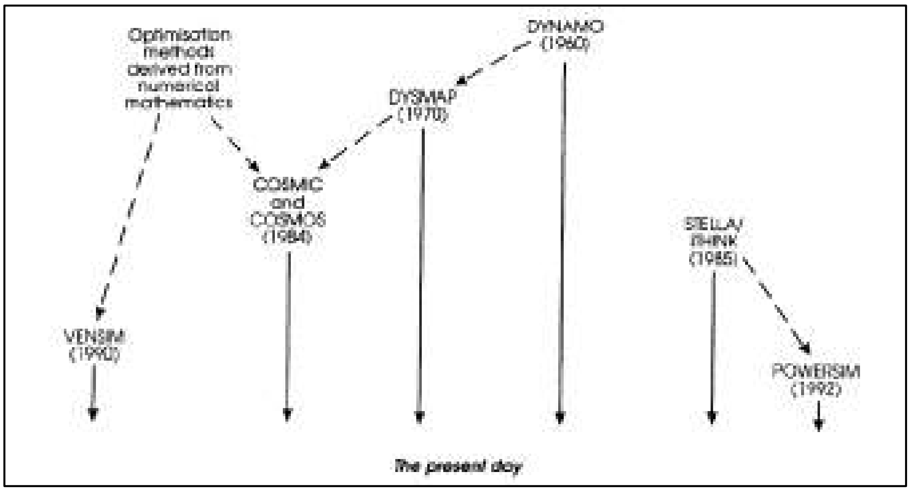

Figure 8: Evolutionary lines of system dynamics software, Source: [25]

8.6 PUBLICATION YEAR

The studies that were selected for the system literature review ranged from 1981-2022 and most of the studies were in 2016. Publications in these studies had stagnated.

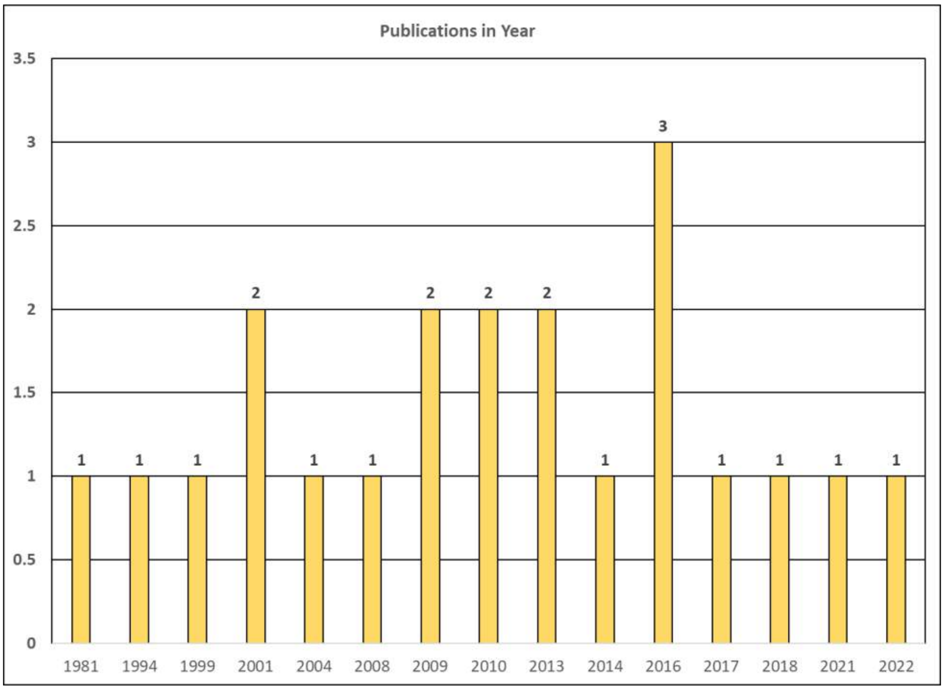

Figure 9: Publications in a year

9 DISCUSSION OF THE RESULTS

Table 6 below provide a summary of the systematic literature review and learnings that are important for the system dynamics practitioners.

Table 6: Summary of the SLR and learnings.

Item	Study Findings	Notes for the System Dynamics model practitioners
Type of research problems	System dynamics tool has been applied in different sectors (10) and energy sector was the leader. Forrester's prediction about the diverse application of this tool has been validated through the SLR outcomes. This was like the work done by Mendeleev regarding the periodic table elements that were yet to be discovered. System dynamics has the potential to predict the missing body of knowledge in the dust and ash plant dynamics. The two scientists' arguments were based on system theory. Amen's work in psychiatry and Sterman's work in engineering have recently produced the same results even though they from came two opposite positions - structure of the system defines its behaviour.	System dynamics is an ideal tool to identify and predict the missing body of knowledge in diverse fields and this has been validated as a good device to study the dust and ash plant problems for safer and higher plant uptime.
Publication report structure	Most of the SD publications (38%) had five (5) sections structure which included: 1. Introduction, 2. Literature Review, 3. The Model, 4. Simulation and Application of Results 5. Conclusion Ph.D. theses (52%) had minimum of eight (8) sections. SD publication structure was important to capture all crucial building block of the research. These blocks will aid in the validation by the peers.	SD publication must have a minimum of five (5) sections to cover all pertinent phases of the research while Ph.D. theses must have a minimum of eight sections.

Item	Study Findings	Notes for the System Dynamics model practitioners
Research frameworks applied	The most applied theory in the studies that were reviewed is systems thinking theory (57%). Application of this theory demands that the student of SD tool must study pertinent facets (people, tools, methods, technology, etc.) of the dust and ash plant to mimic the plant performance behaviour.	Theoretical framework must be developed for the dust and ash plant maintenance problem to provide explanation and prediction of the phenomenon.
Research instruments used to build system dynamics model	Combination of interviews and group modelling with experts constituted 42% while the use of archival data had 21%. This observation in contravention of the positions of Forrester and Sterman (refer to table 5 above). Obtaining data from the mental models of the users was ranked the best by the two pioneers.	Quantitative and qualitative research instruments are vital for the SD modelling process and mental model data was ranked supreme.

10 LIMITATIONS

This study, which was published between 1981 and 2022. It was included in the Google database and conducted using English-speaking lenses. Although the 21 studies were obtained in the Google database, it may have overlooked any additional important studies that were published elsewhere or in languages other than English. Examples of include studies that were conducted in Arabic, Greek, Chinese, Spanish, French, Swahili amongst other languages and this was missed due to the design of inclusion criteria. Therefore, future studies should be mindful of English-based and one index searches and seek to include research from areas previously considered under-represented. This might include using other methods to identify system dynamics literature and making use of translation tools for non-English studies. Some of the studies' abstracts were incomplete as they did not include the salient findings and the author had to review such articles comprehensively to identify themes of interest. This shortfall in the studies could be a source of replication crisis [26] as the author could have been biased.

11 CONCLUSION

In this study, 21 published articles on the application of the system dynamics theory were applied using the systematic literature review and framework for doing thematic analysis were used to identify the above-mentioned themes.

Majority of the research problems were geared to solve the energy issues (29%) followed by project management (19%). The has also revealed that application of system dynamics covered wide spectrum as eleven different fields were covered. These included Water management, Quality, Manufacturing, Maintenance, Sustainability and Scheduling.

The author also found that the system dynamics research lacked structure as there was no alignment amongst the researchers using the same methodology. This could be source of replication crisis as the author could have been biased.

Sources of the publication came from Ph.D. theses (52%), M. Eng. theses (14%), Licentiate thesis (5%), Journals (24%) and Conference (5%) articles.

Theoretical frameworks applied in the studies were based on system dynamics theory. Most the studies (57%) were explicit about the theoretical coat that their studies were relying on while 43% did not come forth with the espoused theoretical coat.

Archival data (25%) was the single most common source of data but combination of interviews and group modelling with experts constituted 42%. Archival data position was in the least preferred according to Sterman while obtaining data from the mental models of the users was ranked the best.

Vensim (50%) was the most used software and the total number of software in these studies were five.

The publication in this study covered a wide spectrum dating from 1981 to 2022. Publications growth in this sample seemed to be stagnant but this is not agreement with the observations of the authors. This anomaly could have been caused by the research design that has yielded a sample that did not have the true characteristics of the main population. This was beneficial for the study as changes in the application could be noted in these studies.

The above-mentioned findings opened the road for the application of system dynamics model in the dust and ash plant based on the above-mentioned summary of the findings. These results are beneficial for future research of SD in the dust and ash plant maintenance modelling.

12 RECOMMENDATIONS

- Future reviews search strategy must be expanded so that the gaps identified in this study could be eliminated, that is to include other databases and languages translated through translation tools.
- Dust and ash plant maintenance model shall be developed in the future based on these learnings.

13 COMPETING INTERESTS

The authors declare that they did not have competing interests.

14 ACKNOWLEDGMENTS

The Ph.D. candidate would like to thank the University of South Africa (Unisa) for funding this research.

ABSTRACT

South Africa reported an unemployment rate of 30% in Q4 of 2022 of which youth unemployment contributed a staggering 64% to the total unemployment rate. Statistics South Africa estimates graduate unemployment for those aged 15-24 at 32.6% and 22.4% for those aged 25-34 in Q4 of 2022. Youth unemployment is a ticking time bomb, it is not surprising that the June 2021 uprisings befell Kwa-Zulu Natal Province and certain parts of Gauteng Province. Industrious entrepreneurs can revitalize the economy by creating jobs, developing, and deploying new technologies, and increasing efficiencies thereby improving the quality of life in countries. This paper attempts to explore the challenges and opportunities facing the engineering pipeline in the context of entrepreneurship and innovation. The article is envisaged to provide insights on measures that universities could undertake to trigger interest in industrial engineering students to pursue a career in entrepreneurship.

Keywords: Entrepreneurship, unemployment, universities, curriculum.

1 INTRODUCTION AND BACKGROUND

Unemployment is a socio-economic problem that is difficult to solve due to its complex and interconnected nature. Unemployment constraints economic growth, erodes business confidence, increases the number of dependents on social welfare, reduces productivity and competitiveness of the country; and places the country on a social time-bomb that could trigger a social uprising as the number of unemployed youth soars. The events that led to the July 2022 unrests stem from unemployment, poverty, and inequality.

The aim of this article is to provide a systemic view on the concepts of rising unemployment, perilous youth unemployment in the context of the engineering profession in South Africa which could be useful for policy makers in universities. To accomplish this task, the paper will explore the concept of unemployment, youth unemployment, entrepreneurship, and university curriculum in industrial engineering to instil a culture of entrepreneurship in industrial engineering students to create work rather than seek work.

The main research question is:

What can be done to inculcate the innovation and entrepreneurship culture amongst industrial engineering students?

To answer this pertinent question, the following sub-questions must be answered:

1. What is current entrepreneurship inspired culture in engineering education?
2. Which opportunities can be exploited to assist in solving the societal challenge of chronic unemployment?

2 LITERATURE REVIEW

2.1 Contextualising the phenomenon of graduate unemployment

Oluwajodu et al [1] argue that one of South Africa's most enduring and divisive economic issues is unemployment. The situation is much more dire for young people, endangering social security as well as the nation's long-term plans for economic growth and development. The important findings of studies documenting the worsening job market prospects for graduates in South Africa are consistent with findings from other countries that have suggested structural changes in other labor markets have resulted in a global trend of worsening job market prospects for those with Higher Education (HE) qualifications [2]. Figure 1 depicts a snapshot of the unemployment rates, expanded definition, absorption rate, and labour force participation rates in South Africa and its respective provinces as of 31 March 2023.

According to the precise definition of Statistics South Africa, more than a quarter (32.9%) of the labor force is unemployed. Most of the unemployed persons are Black Africans (32.7%) and Coloreds (22.4%), women (35.4%), residents of rural areas, those without post-secondary education, and young people. Indians sit at 14.3% unemployment rate while whites sit at 7.5% unemployment rate. According to the enlarged definition of unemployment, only 36.1% of 15- to 24-year-olds who are disengaged from the labour market, and they are also not building on their skills base through education and training [3]. This is notably a serious concern and a ticking societal time bomb.

This phenomenon is supported by Graham et al [3] argues that the massification in access to higher education and the worldwide economic collapse of 2008 are suspected to be behind the high rate of graduate unemployment globally, and South Africa is not an island and is affected by the same phenomenon. Graduate unemployment as a very emotive topic should be grounded within the broad context of high levels of unemployment levels in South Africa.

Figure 2 demonstrates that that of the 7,9 million unemployed persons in the first quarter of 2023, as many as 48,3% did not have matric, and 40,7% had completed matric. Almost 8% of the unemployed had other tertiary qualifications, while only 2,7% of unemployed persons were graduates which is a sizable number of graduates just below 216000 persons.

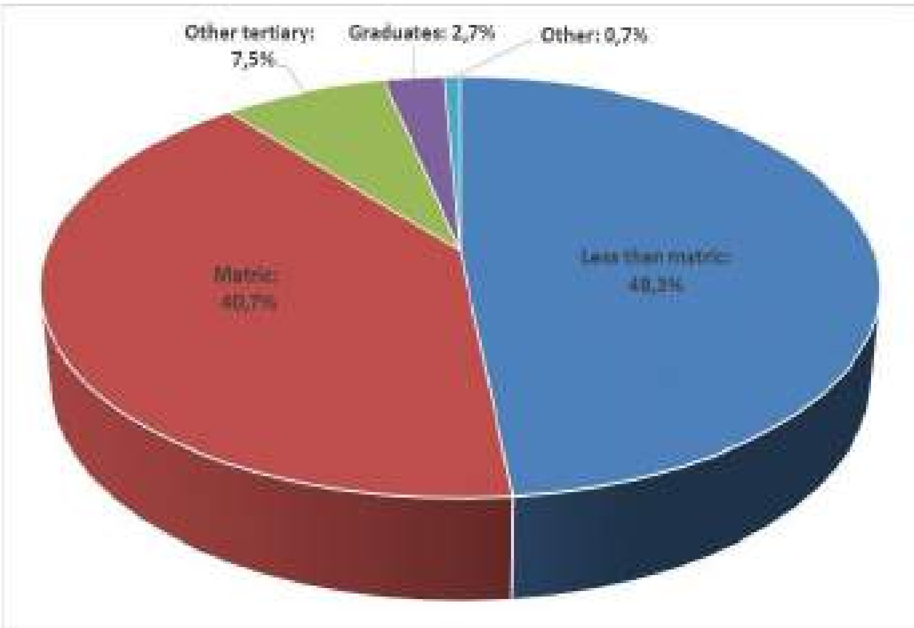

Figure 2: Proportion of the unemployed by education level

2.2 The concept of entrepreneurship education

2.2.1 The engineer

Litchfield et al. [4] advance that engineers have been esteemed for their technical proficiency for centuries. This skill has often distinguished engineers' role as civil servants who design and produce goods, services, infrastructure, and processes for the needs of humanity. Tenopir and

King [5] postulates that engineering products, services and applications are vital to everyday activities in our life. These include housing, transportation, communications, and other industrial processes. Considering safeguarding life, health, and property, and promoting public welfare, the practice of engineering is treated as a learned profession.

Khalid et al. [6] propose that engineers are understood to be authorities in their field of specialization and that is often where their expertise ends. The authors further advance that, engineers are good critical thinkers but often lack communication and interpersonal skills. This lack of interpersonal and communication skills may be attributed to the lack of importance given to these disciplines during their engineering education [6]. This view is supported by McKeag [7] who argues that one of the challenges facing engineering faculties is the matter of entrenching creativity and innovation into undergraduate and postgraduate programmes. He further argues that creativity was and continues to be erroneously perceived to be the realm of the arts, and the general understanding of innovation is any change. Connor et al. [8] take this argument further and challenge the common pedagogies found in STEM education with a particular focus on engineering. The authors argue that the dominant engineering pedagogy remains “chalk and talk”; despite research evidence that demonstrates its ineffectiveness. Such pedagogical approaches they argue, do not embrace the possibilities provided by more student-centric approaches and more active learning.

2.2.2 Entrepreneurial engineer

Davids et al. [9] propose that engineering is a field of study that applies science, mathematics, and technology to the existing world. Entrepreneurship on the other hand entails the introduction of a new product, introduction of a new technique of production, opening of a new market, establishment of a new supply source, establishment of a new industrial structure, and introduction of an innovation are five fundamental components of entrepreneurship. Entrepreneurship is a practice that starts with taking initiative and establishing a new business, a new entrepreneurial paradigm is introduced whenever a person starts a new venture [10]. Osipov and J. Ziyatdinova [11] postulate that education has generally neglected an integral aspect of humans nature, that human beings are moral and spiritual beings, and have to be trained in a positive way to develop the positive, ethical parts of our nature, which are not inherited but are learned. That raises the need to address character cultivation and character training in engineering education as entrepreneurs require character.

Sharma [12] concurs and argues that engineering is a very diverse profession that requires different skills. An engineer must perform various tasks, namely, technical supervision, personal management, project management, diagnostics etc. Moreover, in today’s global world an engineer is to be capable of intercultural communication to work with international partners and run joint projects. Therefore, engineering education aims at training an expert who has all these skills, however, providing technical knowledge in the field of profession obtained is not sufficient. Only humanities education can assist in developing special traits necessary for performing all engineering functions, and it is through humanities that character development and ethics can be incorporated into engineering.

Bruhl and Bruhl [13] advance the notion that engineers being educated and trained today not only be technically competent but must be creative and innovative. An important part of developing creative and innovative solutions is the framework within which students are taught to think and formulate ideas. This assertion points to the gap that exists between engineering and the arts and demands the transition from STEM (Science, Technology, Engineering and Mathematics) to STEAM (Science, Technology, Engineering, Arts, and Mathematics).

Boy [14] hypothesises that the 20th century was grounded on linear thinking to solve complicated problems, however, the 21st century has brought about complex interconnected problems in a connected world, this requires additional skills for engineers to deal with the complex challenges of the 21st century which requires critical thinking, collaborative, creativity and dealing with complexity skills.

3 RESEARCH METHODOLOGY

Khothari [15] proposes that research is a scientific and systematic exploration for relevant information on a specific topic. This research is a scientific and systematics exploration of literature relating to the concepts of unemployment and entrepreneurship education in engineering programmes. The study adopted an interpretivist philosophical worldview followed by an inductive approach. The study further adopted a qualitative methodological choice and a archival research strategy which entailed a review of secondary data from the respective universities.

In this study, a sample of industrial engineering programmes across public South African universities is surveyed. The engineering sciences and engineering technology programmes will be separated so that a fair comparison can be drawn. Three engineering science and three engineering technology institutions were surveyed. The research will only focus on engineering programmes that have full accreditation from the Engineering Council of South Africa (ECSA). Finally, the entrepreneurship related subjects offered in these engineering programmes will then be grouped to allow fair comparison. The limitation of this method is that some of the entrepreneurship curricula could have been incorporated into some modules. If this is true, it is easy that the reviewer could have missed this information. Therefore, the methodology utilized in this study assumes that entrepreneurship knowledge is implemented in the engineering programme as a standalone module.

4 FINDINGS AND DISCUSSION

4.1 Engineering sciences programmes (Entrepreneurship inclined modules)

Table 1 depicts the entrepreneurship inclined modules in the engineering science programmes in industrial engineering at University of Pretoria, University of Witwatersrand, Stellenbosch University and Northwest University.

5 DISCUSSIONS

The results point to variations in entrepreneurship-inclined programmes in universities, these variations are not only between engineering science programmes and engineering technology programmes, but variations exist within the respective programmes as standalone. The section below discusses the programmes as standalone.

5.1 Engineering science programmes

University of Pretoria (UP) and Northwest University (NWU) offer business engineering in third year which to smaller extent covers some aspects of entrepreneurship while Wits University (Wits) offers Business studies which also covers to a smaller extent aspect of entrepreneurship. The curriculum of Stellenbosch University (SUN) does not reflect any entrepreneurship module or an entrepreneurship inclined module. UP, NWU, and Wits offer their entrepreneurship inclined modules at the third-year level of the Bachelor of Engineering (BEng) programme.

5.2 Engineering technology programmes

The same variations that exist in the engineering science programmes exist in the engineering technology programmes with University of Johannesburg offering Entrepreneurship at third-year level in their Bachelor of Engineering Technology (BEng Tech) programme while the University of South Africa offers Engineering Entrepreneurship at Advanced Diploma level which is at third-year level. The curriculum of Cape Peninsula University of Technology (CPUT), the Tshwane University of Technology (TUT), and the Durban Institute of Technology (DUT) do not reflect any entrepreneurship module or an entrepreneurship inclined module.

It is noteworthy that the University of Johannesburg and the University of South Africa offer tailor made entrepreneurship modules in their respective programmes, University of South Africa offers engineering entrepreneurship which attempts to steer entrepreneurship from general entrepreneurship to technology inclined entrepreneurship. However, this module still requires improvement to incorporate innovation, a cornerstone of entrepreneurship.

6 RECOMMENDATIONS AND CONCLUSION

The world is faced with far-reaching revolutionary changes shepherded by the digital age, which is changing the world as we know it. The engineering profession is not immune to these sweeping changes driven by VUCA. Engineers trained today should be able to deal with this volatile, uncertain, complex, and ambiguous world. One of the leading wicked problems faced by South Africa is chronic high unemployment The literature reviewed points to the lack of a standard approach to embedding entrepreneurship in engineering programmes from both engineering science and engineering technology perspectives. The modules offered that are entrepreneurship-inclined are a good start but not sufficient to instil a culture of entrepreneurship amongst engineering students. Entrepreneurship is a mindset that requires inculcation of a culture of innovation and seeking to succeed in business.

It is noteworthy that (1) Some of the universities have stated to move in the right direction to train students in the exciting field of entrepreneurship (both engineering science and engineering technology) to respond to national challenge faced by South Africa, however none (2) of the universities integrates innovation and creativity in their respective modules.

Innovation is the foundation of successful entrepreneurship as entrepreneurs are in the business of finding gaps in the market and filling the gaps with the necessary speed of execution.

The gap acknowledged in this study is a fragmented approach towards engineering entrepreneurship in the engineering curriculum. The embedding of entrepreneurship together with innovation will develop the creativity and innovativeness character of the student, a systems view of entrepreneurship module will develop a character of students that can deal with complexity, uncertainty, and ambiguity.

As a recommendation for an effective and efficient Science Engineering Technology and Entrepreneurship (SETE) programme in universities, a technology entrepreneurship module should be considered for implementation in engineering science programmes and engineering technology programmes and should cover the following topics:

- Team dynamics
- Elevated pitching and presentation skills
- Entrepreneurial ethics
- Creativity and innovation
- Navigating from idea to opportunity
- Patent engineering
- Technology venture financing
- Marketing for engineers
- Strategic management dynamics

Incorporating the proposed topics is likely to develop an entrepreneurial industrial engineer of the future during their journey in university and this will potentially contribute towards dissolving the wicked societal problem of unemployment.

ON THE FIXED CHARGE SOLID LOCATION AND TRANSPORTATION PROBLEM WITH TRUCK-LOAD CONSTRAINT: A CASE OF UNSUPERVISED LEARNING MEETS OPTIMISATION

G.J. Oyewole[1*]
[1]School of Mechanical, Industrial, and Aeronautical Engineering
University of the Witwatersrand, South Africa
gbeminiyi.oyewole@wits.ac.za

ABSTRACT

Advances in machine learning have made optimisation methods receive more intelligent inputs to give more reliable outputs. In this paper, the Fixed Charge Solid Transportation Problem with Truck-load Constraint (FCSLTP-TLC) is studied. This problem considers that shipment cannot be done in one lot, decides on the facility location, and obtains its demand input through clustering of demand predictions. Using an adapted K-means clustering technique, the demand predictions are used to select the final demand and compared to possible final demand obtainable from measures of central tendencies such as the mean and mode. The optimisation model is solved and results from the different demands are analysed to determine possible cost savings and more importantly other learnings from the data input technique. This model is useful to academics and industry practitioners in gaining insight into the impact of selected unsupervised machine learning models on optimisation decisions.

Keywords: machine learning, clustering analysis, fixed charge solid transportation problem, Facility location, mathematical optimisation

1 INTRODUCTION

Machine learning methods have continued to digitally revolutionise business operations in the form of making good predictions to support business operations. For example in the manufacturing and logistic sector, the prediction of failure rates of production processes [1], Strengthening supply chain resilience [2] and predicting road traffic accidents [3] has been beneficial to the sector.

These predictions have taken the form of a supervised learning method which essentially involves training the machine using selected features of inputs and corresponding output/labels. On the other hand, unsupervised learning rather than making predictions for a course of action, analyses unlabelled datasets. For example, clustering analysis (an aspect of unsupervised learning) suggests hidden patterns within the dataset thus opening the decision-maker to a wide range of possibilities than predicting a specific value.

Optimisation models essentially are concerned with selecting the best course of action or decisions given certain constraints and input variables [4]. Often, sensitivity analyses are conducted to ensure the model becomes robust through different constraints and input variables. These input variables could be known with certainty (deterministic) or without certainty (stochastic or following some probability distribution). For example, demand uncertainties in distribution problems have been studied by [5]. Furthermore, distribution problems in which certain route-limiting constraints are imposed during the shipment were studied by [6] and [7].

Uncertainty in input data for decision-making could be handled through sampling probability distributions such as the Monte Carlo sampling, the use of stochastic programming, and the use of measures of central tendency such as the mean [8]. However, the Monte Carlo simulation and stochastic programming may become intractable as data size increases [8], [9]. In addition, these methods may not well reveal patterns in a dataset which are obtainable using the knowledge extraction powers of unsupervised learning techniques such as clustering [10].

Moreover looking at the current advancement in capturing large amounts of data as noted by [11] in their study (using the case of logistics, where the use of smart data sensors such as RFID(Radio Frequency Identification), wireless adapters, vehicle tracking sensors, GPS (Global positioning system) could provide a vast amount of varied data) the possibility of using other intelligent techniques to understand and quantify the complexity in such datasets becomes important. The datasets having been further understood could be fed into optimisation models to provide more robust decisions. Furthermore, with the possibility of running digital/web surveys for experts in a certain domain (within or outside a business enterprise) to capture their opinions, the need to rely on intelligent methods such as clustering techniques that could reveal hidden patterns within the data collected arises.

We state the research question of this study as "*What are the possible learnings in applying an unsupervised learning technique such as K-means clustering in determining uncertain data parameters in an optimisation model?*". Therefore, this article seeks to investigate the impact of a selected unsupervised learning technique (K-means clustering) on a typical optimisation decision. Specifically, the distribution problem where the shipment cannot be done in one lot and considers the facility location decisions is studied. The aim is to demonstrate this concept and possible learning that could be achieved from this case of unsupervised learning meets decision. The term "unsupervised learning meets decision" refers to capturing some form of data science techniques into traditional decision-making problems for better decision-making. This concept is generally known as data-driven decision-making [12].

2 METHODS AND DATA GENERATION

In this section, we first present the optimisation approach and later discuss our data collection procedure. The optimisation model is a rehash of the FCSLTP-TLC described in [13]. Our data collection procedure is primarily based on random number generation. The model parameters for the unit cost and capacities follow probability distributions as obtained from [13], [14]. In this study, we have assumed demand is uncertain and only obtained from different expert opinions about previously known demand. The basic approach we followed was to cluster the expert demand predictions and adapt the clustering results as inputs into our optimisation model. Figure 1 shows the optimisation problem while Figure 2 shows how the clustering meets the optimisation model by fitting into each demand destination respectively.

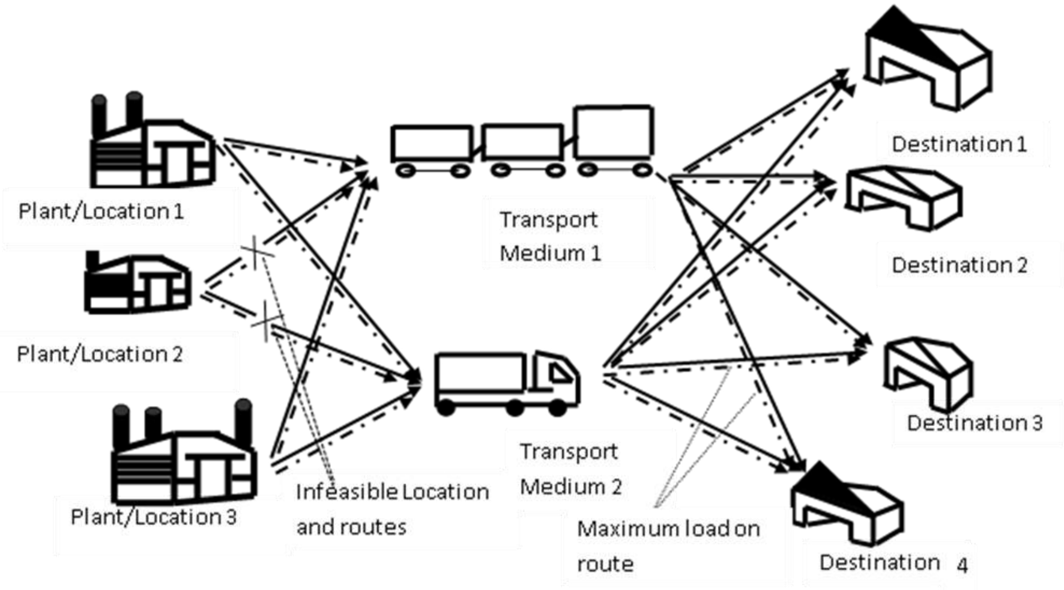

Figure 1: Fixed Charge Solid Location and Transportation Problem with Truck-load Constraint [13]

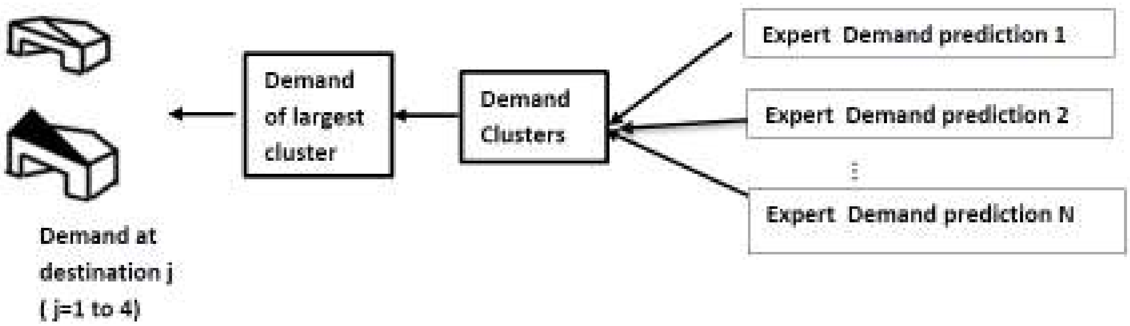

Figure 2: How the unsupervised learning meets the optimisation model

2.1 Optimisation model for the FCSLTP-TLC

2.1.1 Optimisation model parameters

i: Index representing source locations such as manufacturing sites, distribution points warehouse etc.)

j: Index representing demand points such as clients, customers, other warehouses etc.)
r: Index representing capacitated transport vehicles or mediums.
m: representing the number of source locations.
n: representing the number of demand or destination points.
a: representing the number of capacitated transport vehicles or mediums.
c_{ijr} : per unit cost of shipment on route (i, j) by transport vehicle r.
S_i : representing the capacity of source i $for\ all\ i = 1 \dots m$.
D_j: representing Demand at destination j $for\ all\ j = 1 \dots n$.
T_r : Capacity for the transport vehicle r $all\ r = 1 \dots a$.
F_i: Source location fixed cost at i.
H_{ijr} : route fixed cost of shipping through(i, j) by transport vehicle r
W_{ijr}: Maximum shipping permitted through route (i, j) transport vehicle r

2.1.2 Optimisation Model Decision Variables

x_{ijr}: Product quantity shipped from source (i) to demand point (j) using transport vehicle (r)
y_i : Binary variable (0,1) representing opened (1) or closed (0) source location i
z_{ijr}: Integer variable representing one or multiple fixed charges incurred on route (i, j, r)

2.1.3 Objective function of the FCSLTP-TLC

This is given as

Minimize (FCSLTP-TLC):

$$\sum_{i=1}^{m} F_i y_i + \sum_{i=1}^{m} \sum_{j=1}^{n} \sum_{r=1}^{a} c_{ijr} x_{ijr} + \sum_{i=1}^{m} \sum_{j=1}^{n} \sum_{r=1}^{a} H_{ijr} z_{ijr} \quad (1)$$

Subject to

$$\sum_{j=1}^{n} \sum_{r=1}^{a} x_{ijr} \leq S_i y_i \qquad \forall\ i = 1 \dots m \quad (2)$$

$$\sum_{i=1}^{m} \sum_{r=1}^{a} x_{ijr} = D_j \qquad \forall\ j = 1 \dots n \quad (3)$$

$$\sum_{i=1}^{m} \sum_{j=1}^{n} x_{ijr} \leq T_r \qquad \forall\ r = 1 \dots a \quad (4)$$

$$z_{ijr} = \begin{cases} Integer\ part\ of\ \left({x_{ijr}}/{W_{ijr}}\right) + 1 & if\ x_{ijr} > 0\ and\ remainder\ \left({x_{ijr}}/{W_{ijr}}\right) > 0 \\ Integer\ part\ of\ \left({x_{ijr}}/{W_{ijr}}\right) & if\ x_{ijr} > 0\ and\ remainder\ \left({x_{ijr}}/{W_{ijr}}\right) = 0 \\ (\ 0\ ) & if\ x_{ijr} = 0 \end{cases}$$

$$\forall\ i = 1 \dots m,\ \forall\ j = 1 \dots n,\ \forall\ r = 1 \dots a \quad (5)$$

$$y_i = 0\ or\ 1 \qquad \forall\ i = 1 \dots m \quad (6)$$

$$x_{ijr} \geq 0 \qquad \forall\ i = 1 \dots m,\ \forall\ j = 1 \dots n,\ \forall\ r = 1 \dots a \quad (7)$$

(1) is an expression that represents the minimization cost function of the FCSLTP-TLC.

The first term represents the total facility location cost. The second term represents the route variable cost (transport vehicle dependent). The third term represents the route fixed cost incurred per conveyance type due to truckload constraint.

Equation (2) is a constraint that makes the supply capacity not exceeded.

Equation (3) is a constraint that makes the demand to be met at each destination.

Equation (4) is a constraint that makes the conveyance capacity not exceeded.

Equation (5) is a constraint that represents the maximum shipment per route requirement (the truckload constraint).

Equation (6) represents the facility location requirement.

Equation (7) refers to the non-negativity constraint for the continuous variables.

2.2 Demand values for the FCSLTP-TLC

2.2.1 Generation of Expert demand predictions

The continued importance of demand to the continued operations of any business venture has led our focus on isolating the demand (Dj) as a variable to be generated through expert opinions.

In this study, we have assumed the possibility of experts providing an opinion based on knowing previous values of the demand. As this study is focused on showing the workings and impact of unsupervised learning (K-means) on our optimisation procedure, we have randomly generated the experts' considerations and predictions using mathematical expressions.

The expert demand prediction is generated using a combination of the multiplicative congruential random number generation method [9] and an adaptation of a method for generating discrete random variates [15].

We used the multiplicative congruential method to generate the different expert probabilities around a given previous demand, while the discrete random number generation was used to obtain discrete values that represent expert demand forecast. The expressions below describe the expert demand generation.

Step 1: Randomly obtain the number of experts to use. (This in real cases often depends on the available experts or the number of experts from a survey that can provide a representative sample to the study). For the study 100 was used.

Step 2: Multiplicative congruential random number generation method.

This is given using the recursive function:

$$X_n = (b * X_{n-1} + c) \text{ Modulo m} \quad \textbf{\textit{(8)}}$$

$$Rn = Xn/m \quad \textbf{\textit{(9)}}$$

Expression (8) generates a sequence of random integers $X_1, X_2, \ldots, X_n$ with the starting X_0 defined as a seed. In this study, the X_0 represents the previous actual demand.

Expression (9) finally converts the random integers into a number between 0 and 1 to represent the expert probabilities. The terms b is a constant multiplier, c is the increment and m is the modulus.

These values are carefully selected to ensure the stream of random number generation is not cycled. For this study, b = 13, c =64 and m = 150 is arbitrarily selected to ensure the random numbers obtained are not cycled. It will be interesting to consider in future studies the effect of varying these numbers on the quality of the numbers generated.

Step 3: Adaptation discrete random variates generation

To arrive at the Expert demand (Y) representing their predictions,

$$Y\ (predicted) = X_0 + INT\ [(100 - X_0 + 1) * R_n] \quad if\ R_n >= 0.5 \qquad \textbf{(10)}$$

$$Y\ (predicted) = X_0 - INT\ [(100 - X_0 + 1) * R_n] \quad if\ R_n < 0.5 \qquad \textbf{(11)}$$

0.5 or 50% in equations 10 and 11 is used as a threshold for R_n to ensure predictions above and below the previous real values were obtained.

2.2.2 Demand (Dj) *from Expert Predictions*

K-means Clustering

The K-means clustering algorithm as an example of unsupervised learning was selected due to its popularity in clustering studies[12], its fitness to our numeric data and its relative ease of implementation. The K-means clustering was implemented to understand hidden patterns in the expert demand (Y) dataset. The k-means clustering groups a dataset by iteratively optimizing a particular similarity/dissimilarity measure or distance function such as the Euclidean distance. We refer readers to [16] for more detailed discussions of the workings of the K-means algorithm. The K-means require the determination of the number of groups or clusters in the data set before clustering. We used the method of NbClust [17] to obtain the number of clusters. The NbClust uses 30 validity indices and a majority rule to select the best number of clusters.

Prediction of Demand

Since clustering as a form of unsupervised learning does not make predictions but shows hidden patterns we used a method similar to the operations of the K-nearest neighbour classification method [18]to obtain the predictions by considering the cluster with the largest size and using the cluster means (centroid) obtained as the label of the entire clusters of data points. Ties between similar cluster sizes are broken by finding the average of the cluster means of their respective clusters. Means. Fractional K-means values and the mean of the expert predictions were rounded off to the nearest whole numbers. Figure 3 below presents a description of the major steps in the methods of this study.

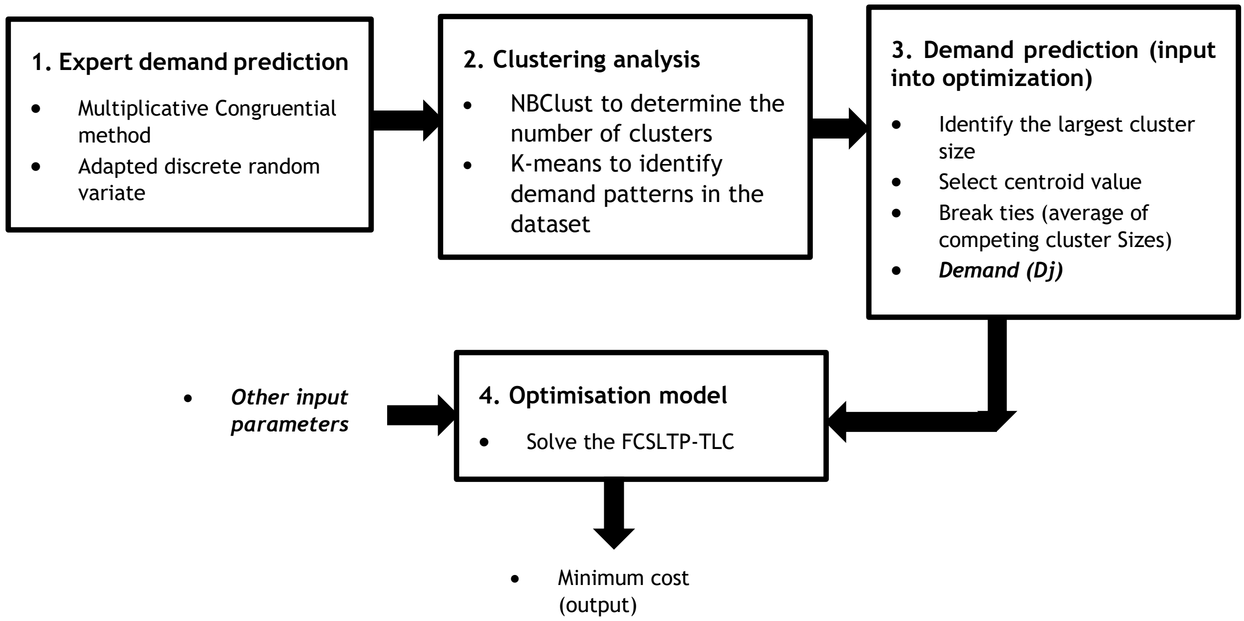

Figure 3: Summary of research methods in the Study

2.3 Data Generation

2.3.1 Other parameters apart from the demand

The cost inputs such as the facility fixed cost (F_i), unit cost (c_{ijr}), fixed route cost (H_{ijr}) and other inputs parameters were obtained from probability distributions from the literature [13], [14] and presented in Table 1 below:

Table 1: Input data into the optimisation model

Parameter Distribution
S_i : U(200, 400) T_r : U(200, 500) c_{ijr} : U(20, 150) H_{ijr} : U(200, 600) $F_i = U(0,90) + \sqrt{S_i}\, U(100,110)$ $W_{ijr} = \ x\,\%\ of\ \ Max\ \ D_j$ $0 < x < 100$ $x = 50\%$ (selected for experimentation) D_j => Current demand obtained using the approach in section 2.2.2 D_p => Previous demand at each destination j U(40, 100).

3 EXPERIMENTATION

3.1 Experiments conducted

The main aim of our computation experiments in this study is to test the approach of using K-means clustering as a method of deciding certain input parameters into our optimisation model.

Furthermore, this approach is compared to using measures of central tendencies such as Mean and Mode to see the robustness of the clustering algorithm in providing hidden data patterns that could provide some noteworthy measures. The optimisation model seeks to obtain the minimum cost which in most cases is used as a measure of profitability for business ventures. Given different approaches to obtaining the demand it is our interest to see the possible cost trade-offs with these methods.

To demonstrate the workings of this method we present a simple problem size of 5 sources, 5 demand points and 2 Transport vehicles. We specifically note that clustering results in addition to the specific clustering tuning parameters selected can be skewed to the type and size of data obtained. Hence running multiple problem sizes due to the random nature of this method are by no means exhaustive and may not be sufficient to show the superiority of any of the demand-generating approaches we have considered. Rather, the workings of this method are presented as the potential to show positive or negative interesting results that could be obtainable when inputs generated from data mining are used. The input parameters specific to this problem are represented in Table 2 below. The numbers have the same units and represent any measure of capacity used in transporting commodities e.g. kilograms.

Table 2: Input Parameters of the case studies

Capacity at Source (S_i)	Transport vehicle capacity (T_r)	Previous demand at destination j ($D_{p,j}$)
298	200	50
245		60
201	250	70
286		80
256		40

3.2 Instrumentation

The optimisation model was written on the Eclipse development platform using Java and the IBM ILOG CPLEX version 12.8 as the mixed integer programming solver. As noted in [19], the CPLEX solver uses methods such as the branch and cut in optimally searching the solution space for a certain class of combinatorial problems such as linear programming, mixed-integer programming, and mixed-integer quadratic problem. The NBClust and K-means were performed using the R studio version 4.2.0. Other data analysis was performed on Microsoft Excel.

4 RESULTS AND DISCUSSION

4.1 Results

The clustering results obtained for the 100 predictions representing the expert opinions based on previous actual demands are represented in Table 3 below. This also includes the mean and mode of the predictions. The abbreviations in Table 3 are defined as follows:

The index for the demand or destination point is represented by j. Previous demand at demand point j is represented by Dp,j. The number of observations of expert prediction at demand point j is represented by Np,j. The best number of clusters suggested per demand point (using NBClust) is represented by Cluster No. (j). The value of the largest-sized cluster is represented as K-means. The arithmetic mean of all the expert demand predictions is represented by Mean. The highest recurring value of the expert predictions is represented by Mode. Lastly, the Naïve value represents using the previous demands directly as the current demand.

Table3: K-means clustering result, mean and mode of demand predictions

j	Dp,j	Np,j	Cluster No. (j)	K-means	Mean	Mode	Naïve value
1	50	100	2	39	62	88	50
2	60	100	14	92	70	96	60
3	70	100	2	93	78	91	70
4	80	100	8	73	85	73	80
5	40	100	2	26	53	27	40
Total demand j(1…5)				323	348	375	300

The table further shows the possibilities of different numbers of clusters that can be obtained for the 100 observations of each demand point. As illustrated in Figure 4 below, The K-means means and mode all present varying demand predictions across the five demand points, with the K-means showing close similarity to the Mode compared to the Mean (The Mean tends to present a central or average measure across the dataset). The comparison among the different predicted values is further illustrated in Figure 4.

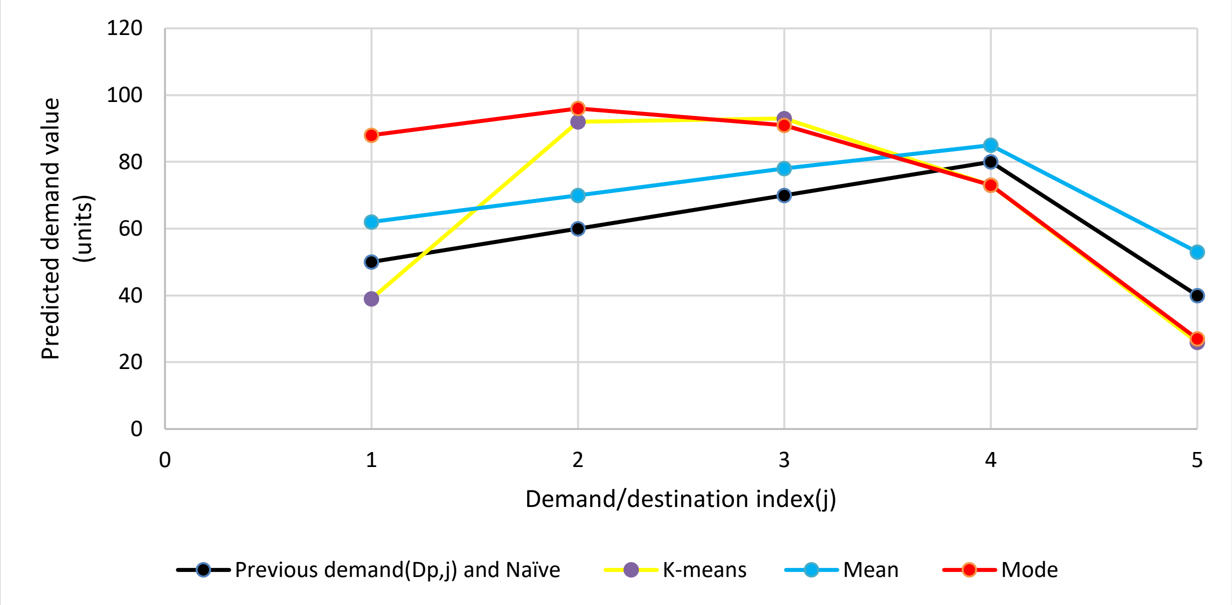

Figure 4: Predicted demand comparison among the four demand prediction methods

Table 4 below shows a comparison of the minimum cost obtained using three demand prediction methods including the Naïve forecast.

Table 4: Optimisation results

Method of obtaining demand	Optimisation result (minimum cost function)
K-means (largest cluster)	20 092
Means of the dataset	20 517
Mode of the dataset	21 816
Naïve (previous demand)	18 423

In this result, the Mode is shown to perform worse than the K-means and Mean(average) in predicting demand values for the minimum cost optimisation problem.

4.2 Discussions

Looking at the results of Table 3 we can see how different demand values are obtainable using selected measures of central tendencies and the K-means. The K-means also tries to provide a central or centroid value for the different clusters obtained from the dataset.

Data-sensitive studies such as this often depend on the type and number of data points used. Therefore, due to the limited datasets used, we would emphasize the possible learnings and gains from this technique rather than the limited gains or losses from an instance of the demand prediction methods.

The utility of our demand prediction methods is such that we have a range of possible demand values to consider when the real or actual demand is not known. On one hand, this could act as a technique of providing an objective sensitive analysis due to the uncertainty in demand. For example, If we consider that all the demand is met by the source location at a unit selling price of 100, then the largest profit will be provided by the mode. This might show a higher bound of profit tending towards being unrealistic compared to a lower bound from the K-means that might be more realistic or closer to the Naïve prediction that would use the previous actual demand as the value for the new prediction.

On the other, the use of methods that can further reveal hidden patterns in the data set might provide more interesting results for optimisation input data as well as the objective function, rather than using a conventional Mean or average of possible demand prediction values, the choice of selecting the mean of the largest cluster from the K-means could reveal a group of experts that provide good similar predictions. These predictions can give a higher confidence in accepting their predictions rather than just a general average of all predictions that might be naïve of certain intricacies in the dataset. Furthermore, when the actual results are known, more research or investigation could be conducted on the rationale behind the expert's selection of a certain range of values for the prediction. This is necessary because only the values of the expert predictions are considered and not the methods of arriving at their predictions.

5 CONCLUSION AND FUTURE DIRECTION

An integrated distribution problem where the shipment cannot be done in one lot and considers the facility location decisions were studied. The focus of the study was on the impact of unsupervised learning methods such as clustering in providing a technique to understand input data into optimisation problems. Considering the fact that there could be different observations of data which we have termed expert predictions around a previously known value creates a problem that could hide certain patterns in the data which might be relevant for the optimisation in providing a more reliable result.

The example we have considered shows the K-means as providing the minimum cost but can contribute to a lower realistic profit, compared to the possible higher cost and profit from the mode which can tend towards being unrealistic. Ultimately the results obtained will depend on the type of real data being studied.

It will be interesting to apply the demand-generating methods we have utilised on a range of actual datasets. Also given real expert predictions, the use of different unsupervised learning techniques such as clustering analysis, principal component analysis, and factor analysis can be implemented. In addition to the K-means clustering, other clustering analysis methods useful for numeric data such as hierarchical clustering, K-medoid, and K-mode can be further tested on their impact on the input data and the optimisation decisions. Lastly, different problem sizes can also be implemented using the methods considered in this study to compare how this technique works in a pattern of datasets.

ABSTRACT

Industry 4.0 technologies are transforming manufacturing processes globally, with potential implications for quality management (QM) practices. A systematic literature review was conducted to investigate the impact of Industry 4.0 on QM practices, using PRISMA to gather data from reputable databases. Out of 29 papers selected for the final quantitative analysis, the study found a significant increase in publications on the topic since 2016. The study revealed that Industry 4.0 could significantly impact three QM practices: evidence-based decision-making, process management, and customer focus, by enabling real-time quality monitoring and control and improving traceability and transparency. The study also identified challenges associated with the integration of Industry 4.0 technologies, such as data accuracy, cybersecurity, employee training, and integrating technologies into legacy processes and systems. The findings in this study are beneficial for manufacturing professionals and researchers in the field of quality management.

Keywords: Industry 4.0, Quality Management, Quality 4.0

1 INTRODUCTION

Studies have claimed that manufacturing is the backbone of any country's economy and globalization provides firms with worldwide access to markets. Consumers are now confronted with a broader range of available products and, as a result, their requirements are becoming more fluid, and they have begun to scrutinize the quality and value of the goods and services on which they spend their money [1], [2]. Consequently, businesses use quality to set themselves apart from their competition.

According to Najmi et al. [3], Hurta and Noskievičová [4], and Chouchene et al. [5], the concept of quality is not new and the popularity of managing quality stretches back more than four decades. Throughout modern history, several quality management (QM) initiatives have emerged, typically in response to industrial revolutions. However, quality management has been stagnating for a long time. Manufacturers' constant product recalls and loss of consumers demonstrate the stagnancy in quality management.

The risk is that over the last decade, engineering and manufacturing techniques, processes, and technology have changed, and these developments are expected to result in the resurrection of engineering and manufacturing operations [2], [5], [6]. This phenomenon is known as the fourth industrial revolution (Industry 4.0/4IR), and it is characterized by major enablers such as big data and analytics, cyber-physical systems, blockchain technology, autonomous robotics, artificial intelligence (AI), virtual reality and the internet of things (IoT), which enable vertical and horizontal integration and interconnection [1], [2], [7].

These Industry 4.0 technologies enable, inter alia, mass production and product customization and, as a result, production processes become more complicated, necessitating the creation of new QM techniques [6], [7], [8]. Firms find it challenging to rely on prior successes and traditional strategies in the present business environment. As a result, recent articles suggest that current QM strategies are out of date and must be revised to respond to new quality concerns resulting from this new revolution [9], [10], [11]. Several studies have even advocated the digitization of quality management practices to address quality challenges in the fourth industrial revolution, dubbed Quality 4.0 [2], [11], [12].

The objective of this research is to examine the impact of digitizing quality management procedures in the manufacturing industry. It emphasizes the need for gathering data and identifying common themes to comprehend the effects of Industry 4.0 on conventional quality management practices. The ultimate aim is to motivate manufacturers to incorporate 4IR technologies into their existing quality management approaches, thus boosting operational efficiency and enhancing product quality for consumers. This study adopts a systematic literature review to analyse the impact of 4IR in the manufacturing sector.

2 THEORETICAL BACKGROUND

2.1 Industry 4.0

The expression "industry 4.0" denotes the fourth industrial revolution (4IR), which was initiated by technological progress and the integration of computers and the internet into industrial processes, facilitating instantaneous information dissemination and a significant level of independence and automation across the entire value chain. Cyber-physical systems (CPS) are leading the charge in 4IR, merging the physical world with advanced information technology to improve future industrial production [1], [6], [11], [12],[13]. However, it is important to acknowledge the three prior industrial revolutions.

The first industrial revolution (1IR), which Britain pioneered and monopolized from 1760 to 1830, was ignited by the development of steam power. This started the move from an emphasis on human labour to an emphasis on machines. This led to a socioeconomically significant increase in manufacturing [14], [15].

Electricity, assembly lines, and the invention of steel were among the innovations that brought about the second industrial revolution in the nineteenth century. This influenced manufacturing activities, boosting outputs and cutting costs. Automation increased as a result of the development of electronics and information technology in the third industrial revolution around the 1950s [16].

Unlike the previous industrial revolutions that relied on a single dominant technology, the fourth industrial revolution (4IR) is a convergence of cyber and physical technologies. Various technologies such as Artificial Intelligence (AI), machine learning (ML), 3D printing, IoT, augmented reality (AR), cloud computing (CC), big data and analytics (BDA), and blockchain technology have emerged since 2011, and they have significantly impacted industrial operations [9], [12], [16]. AI can optimize production processes, predict equipment failure and enhance product quality, while ML can be used to analyze data to improve process efficiency and quality. Furthermore, 3D printing can create prototypes, produce personalized products, and minimize waste.

IoT can monitor equipment and processes in real-time, enabling predictive maintenance and optimization. Augmented Reality can provide real-time information and guidance, improving safety and efficiency. Cloud Computing can store and analyse large amounts of data, providing real-time access to production information. Big Data and Analytics can analyse data to improve decision-making, optimize production processes, reduce waste, and improve quality. Blockchain technology can track and verify the origin and movement of products and materials, improving supply chain transparency and efficiency. The smart manufacturing sector is characterized by 4IR's capacity to affect product design, production, quality, and delivery.

2.2 Quality and quality management

Although the idea of quality is not new, there is still no agreed-upon definition; however, fitness for purpose is a universally acknowledged criterion. On the other hand, quality management refers to a set of procedures that entails planning, coordinating, and regulating activities geared towards ensuring that a given product or service meets or surpasses customers' expectations [7], [10], [11]. This involves establishing quality benchmarks and objectives, monitoring and evaluating the product's or service's performance, identifying areas that require improvement, and implementing corrective and preventive measures to achieve the intended level of quality. The primary aim of quality management is to consistently enhance the quality of products or services to promote customer satisfaction and loyalty. Quality management had important development stages, moving from statistical quality control (SQC) to quality assurance (QA) and ultimately, as concerns about quality increased in the 1970s and 1980s, to total quality management [7], [8], [9], [16].

There have been several quality revolutions, largely driven by the Industrial Revolution. Quality 1.0 was characterized by measurement and quality control, while Quality 2.0 emphasized quality control. Quality 3.0, during the third industrial revolution, adopted quality management as a strategy, based on principles such as customer focus, process management, and information-based decision-making. Currently, Quality 4.0 integrates digitization and cyber-physical systems (CPS) into established quality management systems and procedures, utilizing the features and technologies of 4IR [7], [8], [9], [11]. Quality 4.0 is a subcategory of Industry 4.0 and aims to enhance quality through intelligent systems and smart solutions without replacing existing quality management practices [15], [17].

3 RESEARCH OBJECTIVES

The systematic adoption of Industry 4.0, as 4IR is also known, has in the last decade addressed the limitations of traditional quality management practices. As a result, this paper aims to conduct a systematic literature review to assess the impact of 4IR on traditional QM practices, and to identify similar trends, consensus, and gaps in the literature.

4 METHOD

The time frame, the research topic, the sources or databases from which the data is gathered, the methodology, and the inclusion and exclusion criteria were all factors considered when determining a search strategy that would yield the best results.

4.1 Time span

This study had a time span of 10 years.

4.2 Research terms and databases

The primary search terms utilized in this study were "Industry 4.0" AND "Quality Management" AND "Manufacturing”. The study also considered related combinations such as "Quality 4.0", "Quality Management 4.0" and "Digitalization of Quality Management". Additionally, the study included articles that concentrated on "Industry 4.0" and "Quality Control/Quality Assurance". A literature search was carried out across the following reputable databases: Scopus, Emerald, and IEEE Xplore.

4.3 Inclusions and exclusions

This study included only articles that answered the research question, were published in the above-mentioned databases, and were published in English. The study did not include publications that tackled sectors other than the manufacturing sector or were incomplete.

The study also utilized a quality assessment technique followed by Maganga and Taifa [16] and Javaid et al. [17], which requires that the completeness of each included publication be evaluated. The publications' study design, research technique, and conclusion were evaluated using the criteria of "yes," "no" and "partially”.

4.4 The research methodology

To find peer-reviewed publications and conference papers, Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), as shown in Figure 1, were used to collect articles from different sources. The first search, applying all the above-mentioned inclusions and exclusions, yielded 141 papers on IEEE Xplore, 9 papers on Emerald, and 1055 papers on Scopus. A further 32 papers were found on Google Scholar, another field whose results were accepted.

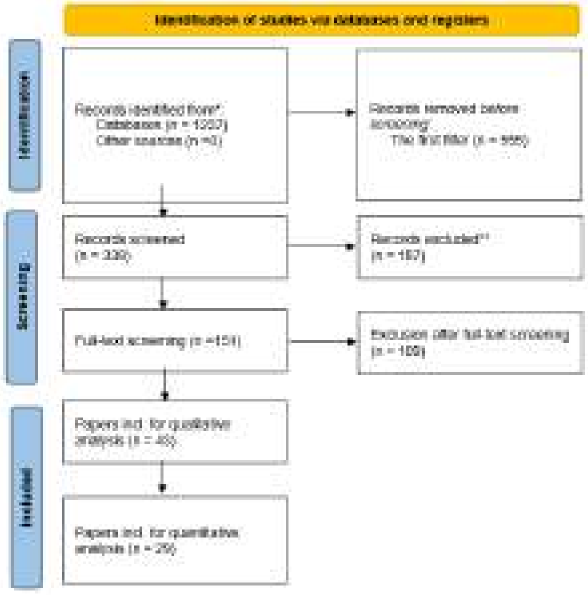

Figure 1: Number of papers identified by PRISMA

The articles were then screened using the title and abstract and those not related to the research question were eliminated, leaving 555 papers in total. Duplicates, and articles that did not review the manufacturing sector were also eliminated leaving 338 papers to screen further. The methodology and findings of each paper were read, and more papers were eliminated if their findings would not contribute to this study, leaving 151 papers that were then screened in their entirety. Of these papers, 43 were included in the final qualitative study, of which only 29 papers were used in the final quantitative study.

The text was analysed using both quantitative and qualitative methods. In this situation, qualitative procedures included reading the articles with comprehension and identifying and grouping themes/similar patterns that emerged during the investigation. Quantitative approaches were used to summarize the grouped themes and numerically represent the articles per year, per journal, and per appearance of 4IR technologies.

5 FINDINGS AND DISCUSSION

	2016	2017	2019	2020	2021	2022
Number of Publications/Year	1	2	3	5	9	9

Figure 2: Number of accepted papers by year

Figure 2 depicts the year-by-year progression of publications to date. Although the field is still in its early stages, this topic proves to be of growing interest among researchers as most publications included in the study were from 2021 and 2022, being nine each.

Table 1 depicts how frequently 4IR technologies were discussed in the papers and the impact they have on quality management in manufacturing respectively. Artificial Intelligence, big data and analytics, and cyber-physical systems were the most covered technologies, appearing 18 times apiece, followed by the Internet of Things (14 times), autonomous robotics (10 times), and machine learning (9 times). 3D printing, augmented reality and virtual reality, blockchain technology, and cloud computing were all mentioned 29 times. This clearly indicates 4IR technologies that have a significant impact on quality management techniques.

Table 1: Industry 4.0 elements and their impact on quality: summary of accepted papers

Industry 4.0 Features and Technologies	Impact on Quality Management Practices	Frequency	Cited Publications
Big Data and Analytics	• Improves quality of design • Improves quality of conformance • Improves performance of quality when used with AI • Influence predictive maintenance	18	[2], [3], [6]-[9], [12], [13], [15]-[17], [21]-[27]
Robotics	• Increased accuracy and efficiency • Real-time monitoring • Minimizes human intervention thereby improving safety • Standardization	10	[8]-[13], [16], [21], [23], [26]
Internet of Things	• Real-time monitoring and data collection • Predictive maintenance • Enhanced collaboration • Cost savings by reducing the risk of defects and equipment failure	14	[2], [3], [6], [8], [9], [12], [13], [15]-[17], [21], [23], [26], [27]
Cyber-Physical Systems	• Improved process control • Enhanced data analysis • Real-time monitoring • Increased efficiency • Customization	18	[2], [3], [6]-[9], [11]-[13], [15]-[17], [21], [23]-[27]
3D Printing	• Improved design and prototyping • Enhanced customization • Reduced production lead times	8	[3], [6], [13], [16], [17], [21], [23], [26]

Industry 4.0 Features and Technologies	Impact on Quality Management Practices	Frequency	Cited Publications
	• Improved sustainability by reducing waste		
Artificial Intelligence and Machine Learning	• Improved product design • Predictive maintenance • Enhanced collaboration • Improved sustainability by optimizing production processes	18, 9	[2], [3], [5], [8], [9], [11]-[13], [15]-[17], [21], [23]-[27]
Augmented and Virtual Reality	• Improved training • Enhanced collaboration for remote workers • Improved prototyping and testing • Improved visualization	7	[11], [12], [16], [17], [21], [23], [26]
Blockchain Technology	• Improved traceability • Enhanced transparency • Increased efficiency • Improved security • Improved collaboration	7	[9], [15]-[17], [21], [23], [26]
Cloud Computing	• Increased accessibility • Improved scalability • Improved sustainability	7	[9], [11], [16], [17], [21], [23], [26]

Figure 3 shows how frequently quality management practices were mentioned in the publications. Papers addressed process management the most (19 times), followed by customer focus and evidence-based decision-making (18 times each).

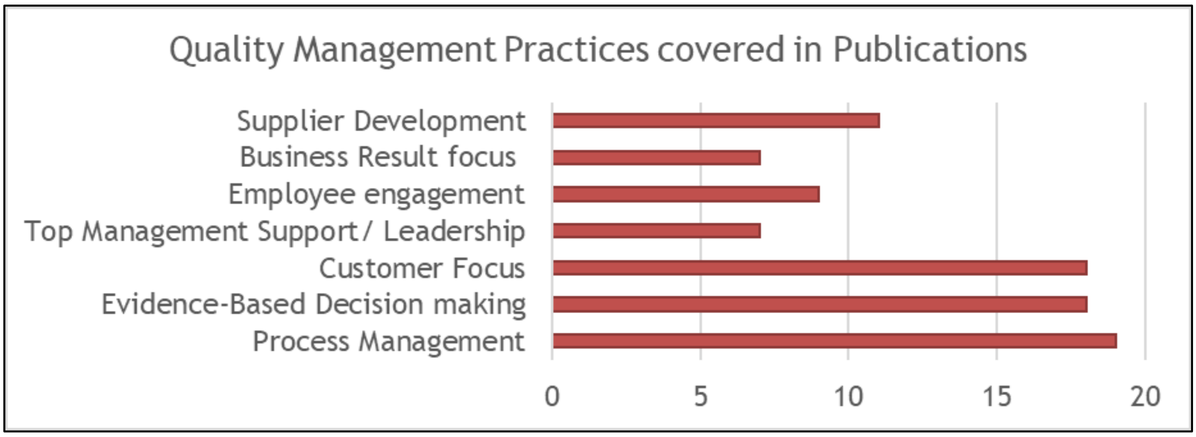

Figure 3: Appearance of quality management practices accepted for publication

Supplier development appeared 11 times. Employee engagement was mentioned 9 times, and top management support and business result focus were mentioned 7 times each.

Table 2: The main impact of Industry 4.0 technologies on quality management practices

QM Practices	Industry 4.0 Impact	ID	Frequency	Cited Publications
Process Management	Rapid process adjustments, processes are self-learning and correcting	P1	19	[1]-[9], [11]-[19], [21]-[26]
	Reduced downtime, advanced maintenance prognostication	P2	19	[1]-[9], [11]-[19], [21]-[24], [26]
	Shop floors are connected to the entire business units and to the customers	P3	18	[2]-[9], [11]-[19], [21], [22], [23], [26]
Evidence-Based Decision making	Enhanced data and insights encouraging improved decision making	I1	18	[2]-[15], [17]-[19], [21]-[23],[25]
	Improved defects prediction and proactiveness	I2	18	[2]-[9], [11]-[15], [17]-[19], [21]-[25]
	Early evidence can be used to correct or confirm decisions.	I3	18	[2]-[9], [11]-[15], [17]-[19], [21]-[25]
Customer Focus	Quick response due to machines and processes being self-learning.	C1	18	[2]-[4], [6]-[9],[11]-[16], [18]-[26]
	Personalised products are produced at a rapid rate	C2	18	[1]-[13], [21]-[26]
	Accurate market demand forecasting enabled by big data analytics and AI	C3	16	[2]-[4],[7]-[9],[11]-[16], [18], [19], [21]-[26]
Business Result Focus	A change-motivating environment	B1	8	[4], [9]-[12], [15], [16], [20], [26]
	Proactive dynamic interaction with market demands	B2	11	[4], [7], [9]-[13], [15], [16], [18], [19], [25], [26]
	Immediate re-configuration of production processes in response to improvement requests	B3	8	[4], [7], [9], [12], [13], [18], [25], [26]

QM Practices	Industry 4.0 Impact	ID	Frequency	Cited Publications
	Overall business efficiency	B4	11	[4], [5], [7], [9]-[13], [15], [16], [20], [25], [26]
Employee Engagement	Facilitating innovation and idea sharing through enhanced communication and collaboration.	E1	7	[10], [12], [13], [14], [16], [17], [20], [24], [26]
	Enhance/augment human intelligence by preserving prior knowledge and tailor-making career developments	E2	8	[7], [10], [12], [14], [16], [19], [20], [24]
	Transparency, traceability, and auditability are all improved.	E3	8	[10]-[14], [16] [17], [20], [24]
	Improves employee culture and transformation	E4	9	[10]-[17], [20], [24], [26]
Supplier Development	Complete supply chain transparency	S1	8	[11], [12], [15], [18], [19], [22], [24], [25]
	Easy-to-use tools for identifying and communicating with stakeholders	S2	7	[11], [12], [15], [18], [22], [24], [25]
	The opportunity to hire stakeholders based on their priorities	S3	5	[11], [12], [15], [18], [22]-[26]
	Stronger engagement with providers and partners to stimulate continual development	S4	5	[11], [12], [15], [18], [22]-[26]
Top Management Support/ Leadership	Effective resource allocation enabled by interconnectedness and integration	T1	7	[11]-[14], [16], [17], [20], [24]-[26]
	Increased coordination among all levels of the company	T2	6	[12], [13], [14], [16],[17], [20], [24]
	Comprehensive results evaluation enabled by big data and analytics	T3	5	[11], [12], [16], [17], [20], [24]
	Pre-production acceptance testing	QPC1	15	[1]-[6], [8], [9], [12],[13], [15],

QM Practices	Industry 4.0 Impact	ID	Frequency	Cited Publications
Quality Planning and Control				[16], [17], [19],[21]-[26]
	Failure detection before the final product is released	QPC2	16	[1], [2], [3], [5]-9], [11], [12], [13], [15], [16], [17], [19], [21]-[26]
	Quality control systems that are intelligent	QPC3	16	[1]-[9], [12], [13], [15], [16], [17], [19], [21]-[26]
	Real-time quality inspection	QPC4	17	[1-[6], [8], [9], [11]-[13], [15]-[17], [19], [21], [22], [24]-[26]

Table 2 presents the primary 28 themes or factors that indicate the effect of Industry 4.0 technologies on quality management practices, as identified during the data extraction process. The data was sorted, and the graph was created using Microsoft Excel. The results illustrate the frequency with which the code emerged during the data analysis.

As can be seen in Figure 4, P1-P3, I1-I3, C1-C3, and QPC1-QPC4 makeup 80% of the quality management elements that Industry 4.0 technologies greatly impact. Simply expressed, the majority of the publications discovered that integrating modern technologies with quality processes enhances process management (as a result of rapid process changes, self-learning and correcting processes, reduced downtime, advanced maintenance prediction, and shop floors connected to the entire business units and customers), evidence-based decision making (as a result of greater data and insights enabling better decision making, improved fault prediction and proactiveness, and early evidence that can be utilized to correct or confirm decisions), customer focus (owing to quicker responses due to self-learning machines and processes, the ability to develop customized products at a rapid rate, and precise forecasting of market demand), and quality planning and control the most. Companies aiming to implement Quality 4.0 should be aware that the impacts in the top 80% are the ones from which they are most likely to benefit.

Based on the data gathered from the chosen papers/articles and their interpretation, the research question posed above was addressed. The following subsections provide examples of the views of different researchers. Each study focused on technologies/elements of Industry 4.0 and various practices or techniques of the quality management field. The different technologies/elements and the different quality management practices covered in publications are indicated in Table 1 and Figure 3, respectively. The perspectives of researchers on the impact that 4IR features have on various quality management practices and methodologies are covered in the next section.

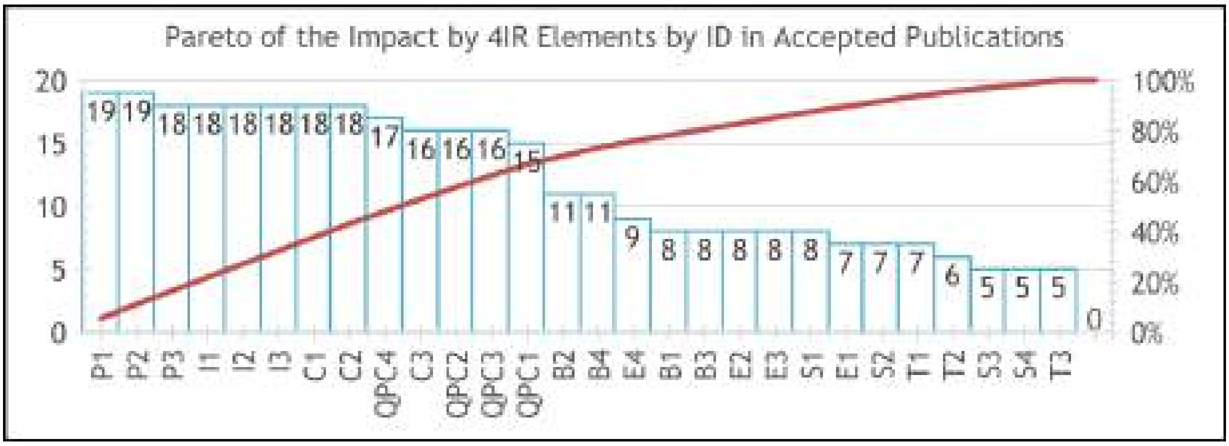

Figure 4: Pareto chart of the impact of 4IR elements by ID in accepted publications

5.1 Benefits associated with Quality 4.0 in traditional QM practices.

- **Evidence-based decision making**

According to Corti et al. [2], Maganga and Taifa [16], and Escobar et al. [21], sensors will make sure that manufacturing systems and processes are transparent, facilitating decision-making and ultimately meeting customer needs. Decision-making based on anything other than high-quality data is reactive, ineffective, and disconnected from reality [21].

Technologies from the Industry 4.0 movement promise to improve quality at every level of the production process, including information needed to plan, maximize, and control. Real-time data transmission and reception increase both the quality and transparency of information.

Prescriptive data analysis algorithms may be utilized to improve the quality of planning, according to Saihi et al. [22]. They further stated that by offering design, performance, and conformance quality measures, these analytics enhance data-informed decision-making.

- **Process management**

The use of big data and analytics can assist in resolving problems related to process efficiency and quality. Companies can move towards proactive, assertive, and intelligent decision-making by evaluating the information they have available. Decision-makers are receiving an increasing amount of data from machines that are embedded with sensors thanks to analytics acting as a new optimizer [2], [21], [22]. Companies should arrange their production processes based on analytics to create smart factories, allowing for better informed and real-time decision-making across the whole value chain [2], [8].

Process monitoring, according to Dias et al. [23], can be carried out by humans or by machine self-correction, allowing for rapid process adjustments. Furthermore, the evidence suggests that increasing automation in the manufacturing process will improve process quality [11], [23].

Shop floors are connected to all the business units and the customers, thanks to the integration and interconnectivity capabilities afforded by Industry 4.0 technologies. breaking down communication boundaries and allowing the process to be redesigned to eliminate faults before the end product is finalized [24], [25], [26].

Cyber-physical systems will create simulations of various production scenarios, using dynamic production variables to determine the optimal scenario before implementation. As a result, the production regime's design and testing will take less time, and the process will be more adaptable. This will result in less downtime on the shop floor [25], [27], [28].

- **Leadership support**

According to Sader et al. [29], big data, integration, and interconnection capabilities enabled by Industry 4.0 help senior management to execute their jobs effectively by improving coordination and collaboration among various levels of management, hence increasing the company's capacity to deliver distinct quality results. Information flow throughout the manufacturing supply chain is significantly improved by Industry 4.0. According to the evidence [28], [29, [30], an improved information flow integrates business processes and makes it possible for ERP systems to improve factory management. Furthermore, the supply of good data to management provides management with information to enable effective decision-making and the provision of the necessary staff support.

- **Business results focus**

Stasiak-Betlejewska et al. [31] claim that automated machines and processes will increase productivity, accuracy, and flexibility through the efficient real-time exchange of information during the manufacturing process. This strategy will make businesses that pay attention to the market’s current needs more competitive [23], [31]. Big data analytics can be used by businesses to gather, analyse and predict future consumer needs based on historical user data [11], [29]. Customer satisfaction is known to be a great catalyst for business growth.

Additionally, according to Stasiak-Betlejewska et al. [31], a business that integrates 4IR technology into its quality management methods can anticipate increased efficiency and cost savings as a result of real-time quality control that is modular, adaptable, and tailored to the user's manufacturing concept, real-time production planning, and overall business integration.

- **Customer Focus**

Industry 4.0 technologies may offer customization capabilities from time to time, according to Sader et al. [28], [29], [30]. Big data analytics, one of the 4IR enablers, will gather information from embedded sensors and use it to forecast trends and future needs, enabling improved product designs, ensuring that customers are satisfied, and preserving the organization's competitive advantage.

Customer satisfaction will be made possible by 3D printing, according to several researchers [30], [32], [33]. They contend that it enables customers to perfectly personalize and alter proposed designs, enabling enterprises to switch from mass to personalized manufacturing. Customers can alter designs mid-production and add personalization because of end-to-end integration, which keeps them informed about the production process and gives them a feedback loop that enables them to share their user experience with producers for future improvements.

According to Zheng et al. [34], the adoption of an Internet of Things platform can assist in identifying critical defect-related data, enabling quicker and greater quality defect avoidance as well as cost savings. As a result, the primary application of the Internet of Things in quality management is the early identification of problems in produced goods [35].

- **Employee Focus**

Sader et al. [29] claim that in a good quality management system (QMS), employees at all organizational levels are actively involved in enhancing the company's abilities to create and deliver value to customers. In this regard, Industry 4.0 will facilitate employee collaboration and communication by offering a choice of employee engagement and human resource management strategies that provide benefits from connectivity and social media [36].

Additionally, 4IR will promote transformation by highlighting individual contributions to the expansion of the company. When a QMS is digitized, digital technology and quality tools, processes, and systems are linked, claim Dias et al. [23] and Ghobakhloo [36], ensuring that employees are cognisant of their daily tasks. This function, which is connected to improving training and learning, boosts productivity, efficiency, and employee engagement.

Furthermore, according to a study by Dalmarco et al. [37], collaborative robotics enable workers to carry out difficult tasks that call for intuitive judgment while handing off laborious or boring tasks to automated systems. Collaborative robotics is therefore viewed as an addition to human activity in circumstances where labor is scarce, there is a lack of production capacity or there is low efficiency and performance in repetitive jobs.

Lastly, researchers believe that process automation and simplification, as well as the improvement to decision-making they provide, can greatly boost the effectiveness of human resources [23], [29], [37]. To customize career development or learning programs to individual employees' behavior, experience, abilities, personality, and learning habits, managers can, for instance, use AI and data analytics to identify significant patterns in information provided by employees.

- **Supplier development**

According to Sader et al. [29], industry 4.0's total integration makes it feasible for stakeholders to communicate effectively with one another. Since they are involved in the production process, suppliers are very sensitive to customer expectations.

Blockchain technology can also support efforts to cultivate suppliers. On the blockchain network, the money used to fund a supplier development program can be tracked [38], [39]. The types of knowledge that are exchanged and the kinds of organizational assistance that providers get can both be tracked using a smart contract. The data collected can be used to evaluate the efficacy of supplier development initiatives.

It is possible to evaluate performance before and after implementing a blockchain training program [40], [41], [42]. Smart contracts can be used by businesses to guarantee that they only do business with suppliers who take part in supplier development programs. Suppliers can be selected using this technique.

Blockchain enables complete supply chain transparency, thus enabling businesses to monitor their business practices. End-to-end openness in supply chains has been touted as the latest answer to the supply chain issue, which is more critical than ever, given concerns about legitimacy [23], [28], [29], [42]

- **Quality planning and quality control**

Collecting and integrating non-production data such as customer experience, customer usage, installation and service, and recycling data into the design stages of new concepts to assure product enhancements and zero errors [11]. This guarantees that planning for any new product also ensures quality.

Process monitoring quality makes certain that errors are found, and the information is saved and made available when needed [11], [23], [37]. Data obtained during traditional quality control and inspections are frequently lost, which makes it more difficult to adapt to the automation process. Traditional statistical process control included drawbacks such as not completing all measurements for a production process on time and, due to the delay in obtaining the measurements, defective products being fully manufactured before the anomaly was detected [1], [2], [4], [11].

According to Chouchene et al. [5], Stojanovic et al. [7], Chiarini [11], and Carvalho et al. [43], the ability to visually identify anomalies is one of the most important manufacturing challenges requiring the use of Industry 4.0-led inspection systems. Manual inspection depends greatly on the working environment, and the operator's perspective and efficiency, all of which are frequently impacted by pressure, weariness, and degree of passion [11], [23]. Additionally, visual control is time-consuming and typically yields unsatisfactory corrective results because it is frequently random. Small faults that are invisible to the naked eye are missed but can be found easily in the 4.0 era.

5.2 Challenges associated with Quality 4.0 in traditional QM practices.

While Quality 4.0 has the potential to improve quality management in various ways, some challenges need to be addressed. Some of these challenges are included in the table below.

Table 3: Challenges of Quality 4.0

QM Practices	Challenges posed on each element by Quality 4.0	Consequences	Publications
Process management	The effective integration of new technologies with existing processes and legacy systems and ensuring that employees are trained to use them seamlessly and effectively.	Integration issues with existing systems and processes could lead to disruption of operations and decreased efficiency.	[1]-[9], [11]-[19], [21]-[26]
Customer focus	Data privacy concerns while collecting customer data and ensuring the accuracy and reliability of the collected data.	Data inaccuracies and errors could compromise product quality, customer satisfaction, and overall business performance.	[1]-[16], [18]-[26]
Evidence-based decision making	Quality 4.0 generates vast amounts of data. Managing and analyzing this data can be a significant challenge and ensuring the accuracy and reliability of the data collected is a challenge.	The decisions made based on unreliable or inaccurate data could result in poor business performance and can also harm the reputation of the company. Moreover, decision-makers might make decisions based on incorrect data, leading to incorrect conclusions, and taking the company in the wrong direction.	[2]-[9], [11]-[15], [17]-[19], [21]-[25]
Business result focus	Ensuring the accuracy and reliability of the data collected, as	Data privacy and security breaches could result in legal and	[4], [7], [9] [13], [15], [16], [18]-

QM Practices	Challenges posed on each element by Quality 4.0	Consequences	Publications
	well as addressing cybersecurity concerns.	reputational damages for the organization.	[20], [25], [26]
Employee engagement	Employee engagement requires significant investment in training and development, and addressing concerns related to job displacement.	Employees may not be comfortable using the new technologies, leading to decreased engagement and productivity. Lack of training and development opportunities for employees may lead to skills gaps and hinder organizational growth and innovation. Job displacement concerns may lead to employee dissatisfaction, low morale, and increased turnover rates.	[10]-[17], [20], [24], [26]
Supplier development	Ensuring that suppliers are comfortable sharing data and ensuring that the data collected is accurate and reliable.	Supplier discomfort with data sharing could hinder collaboration and innovation, leading to missed opportunities for business growth.	[11], [12], [15], [18], [22]-[26]
Top management support	Ensuring that top management is comfortable using these technologies and is well-trained to offer support to the rest of the organization.	Top management's discomfort with the new technologies could lead to resistance to change, resulting in decreased adoption rates and missed opportunities for process improvement and cost savings.	[11]-[14], [16], [17], [20], [24]-[26]

6 CONCLUSION

This systematic literature review concludes that there has been a significant increase in publications on the impact of 4IR technologies on quality management practices in the manufacturing sector. Although Quality 4.0 implementation will improve quality management procedures holistically, they will mostly improve evidence-based decision-making, process management, and customer focus. However, challenges such as data accuracy, cybersecurity, employee training, and integrating technologies into existing processes and systems must be addressed to yield optimum results. The study serves as a guide for researchers and practitioners looking to implement Quality 4.0 in manufacturing.

The consensus in the literature as presented by this systematic literature review encourages organizations, even those in developing countries like South Africa, to transition to Quality 4.0 to improve their manufacturing practices and reduce the impact that poor quality has placed on their products and brand image.

Future research should broaden the scope to encompass the impact on other practices and explore effective ways of addressing challenges related to Quality 4.0 to optimize benefits.

ABSTRACT

Cost of quality is an aspect of quality management that measures the financial impact of quality on an organization. This paper presents a semi-systematic review of significant CoPQ incidents in the South African automotive industry over the past decade. The purpose is to identify patterns and similarities in these incidents to facilitate learning, prevent their recurrence and maintain competitiveness in the South African economy. Using a cause-and-effect diagram, the review highlights the root causes contributing to CoPQ incidents, such as inadequate quality control, ambiguous supply chain processes, and a lack of customer focus. Based on the findings, the study recommends investing in Quality 4.0 initiatives as a solution. These initiatives can improve real-time quality control, prioritize customer-centric quality management, and provide opportunities for employee development. The study contributes to the current understanding of CoQ and offers recommendations for South African organizations to enhance their quality management practices ensuring global competitiveness.

Keywords: CoPQ in South Africa, Cost of Quality, Manufacturing, Quality 4.0, Quality Control

1 INTRODUCTION

The South African government's vision of expanding employment opportunities from 10 million in 2010 to 24 million by 2030 highlighted the labour-intensive manufacturing industry as a significant generator of job opportunities [1]. South Africa's manufacturing sector was thus designated as the country's economic backbone [1]-[3], currently contributing 12% of the country's GDP. As the country's leading manufacturing sub-sector, the automotive industry employs over 11000 people and contributes significantly to South Africa's economy [2], [4], [5]. However, the industry faces various challenges, including inconsistent power supply, limited local demand and intense competition from foreign firms [1], [2]. In addition to these challenges, the industry has been grappling with cost of poor quality (CoPQ) incidents that have emerged as another critical factor affecting its performance.

CoQ incidents, such as product recalls and quality failures, not only result in direct costs for manufacturers but also reduce output and tarnish the reputation of companies, causing clients to turn to alternative brands [6], [7]. In recent years, South Africa has experienced several high-profile CoPQ incidents in various industries, including automotive, food and other consumer goods. In the last decade, the South African automotive industry was plagued by three significant CoPQ incidents, as reported by several media outlets [4], [8], [9], [10]. These incidents have raised concerns about quality control and safety standards in South African automotive manufacturing, thus undermining public confidence in locally produced products, resulting in decreased contributions to the country's GDP.

As Figure 1 illustrates, the contribution of the South African automotive industry to GDP has declined significantly from 7% in 2012 to 4.3% in 2022.

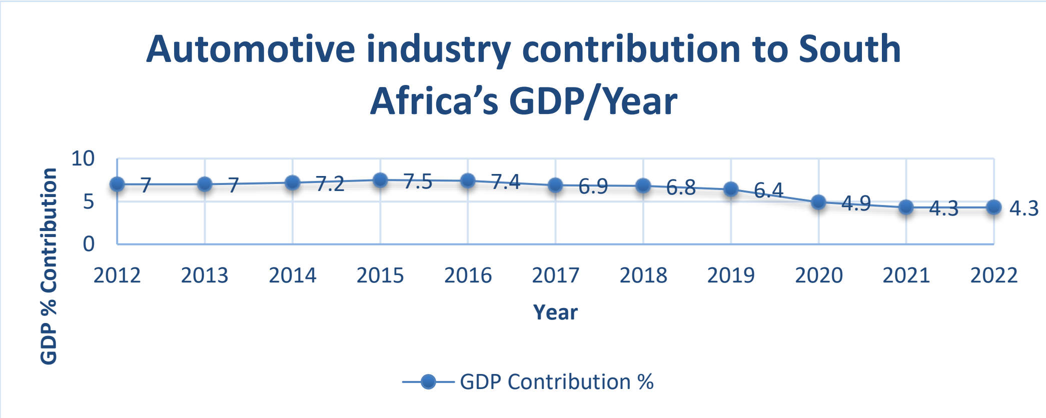

Figure 1: Automotive industry contribution to South Africa's GDP/Year [1], [4], [11]

In light of these challenges, this critical reflection aims to provide valuable insights into some of the prominent CoPQ incidents that have occurred in the past decade, focusing on three leading vehicle manufacturers, that have been widely reported in literature and by respected newspapers, such as Business Day, City Press, Daily Maverick and The New Age. The study systematically identifies trends, repetitions and similarities in these incidents, to promote avoidance and ensure that the industry remains competitive. By examining these incidents, this study seeks to contribute to the body of knowledge on CoPQ incidents in the South African automotive industry, providing a basis for further research and discussion on this critical issue.

2 THEORETICAL BACKGROUND

2.1 Cost of Quality

The concept of Cost of Quality (CoQ) is widely used by organizations as a tool to measure the financial cost incurred due to the production of products or provision of services. Cost of Quality (CoQ) is a subset of quality management (QM) [6]. Quality management includes all the activities related to ensuring that a product or service meets or exceeds customer expectations.

Activities such as quality planning, quality assurance, quality control and continuous improvement form part of traditional QM tasks. CoQ is one of the tools used in quality management to measure the financial costs of producing products or services and to identify ways to reduce those costs [7], [12]. The concept of CoQ was first introduced by Armand V. Feigenbaum in the 1950s and later, in the 1970s, Philip B. Crosby popularized it and introduced the concept of "zero defects”. Another pioneer of CoQ is Genichi Taguchi, who developed the Taguchi method of quality control in the 1980s.

According to Surange et al. [13], the cost of quality refers to the additional expenses incurred in producing a product or service caused by errors, defects and/or poor performance. In essence, every time a task or process is repeated to rectify errors, the cost of quality rises [13], [14], [15]. CoQ encompasses all costs associated with quality, including prevention costs, appraisal costs, and internal and external failure costs, as shown in Figure 2.

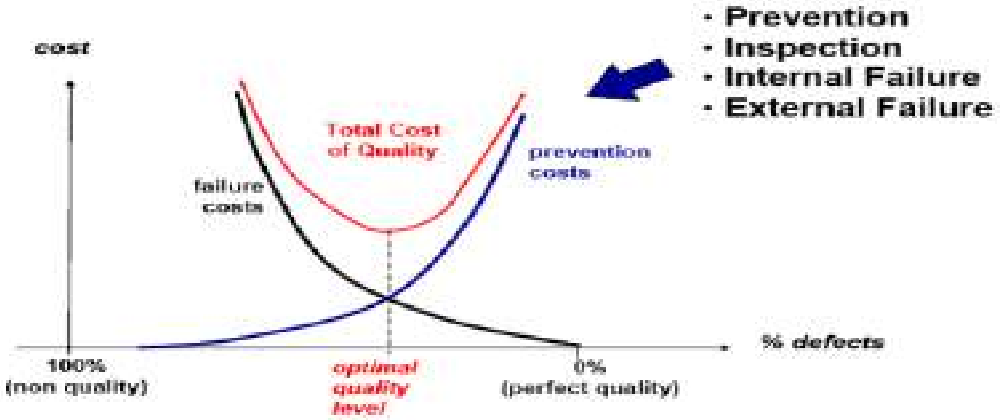

Figure 2: Cost of Quality [7], [13]

According to Makhanya et al. [16], cost of quality is a sum of cost of good quality (CoGQ) and cost of poor quality (CoPQ), as seen on Equation (1). CoGQ comprises all the costs associated with ensuring quality, i.e., prevention and appraisal costs as seen on Equation (2).

$$Cost\ of\ Quality\ = Cost\ of\ Good\ Quality + Cost\ of\ Poor\ Quality \quad \textbf{(1)}$$

$$Cost\ of\ Good\ Quality = Prevention\ Cost + Appraisal\ Costs \quad \textbf{(2)}$$

$$Cost\ of\ Poor\ Quality\ = Internal\ Failure\ Costs + External\ Failure\ Costs \quad \textbf{(3)}$$

Prevention costs refer to the costs associated with preventing defects from occurring, such as training and education, process improvement, and research and development [16]. Appraisal costs are incurred when products and services undergo inspection and testing to ensure compliance with quality standards. On the other hand, CoPQ is a sum of all the costs associated with internal and external failures as seen on Equation (3). Internal failure costs encompass the expenses related to identifying defects before the customer receives the product, while external failure costs encompass the expenses incurred when defects are discovered by the customer after they have received the product [7], [17], [18].

Measuring CoQ can help organizations identify and eliminate the sources of defects and ultimately improve the quality of their product or service [17], [18]. Reducing this cost can lead to increased customer satisfaction, increased market share and reduced costs due to fewer defects, which in turn ensures that the business stays competitive with increased profit margins. CoPQ external failure incidents can have severe consequences for manufacturing organizations, including financial loss, damage to reputation and image, increased costs resulting from rework, repair and warranty claims, and negative impacts on the economy, even in highly developed economies [12]. This paper focuses on external failures as identified by consumers.

3 RESEARCH OBJECTIVES

Despite being a leading manufacturing country in Africa [1], [2], South Africa has had several manufacturing problems over the past decade. It is crucial to reflect upon these errors, as they provide valuable lessons from which we can learn and improve. Therefore, the objective of this study is to systematically examine existing literature to explore the implications, root causes and overall consequences of quality-related incidents to organizations.

4 METHOD

The research question, which outlines the objective of the study and the researchers' goals, is directly related to the methodology because it defines the process employed to answer the question [16]. This study explores poor quality incidents and quality failures in the South African automotive industry to determine if there is a pattern to and any similarities between these incidents. By so doing, the researchers hope to identify lessons that can be learned, thus preventing recurrences. If such lessons can be learned by South African manufacturers, the researchers believe that the competitiveness of the South African economy can be maintained. The researchers employed a semi-systematic review methodology to enable a comprehensive examination of various research traditions and their implications. A semi-systematic literature review follows a structured process to identify and include relevant studies but may not adhere to all the rigorous methodologies of a fully systematic review. Researchers may opt for this kind of a review if the area is not yet widely researched. By synthesizing the findings using a meta-narrative, this study ensures transparency and enables readers to assess the reasonableness of the arguments.

4.1 Time span

This study spans a 10-year period.

4.2 Research terms and databases

The primary search terms utilized in this study were "South African Automotive" AND "Cost of poor Quality" AND "Quality Incidents" AND "Product Recalls". In addition, the study included articles that concentrated on "Product Recalls" and "South African Manufacturing". The research utilized official government sites, reputable media houses, Scopus, Emerald and IEEE Xplore as databases for collecting literature.

4.3 Inclusion and exclusion criteria

The studies included in this research had to meet specific criteria to ensure their reliability and credibility: they had to be published by reliable sources, such as government official reports and reputable databases, and the studies had to cover incidents of poor quality in the South African automotive industry. Studies that did not contain enough information to fulfil the research objectives were omitted.

4.4 Data analysis

Both quantitative and qualitative techniques were used to analyse the text. In this case, the qualitative techniques involved identifying and grouping themes or patterns that emerged. Data from the grouped themes was summarized and synthesized using quantitative methods.

5 FINDINGS AND DISCUSSIONS

As can be seen in Figure 3, the number of publications on quality incidents in the South African automotive industry has increased steadily in recent years. Although customers had been laying complains regarding poor quality experienced in their automobiles, the topic only gained traction recently when manufacturers began recalling faulty vehicles. In 2013 and 2015 there was only one publication each year, but the number of publications increased to a total of 10 in the period, 2017 to 2018.

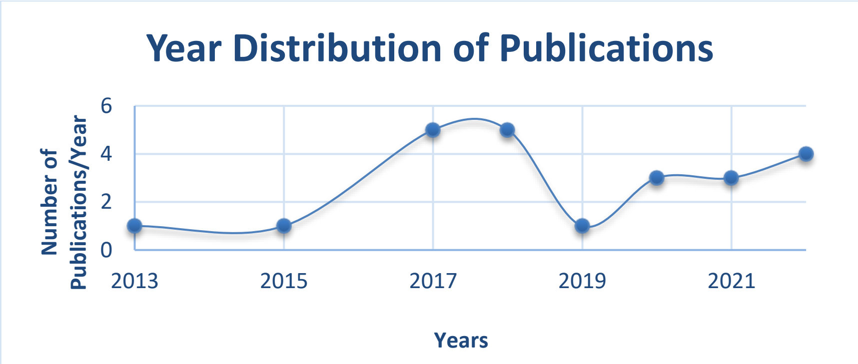

Figure 3: Year-to-year distribution of publications on quality incidents

Although the number of publications dropped in 2019, it picked up again in 2020 and 2021, with three publications in each year, and four publications in 2022. This trend indicates that during this decade, there had been publications covering customer dissatisfaction since 2013, although product recalls only took place later.

Through the semi-systematic literature review, several prominent cost of poor quality (CoPQ) incidents in the South African automotive industry were identified and are presented in Table 1. Each incident had its unique primary cause, with Mercedes-Benz facing brake defects, Toyota dealing with faulty airbag inflators and Ford experiencing vehicle fires.

Table 1: Notable CoPQ incidents in the South African automotive industry

Organization	Model Recalled	CoQ	Year of Recall	Publications
Mercedes-Benz	ML, GL and R-class series	Brake defects	2022	[4], [5], [10], [19]-[24]
Toyota South Africa Motors Recalls	Corolla, RunX, Yaris, Hilux and Fortuner	Faulty airbag inflators	2018	[4], [9], [20], [21], [25]-[28]
Ford Kuga recall	Kuga	Vehicle catching fire	2017	[4], [10], [20], [22]-[24], [27]-[30]

The following section delves into detailed case studies of these incidents, examining their primary causes, possible root causes and the implications they had on the automotive industry in South Africa.

Case 1: Mercedes-Benz Brake Defect Recall [4], [5], [10], [19], [20], [21], [22], [23], [24]

In April 2022, Mercedes-Benz South Africa issued a recall of 13 159 vehicles produced and sold between 2006 and 2019 [10], [24] due to potential brake failure that could result from rusting of the joins of the brake booster housing. The rusting occurred as a result of moisture accumulating in the rubber sleeve that covers the housing, either due to prolonged exposure to water or over time. If not addressed, this defect could cause the brake pedal to disconnect from the system, resulting in compromised braking performance. The National Consumer Commission raised concerns about this issue [22], [23]. The announcement of the recall led to the financial cost of recalling 13,159 vehicles (not published yet), a drop in the share price of more than 4% and reputational damage [10], [22].

Primary cause:

Rusting at the joining points of the brake booster housing

Possible secondary causes:

- **Inadequate quality control**: The first possible secondary cause of the brake defect was inadequate quality control measures during the manufacturing process. The defect was caused by advanced corrosion of the brake booster [10], [22], [24], which indicates that the part may not have been properly treated or coated to prevent corrosion. This suggests that there were gaps in the company's quality control processes, which allowed defective parts to enter the production process.
- **Design flaw**: The Acting National Consumer Commissioner Thezi Mabuza alerted the public that this incident was caused by a flaw in the design of the brake booster [22], [23]. It is possible that the potential for corrosion was not consider sufficiently in the design or the design did not provide sufficient measures to prevent corrosion. This may have caused the brake booster to become more vulnerable to corrosion and ultimate failure.
- **Lack of customer focus**: The manufacturer delayed the recalls since the first complaint in 2006, which demonstrates either a lack of customer focus and/or lack of proper feedback loops from customers, and a lack of accountability, leading to the manufacturer missing the public customer complaints regarding this issue [10], [22].

Case 2: Cost of Quality Incident at Toyota South Africa Motors [4], [9], [20], [21], [25], [26], [27], [28]

In January 2018, Toyota South Africa Motors (TSAM) made an announcement regarding the recall of over 700 000 vehicles due to safety concerns related to their airbags. The purpose of the recall was to replace front airbag inflators manufactured by Takata. These inflators had the potential to burst due to moisture intrusion, thus posing a safety risk. According to Mzolisi Witbooi, the PR Manager for the company, Toyota, along with other car manufacturers around the world, was conducting a recall of vehicles with potentially faulty Takata airbag inflators [9], [25], [26].

This issue had affected almost 100 million vehicles across various brands worldwide. In South Africa, Toyota had identified 730 000 vehicles that were affected by this recall. However, according to an Eyewitness News article in 2018 [9], this was not the first instance of Toyota recalling vehicles due to airbag issues. In 2016, more than five million cars with the same problem were recalled globally. The total cost of this incident was stipulated to be R5 500 000 000 [18]. Before the announcement of the recall, Toyota Motor Corporation's share price was trading at around R877,49 per share on the Tokyo Stock Exchange. Following the announcement of the recall, the share price initially dropped by around 1% to 2% [9], [25], [26], [31].

Primary Cause:

Faulty airbag inflators produced by Takata.

Possible Secondary Causes:

- The secondary causes of the incident were **poor supplier selection** and **inadequate quality control**. TSAM had chosen Takata as a supplier for the airbag inflators without fully evaluating their manufacturing processes, quality control procedures and history. Takata had a history of quality control issues and product recalls [9], [25], [26]. Additionally, TSAM's quality control processes were inadequate, as they did not detect the issue with the airbag inflators during the initial quality checks.

- **Design Flaw:** Another possible secondary cause could have been a design flaw. The airbag inflators were designed to use ammonium nitrate as a propellant, which is a cheaper alternative to other propellants [9], [26]. However, the design was flawed as it did not prevent the potential intrusion of moisture, which caused the inflators to rupture, thus posing a safety risk to drivers and passengers [9].
- **A lack of customer focus**: This could have been a possible cause of this CoQ incident. The company may have been more focused on cost savings and production efficiency than ensuring the safety of its customers. The fact that Takata had a history of quality control issues and product recalls suggests that the company may not have been proactive in identifying and addressing the issue before it became a significant safety concern [9]. The organization also took too long to issue recalls, further putting their customers in danger.

Case 3: Ford Kuga Recall [4], [10], [20], [22], [23], [24], [27], [28], [29], [30]

In January 2017, Ford conducted a recall of 4 556 Kuga 1.6-litre Ecoboost models manufactured between December 2012 and February 2014 for repairs. This recall was triggered by several reports of the company's utility vehicles catching fire. According to Ford SA, there was a potential risk of a B-pillar fire in the event of a frontal collision [32], [33]. This was attributed to the seatbelt pre-tensioner being activated, which could ignite the insulation material surrounding the pre-tensioner. Post investigation, the incidents were linked to a cooling system fault that could cause an oil leak and lead to engine fires. Ford's Kuga recall highlights the importance of maintaining high safety and quality standards during the production process [8], [32], [33].

The National Consumer Commission fined Ford for R35 000 000 for breaching the Consumer Protection Act (protects consumers against unlawful and unfair trade deals) and they also had to pay R227 800 000 to consumers for inconvenience during the recall. The total cost of repairs was not stipulated. At the time of the recall, Ford's share price was trading around R218.18 per share. Following the announcement of the recall, Ford's share price dropped by approximately 4% to R209.09 per share in the days after the news broke. The fires also led to injuries and a fatality [8], [32], [33].

Primary causes:

Defect in the vehicle's cooling system

Possible secondary causes:

- **Design flaw:** One secondary cause of the Kuga recall was a design flaw in the cooling system, which allowed oil to leak and potentially ignite a fire in the engine compartment [8], [12], [32], [33]. The flaw likely originated during the design and engineering phase of the Kuga, where inadequate attention may have been paid to the safety and functionality of the cooling system. To attest to this, Mr A Williams admitted that the cooling system's inability to function in hot climates (South African climate) was due to a design defect.
- **Inadequate testing and quality control:** Another possible cause of the Kuga recall was inadequate testing during the production process. The faulty cooling system should have been identified during testing and addressed before the vehicles were released on the market [32], [33]. Inadequate testing may have been due to insufficient resources, time constraints, or a failure to prioritize safety and quality control.
- **Poor communication**: The delay in the recall of Kuga vehicles by Ford South Africa was partially caused by inadequate communication. Even though the quality control team

identified the faulty cooling system, the information may not have been properly shared with other departments such as marketing or customer service. This may have led to a delay in addressing the issue with the customers that had already bought the vehicle and implementing necessary changes to the product [24], [27], [28].

- **Slow response and lack of customer focus:** Another contributing factor to the delay in the Kuga recall was Ford South Africa's slow response to reports of engine fires. Although reports of Kuga engine fires surfaced in 2015, the recall was not initiated until 2017 [24], [27], [28]. This slow response might have been due to a lack of urgency or inadequate investigation into the issue. It also highlights the absence of efficient customer feedback loops, which could have provided early warnings of the problem. The company's failure to prioritize customer safety is evident. Had Ford prioritized customer safety, they might have discovered the cooling system fault earlier and taken measures to prevent fires from occurring. Instead, it required multiple vehicle fires and a recall before Ford identified the root cause of the problem and took corrective action [12].

The themes discovered throughout the review are listed in Table 2. This is done to identify common threats that South African manufacturing should learn from and solve in order to prevent a recurrence of these significant accidents.

Table 2: Similarities in root causes of the identified CoQ incidents

Possible root causes	Mercedes-Benz brake defect	Toyota South Africa Motors recalls	Ford Kuga recall
Ambiguous supply chain processes		✔	
Design flaw	✔	✔	✔
Inadequate testing and quality control	✔	✔	✔
Poor communication	✔		✔
Inadequate feed-back loops	✔	✔	✔
Slow response and lack of customer focus	✔	✔	✔

As laid out in the table, all three large corporations lacked customer focus because they neglected to carry out adequate testing and quality control, missed a design flaw and delayed recalling the defective vehicles (Mercedes-Benz recalled vehicles that had been manufactured 13 years previously, Toyota South Africa Motors 15 years previously and Ford 5 years previously), putting their valued customers lives at risk. The review also demonstrates that the policies are not stringent enough for manufacturers to fear producing defective products. According to Surange et al. and Makhanya et al. [13], [16], the cost of producing a defect free product is 10 times less than the cost of repairing a product immediately after production before it reaches the customer base, and the cost becomes 100 times more when it is recalled from the customer. This phenomenon is illustrated in Figure 4.

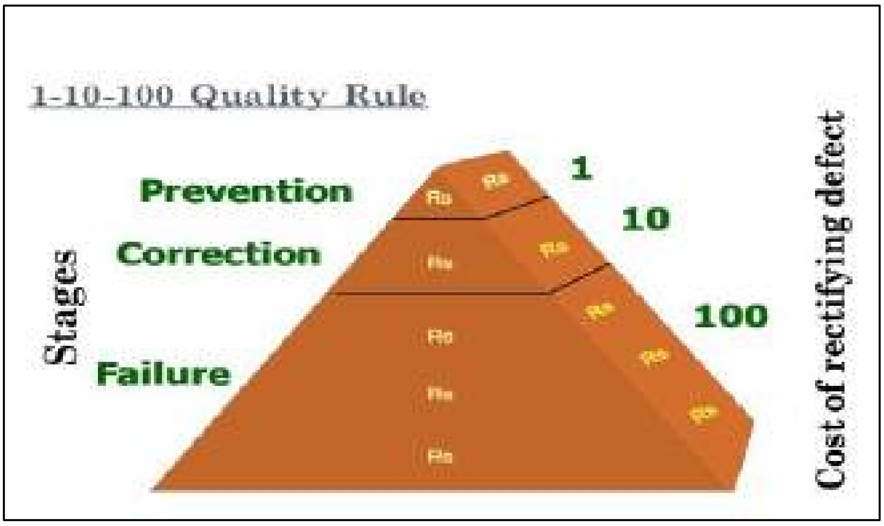

Figure 4: 1-10-100 Rule [13]

The results of the semi-systematic review also indicate that there are similarities in the implications that the three giant automobile manufacturers faced as a result of their respective recalls.

Table 3: Similarities in the implications of identified CoQ incidents

Impact	Mercedes-Benz brake defect [4], [5], [10], [19], [20], [21], [22], [23], [24]	Toyota South Africa Motors recalls [4], [9], [20], [21], [25], [26], [27], [28]	Ford Kuga recall [4], [10], [12], [20], [22], [23], [24], [27], [28], [29], [30]
Financial loss	✔	✔	✔
Market share drop	✔	✔	✔
Reputational damage	✔	✔	✔
Injuries/Fatalities	None reported	None reported	✔

All three experienced reputational damage, which is a significant issue in the automotive industry where consumer trust is essential. According to Mushavhanamadi and Xundu [12], Ford recalls caused customers to avoid other models with no known defects. The recalls also had financial implications, namely the cost of recalling vehicles and the drop in share price. The recalls also resulted in property damage, injuries and a fatality in the case of the Ford Kuga recall.

6 REFLECTIONS & RECOMMENDATIONS

The cause-and-effect diagram, Figure 5, highlights the prominent root causes of the CoPQ incidents in South Africa as identified through the review [8], [9], [10], [12], [21], [22], [23], [24], [25], [26], [32], [33], [34], [35], [36], [37]. This depicts the primary factors the manufacturing sector needs to work on to avoid the incidents from recurring.

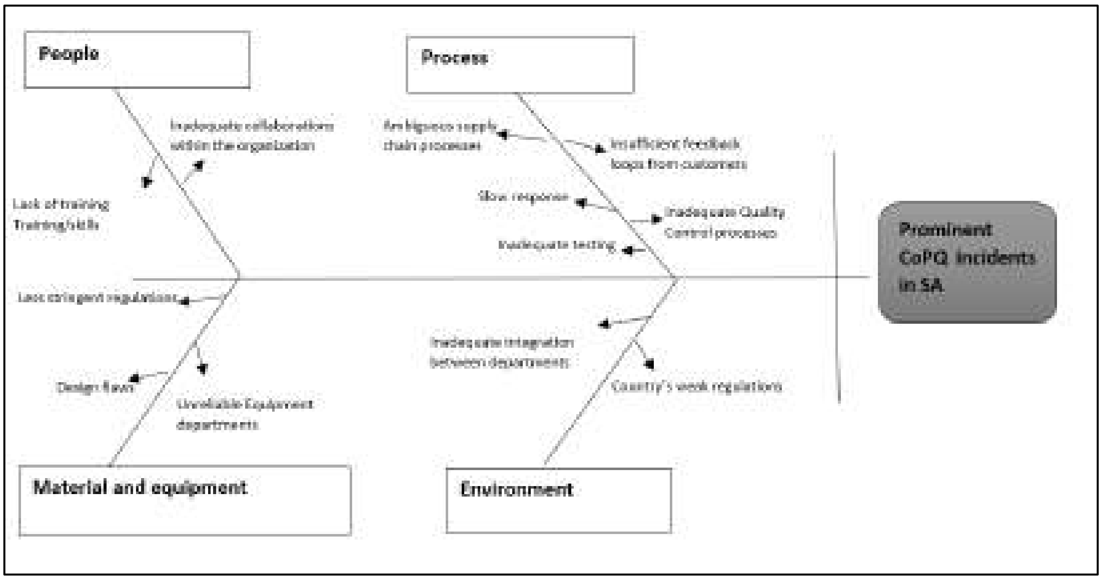

Figure 5: Ishikawa diagram for prominent root causes of CoPQ incidents in SA

To prevent such detrimental incidents in the future and save the future of South African manufacturing, companies should implement a comprehensive quality control program that includes regular testing of raw materials, components, and finished products. Companies should also review their supply chain processes to ensure that all suppliers adhere to strict quality standards and further improve collaboration with suppliers to ensure that all raw materials meet strict quality standards. Additionally, companies should improve their communication with regulators, customers, and other stakeholders to ensure timely and accurate reporting of any defects or issues, ensure transparency and build trust.

Additionally, manufacturers should invest in continuous improvement initiatives to identify and eliminate potential quality issues before they become significant problems. Such improvements include adopting Quality 4.0 into their legacy production processes. Quality 4.0 is a phenomenon of integrating Industry 4.0 technologies into traditional quality management practices [38], [39].

Industry 4.0 technologies like big data analytics, artificial intelligence, augmented reality, virtual reality, 3D printing, the internet of things, blockchain technology, and cyber-physical systems can revolutionize quality management practices by streamlining operations, automating processes, and making informed decisions [38], [39]. These technologies can process and analyse large volumes of data in real time, create intelligent systems that make autonomous decisions, produce intricate shapes and designs more efficiently [40], [41], [42], facilitate communication and data exchange, ensure secure and transparent transaction recording and verification, and enable real-time monitoring and control of physical processes [43].

7 CONCLUSION

This study has identified several prominent incidents that occurred in SA over the last decade. Their causes included insufficient quality control, inadequate training and development, ambiguous supply chain processes and a lack of customer focus. The impact of these incidents was not only financial but also dented the brand reputation and, in one case, caused a death. To prevent such detrimental incidents in the future and save the future of South African manufacturing, this study recommends that companies implement a comprehensive quality control program that includes regular testing of raw materials and finished products, review their supply chain processes to ensure strict quality standards are adhered to, and improve communication with regulators, customers and other stakeholders. Moreover, investing in continuous improvement initiatives, including adopting Quality 4.0 technologies, can significantly improve quality management practices, streamline operations, automate processes and make more informed decisions. By implementing these recommendations, organizations can avoid CoQ incidents and improve their quality control processes, enhance their supply chain management, and create a culture of continuous improvement. The time is now for South African manufacturing to prioritize quality control and create a sustainable future.

Future research should focus on the implementation of Quality 4.0 in manufacturing to reduce cost of quality.

Table 4: Glossary of Terms

Acronym	Full Word	Meaning
CoQ	Cost of Quality	One of the quality management methods used to quantify the costs associated with producing quality goods or services and to find strategies for lowering those costs [6].
CoPQ	Cost of Poor Quality	All the costs incurred by an organization due to poor quality [7], [17], [18]. This may also include hidden costs such as reputational damage and loss in future sales.
CoGQ	Cost of Good Quality	The costs invested in maintaining and improving quality to prevent defects and quality-related issues [17], [18].
Industry 4.0	The fourth Industrial Revolution	A phrase used to characterize the present trend in manufacturing that includes automation, data exchange, and digital technologies, including cloud computing, cyber-physical systems, and the Internet of Things (IoT) [40], [41], [42].
Quality 4.0	Quality Management in the fourth Industrial Revolution	The application of advanced quality management techniques, data analytics, and digital technologies to ensure and enhance product and service quality in the context of Industry 4.0 [38], [39].

ABSTRACT

Industry 4.0 has revolutionised the way firms manufacture or render services. Firms are deploying digital technologies such as artificial intelligence et al. The postal sector is not unscathed by these sweeping winds of change and has experienced a sharp decline in traditional mail volumes resulting in the tumbling profits placing some designated postal operators on route to extinction. However, trailblazers such as Swiss Post have adopted industry 4.0 disruptive digital technologies and are postal champions from which those trailing behind could learn and aspire to be. This paper explores the construction of stock and flows from the causal loop diagram that defines the dynamic hypothesis in the context of postal digital transformation, and further explores the quantification of aggregate variables and subsequent mathematical expressions. The development of the SD model and quantification of variables provides a novel approach to resolving the challenge faced by Southern Africa Postal Sector.

Keywords: Causal loop diagrams, stock & flow diagrams, SD model

1 INTRODUCTION AND BACKGROUND

The digital age has provoked Postal services across the globe to expand their services well beyond the original service of the Designated Postal Operators (DPOs) which is the distribution of postal mail items. UPU [1] argues that although some DPOs in several countries across the world struggle with financial turmoil, there are DPOs that are effectively competing at an international level, and are financially sustainable. There have been prevalent moves towards digital technologies throughout the developing world, which in turn led to digitalisation across industries including the postal industry. UPU [2] suggests that societal composition is swiftly shifting and the digital age has driven changes in the way society consumes products and services. This shift has led to the progression of the client of the future with exceptional requirements and expectations that the postal sector ought to meet.

However, according to UPU [2], the majority of DPOs are poorly performing on the Integrated Index for Postal Development (2IPD). UPU [2] proposes that the measurement of multiple dynamics of postal development is a complex task, and theorises that to overcome this challenge. According to [3] 2IPD measures the performance of POs in the four vital dimensions of postal development are reliability, reach, relevance and resilience.

Figure 1 paints a picture of the calamity facing the postal sector in Southern Africa compared to the tier 1 countries that perform well on the 2IPD and result in the postal sector in South Africa posting losses in respective countries and leaving the State to bail out the loss making entities, a burden to the taxpayer. Figure 1 illustrates the low scores of Southern Africa as compared to the tier 1 countries led by Switzerland which has consistently scored 100 over 100 points since 2018. Since a picture worth a thousand words, Figure 1 depicts the problem at hand in Southern Africa at a glance.

2 LITERATURE REVIEW

2.1 System dynamics paradigm

Guller [1] proposes that high-level models are modest models intended at strengthening insights, and analysis of complex phenomena, communication, and decision-making. Fisher [2] argues that system dynamics models have limitless opportunities to act as “flight simulators” that decision-makers may use as a training environment to conduct research and comprehend the complexity of the environments they model. Management of digital transformations and, more specifically, the effects of digital business transformations are becoming progressively complicated in the current business environment where competition and technological revolutions are dynamic and change happens at a faster pace than before [3]. A system dynamic approach offers a holistic view of the postal digital dynamics that are at play in this complex environment and will provide regulators, governments, and posts with a novel tool to manage interventions (policies) that will improve the postal system performance in Southern Africa and lead towards a sustainable future.

2.2 System dynamics principles and fundamentals

Sterman [4] contends that more often, well-intentioned energies to resolve persistent difficulties create unforeseen side effects. Actions taken from decisions taken provoked unforeseen reactions. The result is policy resistance which can be defined as the propensity for interventions to be conquered by the response of the system to the intervention itself. System dynamics is better positioned to counter this blind spot that characterises human mental models that completely miss the mark due to the inability to see the whole.

Yearworth [5] notes that System Dynamics modelling arose from ground-breaking work at MIT in the 1950s by Jay Forrester. Richardson [6] notes Forrester in his ground-breaking article in the Harvard Business Review (Forrester, 1958) put forward an initial statement of the approach that would, in time, become known as system dynamics. Richardson [6] argues that Forrester (1958) fashioned the method on what were then four interesting advances: (a) Progress in computing technology (b) Growth and skill with computer simulation (c) Enhanced comprehension of strategic decision making, and (d) Advances in the comprehension of the role of feedback in complex systems. Richardson [6] notes that Forrester (1958) devised the four fundamentals of industrial dynamics:

- The concept of feedback systems.
- A familiarity with decision-making processes.
- The investigational model approach to complex systems.
- The digital computer simulates a plausible mathematical model.

Maldonado et al. [7] concur with [6] and suggest that system dynamics modelling has been advanced as an approach and technique to (a) Provoke such feedback loops to determine the main growth, balancing, and decay (stagnation) dynamics that drive the behaviour of socio-economic systems, (b) To inspire the system’s dynamic behaviour through the application of differential equations and (c) To examine and design improved policies that will result in enhanced system performance. Maldonado et al. [7] further propose that the modelling process in system dynamics is grounded on iteration between all five stages: (a) Problem articulation (b) Dynamic hypothesis (c) Model formulation (d) Model testing and validation, and (e) Policy analysis and design.

Sterman [8] contends that modelling is a feedback process and not a series of linear steps and that models undergo constantly iterative, persistent questioning, testing, and enhancement. Figure 2 depicts the modelling process; the initial purpose defines the limits and scope of the modelling application, and frames what could be learned from the process of modelling through feedback to streamline a basic comprehension of the problem and the aim of the modelling effort. Iteration can occur from any step to any other step (indicated by the interconnections in the centre of the diagram). In any modelling project, one will iterate through these steps many times.

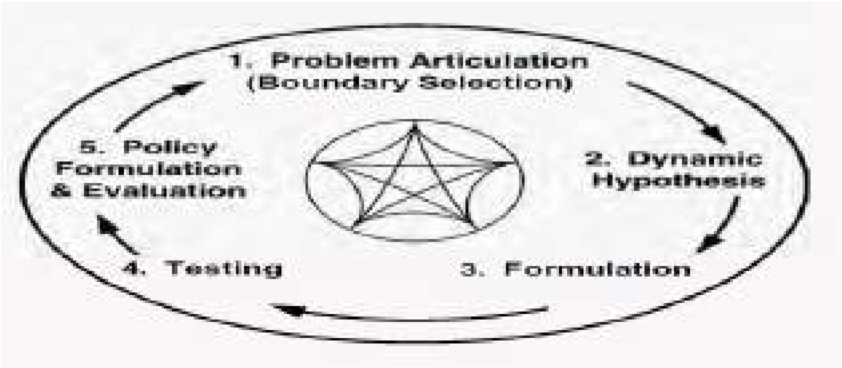

Figure 2: Modelling process

Sterman [8] hypothesises that the model is grounded by mental models and by information gathered from the real world. Stratagems, plans, structures, and decision guidelines in the real world can be considered and tested in the simulated world of the model. The experimentations conducted in the model feedback alter our mental models and lead to the design of novel stratagems, novel plans, novel structures, and novel decision rules. These novel policies are then implemented in the real world, and feedback about their effects leads to new insights in both our formal and mental models as depicted in Figure 2. Forrester [9] and Sterman [8] suggest that modelling is not a lone action that produces answers, but an enduring technique of incessant cycling between the virtual world of the model and the real world of action.

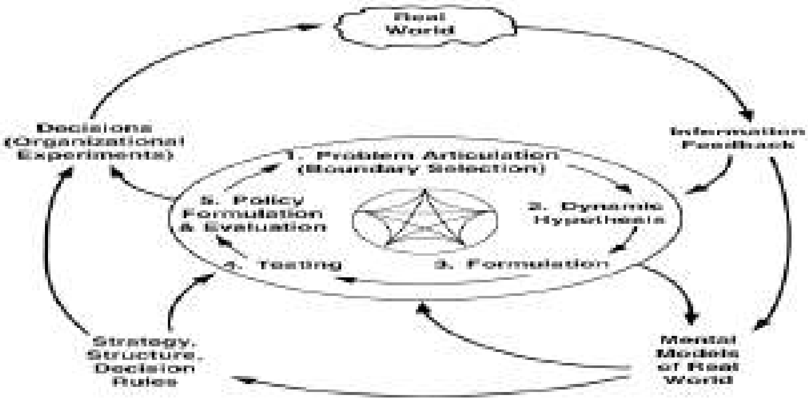

Figure 3: Modelling process embedded in dynamics of a system

2.2.1 Endogeneity and feedback

Richardson [6] suggests that the utmost prominent characteristics of the system dynamics method are indisputably stocks and flows, and feedback loops. These perceptible fundamentals stick out and grasp our attention. But it is important to note that feedback loops are a result of the endogenous point of view [6]. According to Richardson [6], Figure 4 demonstrates the idea. On the left is a depiction of a modest causal system, with causal elements extending outside the system boundary. The dynamics of variables A–E are engendered partially by the interplay among the elements within the system boundary but originate principally from variables P, Q, R, and S outside the boundary. The dynamics of this system are engendered exogenously by forces outside the system boundary.

Richardson [6] on the right is an endogenous view, in which the dynamics of variables A–E are engendered exclusively from the interplay among the variables, inside the system boundary.

Considering an endogenous point of view triggers causal influences to form loops, without loops, all causal influences would point to dynamic forces external to the system boundary. Feedback loops thus enable the endogenous point of view and give it structure [6]. Sterman [8] proposes that system dynamics attempts to discover endogenous explanations for phenomena. The word “endogenous” implies “emerging from within.” An endogenous theory engenders the dynamics of a system through the interplay of the variables denoted in the model.

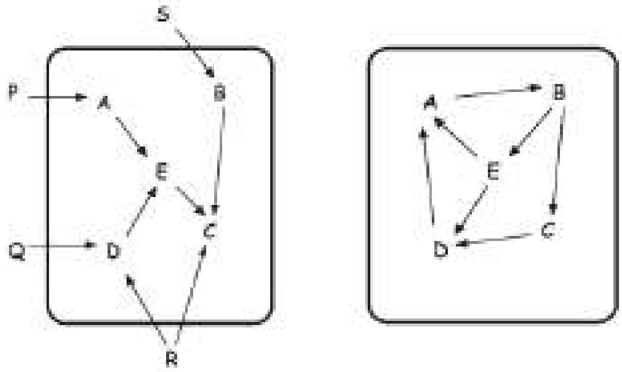

Figure 4: Left: Exogenous view of system structure; causality traces to external influences outside the system boundary. Right: Endogenous view; causality remains within the system boundary; causal loops (feedback)

2.2.2 Causal loop diagrams

Morecroft [10] postulates that a causal loop diagram is a schematic tool for systems thinking researchers, such diagrams illustrate the cause-and-effect relations and feedback processes. Haraldsson [11] suggests that CLDs (Causal Loop Diagrams) pronounce reality through interconnections amongst variables and how they produce a dynamic circular effect. According to Haraldsson et al. [12], CLDs are a means for methodically detecting, examining and communicating feedback loop structures. It is systematic thinking and enables the communication of complex information into a simplified circular loop feedback structure. CLD is a tool that promotes continuous thinking [12].

Sterman [8] proposes that Causal Loop Diagrams (CLDs) are agile and valuable tools for schematising the feedback structure of systems in any realm. Causal diagrams are sketches that illustrate the causal interconnectedness between variables with arrows from a cause to an effect. Figure 4 abridges the explanations of the interconnectedness of polarity. Sterman [8] further notes that a causal diagram entails variables' interconnectedness through arrows representing the causal influences amongst the variable with the significant feedback loops identified in the diagram. Delgado-Maciel et al. [14] suggest that CLD uses diagrams to classify feedback loops. In this diagram, an arrow signifies the causal interconnectedness between some variables.

2.2.3 Stocks and flow diagrams

Iandolo [15] argues that System Dynamics (SD) models can be evaluated through simulation, which is conceivable after the creation of a Stock and Flows Diagram (SFD). An SFD is a quantitative valuation of the system. The Dynamics of the system are evoked in the SFD, and the model construction is arranged through the elaboration of equations that pronounces how the variables are interconnected with others, and how the build-up process is determined by the change in the flows fluctuating the state of the system levels. Ogano [16] proposes that one of the chief confines of CLDs is the failure of CLDs to comprehend the stock-and-flow structure of a system. A stock is the building block of any system. Stocks are the essentials of the system that can be perceived, sensed, calculated, or measured at any given time. A system stock is an accretion of material or information that has built up over time, a reminiscence of the antiquity of fluctuating flows within the system [17]. Ogano [16] further argues that stocks change over time through the actions of a flow. Flows are filling and draining, births and deaths, procurements and sales, growth and decay, payments and withdrawals, triumphs, and disappointments. A stock, then, is the current reminiscence of the antiquity of changing flows within the system.

Sliwa [18] proposes that stocks are essential in producing the dynamics of systems, and suggests that stocks illustrate the state of the system and provide the source for their actions. The evaluation of a problem resolution is principally grounded on the stocks' values. Stocks do not have to be perceptible; stocks can be defined as representing the accretion of information, experience, invention, contagions, impetus, or professed quality of a product. Sliwa [18] further proposes that stocks are important for the following reasons:

- Stocks offer systems with inertia and memory; they accumulate historical events and can vary because of the net value of influx and depletion;
- Stocks are the source of delays;
- Stocks detach rates of flow and create an imbalance in a problem.

2.2.4 A mathematical approach to stock and flows

Sliwa [18] argues that stock-and-flow structures have an exact scientific meaning. Stocks accrue or integrate their flows with the equivalent integral equation, as denoted in Equation 1 below:

$$\text{Stock}(t) = \int (\text{Inflow} - \text{Outflow})\,(dt) + \text{Stock}\,(t\text{-}1) \quad \textbf{(1)}$$

Where (t)=final time, (dt)=time interval, (t-1) = Preceding time moment

Sliwa [18] proposes that the expression Stock (t -1) offers variables with a "recollection" assuring that the stock variable does not overlook its preceding state. Stock variables transform relative to the net flow into it; consequently, the net proportion of change of any stock is its inflow minus its outflow, defining the differential equation:

$$d(\text{Stock})/dt = (\text{Inflow - Outflow})\,(t) \quad \textbf{(2)}$$

Consequently, Sliwa [18] argues; an equivalent stock-and-flow can be effortlessly constructed from any system of integral or differential equations and in addition, a stock-and-flow map of the equivalent integral or differential equation system can be engendered.

3 RESEARCH METHODOLOGY

Kothari [19] suggests that research is a systematic investigation of appropriate information on the topic under consideration. This definition is supported by Leedy and Ormrod [20] who contend that research is a methodical process of amassing, evaluating, and understanding information to grasp a phenomenon under investigation. Pandey and Pandey [21] affirm the notion that research is an essential and compelling instrument in leading humanity to advancement. "Without methodical research, society will progress at a snail-pace" [21].

Melnikovas [22] proposes that one of the approaches to research methodology development is premised on the theoretic idea of the "research onion" advanced by Saunders et al. (2016). Melnikovas [22] further refers to Raithatha (2017) who contends that the research onion offers a comprehensive illustration of the main steps which are to be followed to articulate a robust methodology. The research onion is shown in Figure 5. It defines explicitly the layers from an all-inclusive philosophical outlook to data collection procedures and data analysis tools.

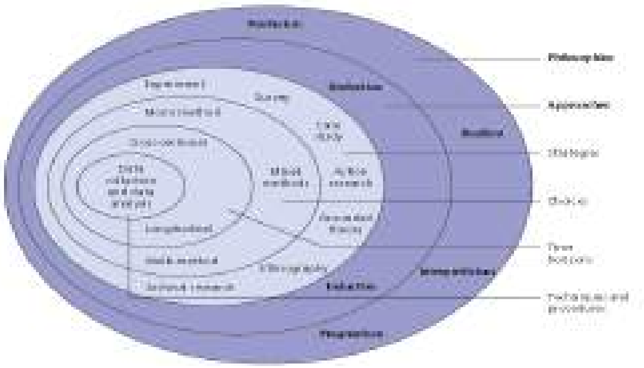

Figure 5: The research onion

This research adopted an interpretivist philosophical worldview and an inductive research approach as the research entailed theory building rather than theory testing in the first phase of the study, followed by adoption of a system dynamic research strategy underpinned by archival research which entailed a critical review of the literature to crystalise insights on dynamics that are at play in the postal digital transformation arena.The factors and concepts (theory) which emerged in the first leg of the study was subjected to a system dynamics research strategy through development of stocks and flows models provided to test the developed theory in a dynamic setting.

4 FINDINGS AND DISCUSSION

4.1 Contextualising the Integrated Index on Postal Development (2IPD) and the emergent dimensions

Mokgohloa et al [23] in their earlier research paper developed ten dimensions that emerged after saturation of data was reached through a meticulous grounded theory technique. The ten dimensions were; (i) Digital culture, (ii) Digital investments, (iii) Operational excellence, (iv) Ecosystem capability, (v) Adoption, (vi) Competitiveness, (vii) Digital capabilities, (viii) Shared vision, (ix) Customer insights, and (x) Diverging interests. The ten dimensions are vital for Designated Postal Operators (DPOs) to improve their performance on the global integrated index for postal development under the auspices of the Universal Postal Union, a United Nations agency for postal services.

The Integrated Index for Postal Development (2IPD) is defined by the UPU [24] as a relative global measure of postal development. 2IPD is a complex index that describes the performance of DPOs in 168 countries. As such, the 2IPD is an exceptional means for examining the performance of the postal sector. The 2IPD according to UPU [25] is grounded on four pillars which are (1) Relevance which appraises the vigour of demand for the full offerings of postal services compared to the finest DPOs in each category of postal activity, (2) Reliability echoes performance in terms of swiftness and certainty of delivery, across all the key segments of physical postal services, (3) Reach implies global connectedness by appraising the extensiveness and deepness of the DPOs international network. Lastly, (4) Resilience shows the degree of the diverseness of revenue streams, along with the aptness to invent and bring about a postal service which serves the broader society.

The Integrated Index on Postal Development (2IPD) is a composite stock that accumulates or depletes over time and integrates three of the seven dimensions which are digital investments, operational excellence, and digital capabilities and can be aggregated under the operations capability maturity stock. The next aggregation comprise of digital culture which incorporates shared vision dimension, competitiveness dimension resulted in financial performance stock emerging. The dimension of adoption translates to the adoption stock. Table 1 illustrates the synthesis and integration of the ten dimensions into composite stocks that emerged that were articulated earlier. Two of the dimensions are exogenous to the system and therefore are outside the boundary of the model, the two are a digital ecosystem and customer insights. Diverging interests are represented by inhibiting factors that will be articulated in the stocks and flow.

Table 1: Emergence of stocks from the seven dimensions

Dimension	Operations Capability Maturity	Digital Culture	Financial Performance
Digital culture		X	
Digital investments	X		
Operational excellence	X		
Adoption			
Competitiveness			X
Digital capabilities	X		
Shared vision		X	

The synthesis depicted in Table 1 resulted in the emergence of the four key stocks that will be utilised to develop the stock and flows. The four stocks are (1) Capability Maturity (CM), (ii) Digital Culture (DC), (iii) Competitiveness (C), and (iv) Adoption (A).

Figure 10 captures the CLD of the four stocks that were articulated in Table 1. Figure 11 characterises the hypothesis and theorises that the adoption of the UPU digital ecosystem by major clients of the postal sector will improve the financial performance of the Postal Sector. The hypothesis further theorises that leadership efforts impact on the potential adopters will improve the adoption rates and will convert potential adopters to adopters

The increase in adopters will diffuse the momentum through formal and informal communication channels which will enhance digital culture which will augment operations capability maturity which will buttress financial performance of the postal sector. Dissent or diverting interests will result in adopters falling off the system and reducing adoption rates and creating a reinforcing loop which must not be allowed to take root.

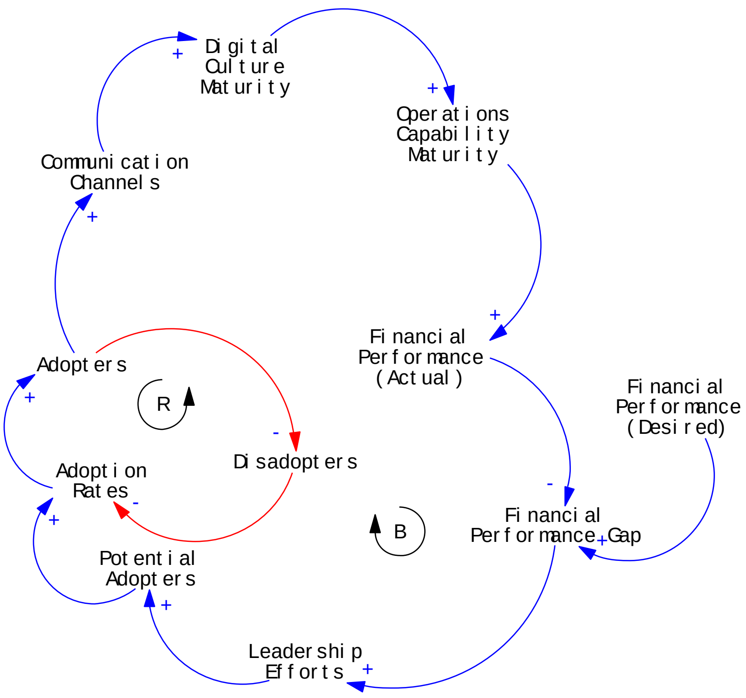

Figure 6: Postal development dynamics CLD as a hypothesis

4.2 Stocks and flows for emergent dimensions including model quantification

The four stocks that emerged and are depicted in Table 2 and Figure 11 are formulated and discussed from 4.1.2.1 to 4.1.2.4. Anylogic PLE software was used to develop the structure of the model and formulate the mathematical expressions that govern the model behaviour to mimic real-life situations. The stocks: capability maturity, digital culture, adoption, and financial performance (competitiveness) are discussed below.

The South African Post Office was selected to test and validate the model and as a result, the data used to quantify the variables were sourced from the South African Post Office and databases of the Universal Postal Union. Figure 12 is the overall model that captures the stock and flows as depicted in Figure 11. Figures 13 to 16 depict the individual stock and flow formulated with the Anylogic PLE software.

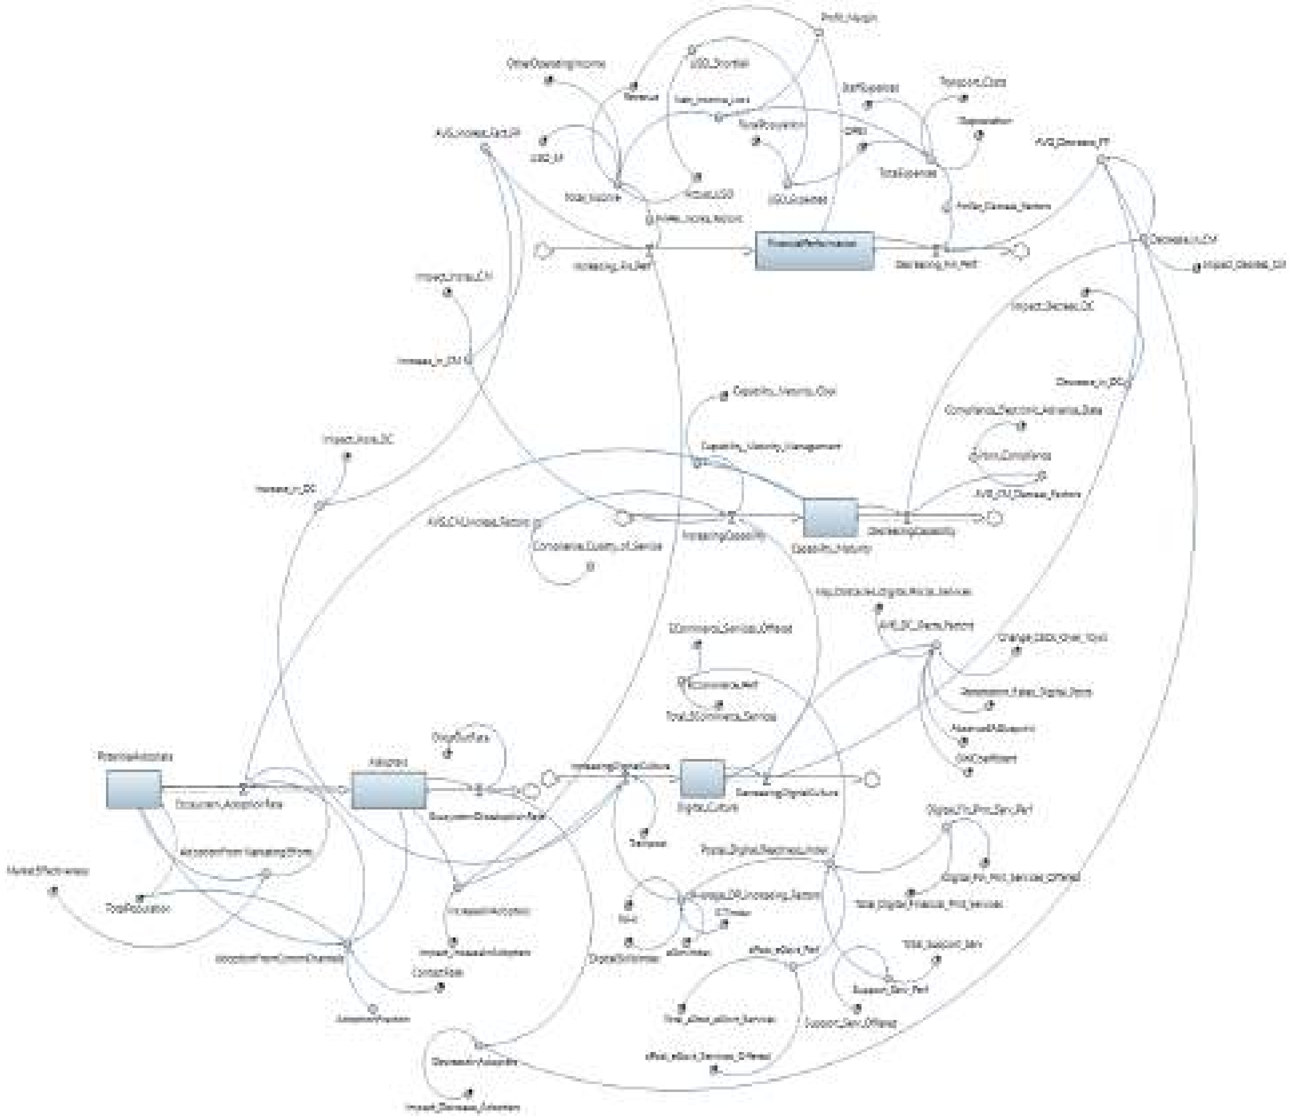

Figure 7: Postal development model with stocks and flows formulated in Anylogic PLE software

4.2.1 Operations Capability Maturity

Figure 8: Operations Capability maturity dynamics formulated in Anylogic

Figure 8 articulates the construction of the goal-seeking structure in Anylogic simulation software as well as the balancing influence loop from diverging interests (Non-compliance to Electronic Advance Data). The discussions on what each of the elements represents are articulated in the preceding chapter. The structure depicted in Figure 8 comprises a single stock which is the operations capability maturity which accumulates capability components over time, based on its flows, increasing capability, and decreasing capability. It is conceptually correct to quality assure that the model is rationally accurate which means that each flow should surge or deplete the capability maturity "stock" with "units" or components over time.

Operations Capability Maturity (CM) is defined as the difference between increasing capability maturity (ICM) and decreasing capability maturity (DCM) which can be described mathematically as in equation 3.

$$d(DC)/dt = ICM - DCM \quad \textbf{(3)}$$

Equation 3 explains that capability maturity over time is the difference between increasing capability maturity and decreasing capability maturity. The capability maturity goal is envisaged to be 0.6 and the current capability based on the 2IPD is 0.33. The gap that exists requires to be managed and as a result, capability maturity management (CMM) emerges as a concept and is defined as the difference between capability maturity goal (CMG) and Capability Maturity (CM) stock resulting in the formulation of the equation:

$$CM\ Goal - CM \quad \textbf{(4)}$$

Equation 4 explains that operations Capability Maturity Management (CMM) is a function of both the operations Capability Maturity Goal (CMG) and the current level of Operations Capability Maturity (CM).

Decomposition of equation 3 yields (i) Increasing capability maturity which is on the left side of the capability maturity stock as depicted in Figure 65 and (ii) Decreasing capability maturity which is on the right side of the capability maturity stock as depicted in Figure 65. Equation 3 represents the two flows that interact to result in the level of capability maturity. Increasing Capability Maturity (ICM) is the sum of Capability Maturity Management (CMM) and average capability management increasing factors (AvgCMIf) which comprise compliance to quality of service (CQoS) multiplied by digital culture (DC) as an increase in digital culture will affect operations capability maturity. The relationship is described mathematically in Equation 5.

$$ICM = (AvgCMIf + CMM) * DC \quad \textbf{(5)}$$

The impact of an increase in capability management (ImpiiCM) is calculated as the total increase impact factor (Tiif) minus the sum of the Impact of an increase in adoption (IiiA) and the Impact of an increase in digital culture (IiiDC). Therefore, the mathematical expression is written as:

$$ImpiiCM = Tiif - (IiiA + IiiDC) \quad \textbf{(6)}$$

Decreasing Capability Maturity (DCM) on the other hand is the difference between capability maturity and a diverging variable in the form of average capability maturity decreasing factors (AvgCMDf) which comprise the overall level of non-compliance to UPU's EAD (Electronic Advance Data) with notation (NCEAD). Therefore, decreasing capability maturity is defined as:

$$DCM = CM - AvgCMIf \quad \textbf{(7)}$$

Warren [189] argues that $X(t+1) = X(t) \mp \Delta X$ is the core theory that lies at the heart of how firms and organisations perform and argues that the rate of loss or gain of a resource (stock) over a period explains the quantity of the stock at any given time, and it does so by depleting or accumulating. It is against this theory articulated by [189] that Equation 4 and other subsequent expressions of other stocks involved in this model are conceptually and mathematically correct.

The variables articulated in equations 1, 2, 3, and 4 were computed to harmonize replication output with representative behaviour patterns and mathematical completeness. For sensible model simulation performance, the baseline values for variables are not articulated in this paper and will form part of a publication on simulation and results. This paper is confined to the development of stock and flows through the formulation of mathematical expressions.

4.2.2 Digital Culture

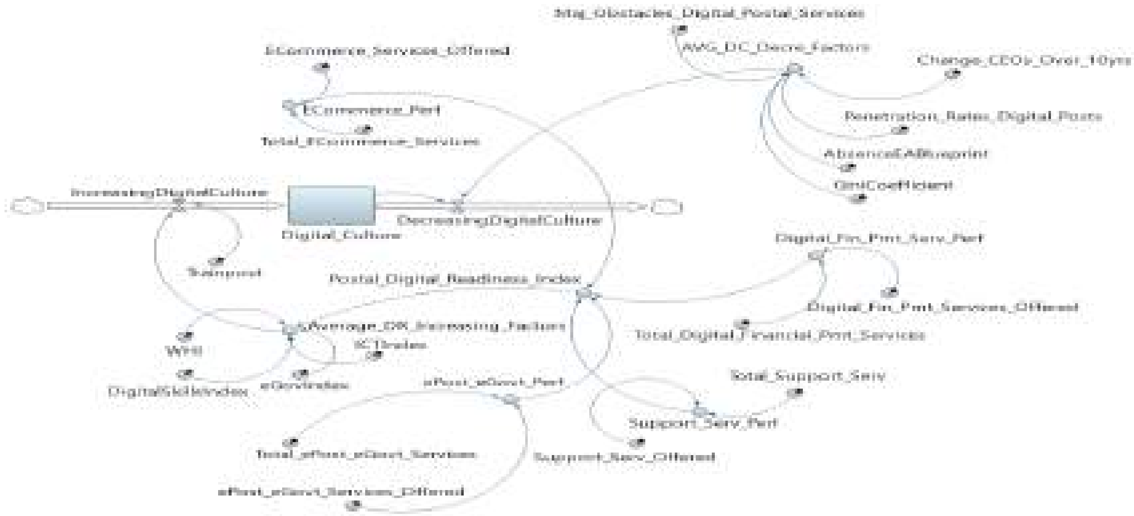

Figure 9: Digital culture dynamics formulated in Anylogic

Figure 9 depicts the construction of the s-shaped growth structure for digital culture in Anylogic as well as the unsought balancing influence from diverging interests. The structure comprises one stock which is digital culture. The digital culture stock has two flows connected to it which are an influx (Increasing digital culture) and a discharge (Decreasing digital culture). The digital culture stock accrues units of digital culture and the two flows move units of digital culture/units of time into and out of the stock.

Digital Culture (DC) is defined as the difference between increasing digital culture and decreasing digital culture which can be described mathematically as in Equation 8.

$$d(DC)/dt = IDC - DDC \quad \textbf{(8)}$$

This construction in the virtual world follows an s-shaped structure in the causal diagram for digital culture, which was derived from the reference mode behaviour pattern for digital culture. Increasing digital culture is the sum of average digital culture factors (Avg_DCIf) and the percentage of staff who attended train-post courses (SATPC) divided by two and multiplied by the increase in adopters (IiA). Average digital culture factors comprise (a) Postal readiness index (PRi) which is a composite of (i) Support Service Performance (SSP), E-commerce performance (ECSP), ePost and e-Government services performance (ePeGSP), and digital financial and payment services performance (DFPSP). (b) Global Index Factors (GIf) that drive a digital culture which is a composite of (i) Word Happiness Index (WHi), (ii) Digital Skills Index (DSi), (iii) e-Government Index (eGi), and (iv) ICT Index (ICTi). Therefore, increasing digital culture (IDC) can be expressed mathematically as:

$$IDC = ((Avg\_DCIf + SATPC)/2) * IiA \quad \textbf{(9)}$$

Where:

$$Avg\_DCIf = (SSP + ECSP + ePeGP + DFPSP + WHi + DSi + eGi + ICTi)/8 \quad \textbf{(10)}$$

Where:

- Support Services Performance (SSP) equals the support services offered (SSO) by the designated postal operator divided by the total support services (TSS) that are available in the ecosystem. Therefore, support services performance is calculated as:

$$SSP = SSO / TSS \quad \textbf{(11)}$$

- E-commerce services performance (ECSP) equals the e-commerce services offered (ECSO) by the designated postal operator divided by total e-commerce services (TECS) that are available in the ecosystem. Therefore, E-commerce services performance is calculated as:

$$ECSP = ECSO / TECS \quad \textbf{(12)}$$

- ePost and e-Government services performance (ePeGSP) equals the ePost and e-Government services offered (ePeGSO) by the designated postal operator divided by the total ePost and e-Government services (TePeGS) that are available in the ecosystem. Therefore, ePost and e-Government services performance (ePeGSP) is calculated as:

$$ePeGSP = ePeGSO / TePeGS \quad \textbf{(13)}$$

Increase in adopters (IiA) = Adopters (A) * Impact of increase in Adopters (ImpiiA) and it can be mathematically expressed as:

$$IiA = A * ImpiiA \quad \textbf{(14)}$$

Decreasing digital culture (DDC) on the other hand is the difference between digital culture and a diverging variable in the form of average digital culture decreasing factors ((AvgDCDf) which comprise the absence of EA blueprint (AEABP), penetration of digital postal services (PRDPS), Gini coefficient (GCOeff) which measures the level of inequality in society, major obstacles to digital postal services (MODPS), and percentage change in Chief Executive Officers over 10 years (CoCEO_10Yrs). O'Reilly III et al. [26] propose that the mainstream studies of organisational culture are grounded on two assumptions: (a) Leaders lead the cause of culture, and (b) Culture is interrelated to ensuing organisational outcomes. O'Reilly III et al. [26], demonstrated through the experimental results constructed on data from respondents in 32 high-technology firms, that the character of the Chief Executive Officer (CEO) influences, to a high degree, organisational culture which is thereafter connected to a comprehensive set of organisational results including an organisation's economic performance.

Therefore, decreasing capability maturity is defined as:

$$DDC = DC - AvgDCDf \quad \textbf{(15)}$$

Where:

$$AvgDCDf = (AEABP + GCOeff + PRDPS + MODPS + CoCEO\_10Yrs)/5 \quad \textbf{(16)}$$

The major obstacle to digital postal services is a composite of factors that hinder fully digital postal services in Africa. These factors are poor investments (PI), lack of digital culture (LDC), lack of expertise (LE), poor integration of merchants (PIM), poor customer adoption (PCA), inadequate training (IT), poor rate of change (PRC), difficulty in finding right external partners (DFREP), custom clearance challenges (CCC), stiff competition (SC), inadequate legal framework (ILF), and limited best practices (LBP). The equation for the major obstacle to digital postal services (MODPS) is:

$$MODPS = AVG\ (PI + LDC + LE + PIM + PCA + IT + PRC + DFREP + CCC + SC + ILF + LBP) \quad \textbf{(17)}$$

4.2.3 Adoption

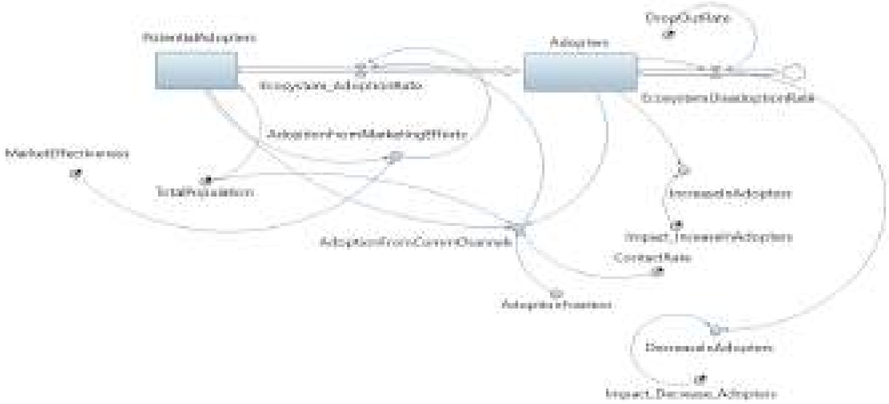

Figure 10: Adoption dynamics formulated in Anylogic

To provide context before the articulation of mathematical expressions, potential adopters are the 174 key customers of the organisation who contribute more than R10 million a month towards revenue at the South African Post Office which is used to validate the postal development system dynamics model. There are currently five key customers who have adopted and had been integrated into the UPU digital ecosystem platform. The UPU digital ecosystem platform is a complex ecosystem offering designated postal operators an opportunity to collaborate and integrate into the postal industry's industry 4.0 platform (ecosystem) which is grounded on the (i) Six industry 4.0 design principles of interoperability, virtualization, decentralization, real-time capability, service orientation, and modularity. (ii) The four Industry 4.0 dimensions of cyber-physical systems, Internet of Things (IoT), Internet of Services (IoS), and smart factories.

The adoption rate is driven by leadership efforts that are in the form of (i) Adoption from marketing efforts which represent leadership efforts to market the digital ecosystem to the 174 key customers, to convince the key customers to adopt the UPU digital ecosystem API (Application Programming Interfaces) and participate in the global postal economy. (ii) Adoption from communication channels which is driven by both formal and informal communication among adopters.

Figure 10 depicts the construction of the s-shaped growth structure for adoption in Anylogic as well as the unsought balancing influence from dis-adoption due to adopters dropping out and ceasing to use the ecosystem. The structure comprises two stocks which are (i) Potential adopters and (ii) Adopters. The digital culture stock has two flows connected to it which are an influx (Increasing digital culture) and a discharge (Decreasing digital culture). The digital culture stock accrues units of digital culture and the two flows move units of digital culture/units of time into and out of the stock.

Adoption from marketing efforts (AME) is calculated by multiplying marketing effectiveness (MI) multiplied by potential adopters (PA). Therefore, the mathematical expression can be written as:

$$AME = MI * PA \quad \textbf{(18)}$$

Adoption from communication channels (ACC) is the product of adopters' stock (A), adoption fraction (AF), and contact rate (CR) multiplied by the quotient of potential adopters' stock (PA) and total population (TP).

$$ACC = A * AF * CR * (PA)/TP \quad \textbf{(19)}$$

The ecosystem adoption rate (ESAR) is calculated by multiplying the sum of Adoption from Marketing Efforts (AME) and Adoption from Communication Channels (ACC) by Capability Maturity (CM) stock because as the capability maturity increases, it will persuade other potential adopters to adopt the UPU API's and integrate to the ecosystem to benefit from the benefits other adopters reap from UPU digital ecosystem.

The mathematical expression for ecosystem adoption rate is written as:

$$ESAR = (AME + ACC) * CM \quad \textbf{(20)}$$

The ecosystem dis-adoption rate (ESDR) represents the number of adopters (A) who discontinue the use of the ecosystem. The calculation of the dis-adoption rate is arrived at by multiplying the dropout rate (DoR) and adopter stock (A). The mathematical expression for ecosystem dis-adoption rate is written as:

$$ESDR = DoR * A \quad \textbf{(21)}$$

The effect of an increase in adopters was articulated in Equation 14 in the preceding paragraphs and further stated below:

$$IiA = A * ImpiiA \quad \textbf{(22)}$$

4.2.4 Financial Performance (Competitiveness)

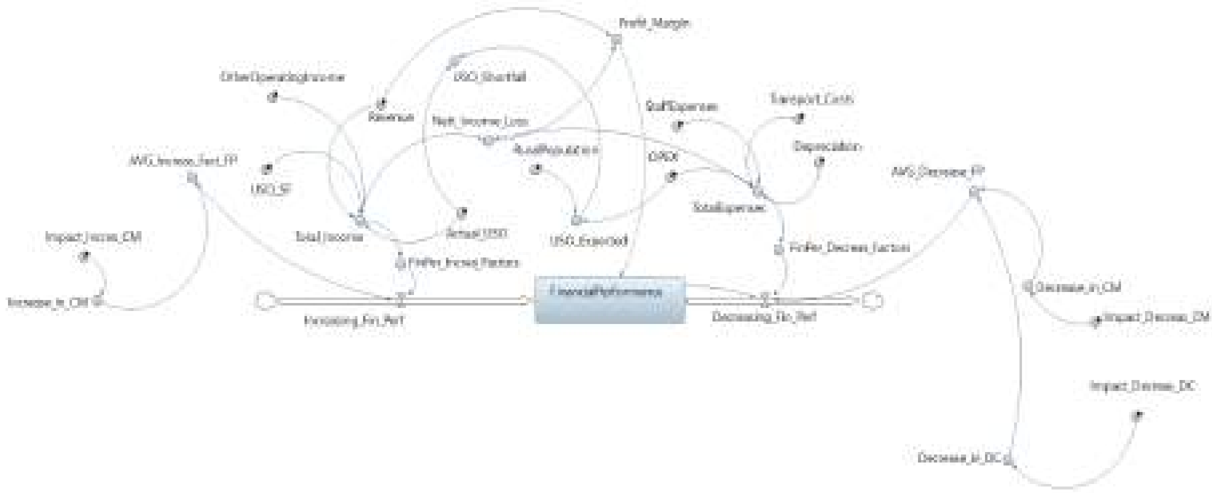

Figure 11: Financial performance (competitiveness) dynamics formulated in Anylogic

Figure 11 depicts the construction of the s-shaped growth structure for financial performance in Anylogic as well as the undesired compensating influence from discontinued use inertia. The structure comprises one stock which is digital culture. The financial performance (competitiveness) stock has two flows connected to it which are an influx (Increasing financial performance) and a discharge (Decreasing financial performance). The financial performance (competitiveness) stock accrues or drains units of financial performance, and the two flows move units of financial performance/units of time into and out of the stock.

Financial Performance (FP) is defined as the difference between Increasing Financial Performance (IFP) and Decreasing Financial Performance (DFP) which can be described mathematically as in Equation 23 below.

$$d(FP)/dt = IFP - DFP \quad \textbf{(23)}$$

Where:

Increasing Financial Performance (IFP) is the average of the sum of an increase in adopters (IiA), financial performance increase factors, and average increase factors for financial performance which can be mathematically expressed as:

$$IFP = AVG\ (FinPer\_Increa\_Factors + AVG\_Increas\_Fact\_FP + IncreaseInAdopters) \quad \textbf{(24)}$$

Where:

Average Increase Factors in Financial Performance (AIFFP) are the average increase in capability management (IiCM), increase in digital culture (IiDC), and increase in adopters (IiA). Therefore, the Financial Performance Increase Factors (FPIF) can be mathematically expressed as:

$$AIFFP = AVG\ (IiCM + IiDC + IiA) \quad \textbf{(25)}$$

An increase in digital culture (IiDC) is expressed as the product of the impact of an increase in digital culture (ImpiiDC) and Increasing Digital Culture (IDC). The mathematical expression that follows is:

$$\textbf{IiDC = ImpiiDC * IDC} \quad \textbf{(26)}$$

The Financial Performance Increase Factors (FPIF) are attributed to total income (TI) which is made up of the sum of revenue (RV), other operating income (OOI), actual universal obligation paid (AUSOPD), and universal service obligation shortfall (USOSF). The mathematical expression that follows is:

$$\mathrm{FPIF} = \mathrm{TI} = \mathrm{RV} + \mathrm{OOI} + \mathrm{AUSOPD} + \mathrm{USOSF} \qquad \textbf{(27)}$$

Decreasing Financial Performance (DFP) is attributed to (i) Financial performance decrease factors (FPDF) which are attributed to total expenses (TE) which are made up of the sum of transport costs (TC), staff expenses (SE), operational expenses (OPEX), and depreciation (DEP). (ii) Average decrease in financial performance (ADFP) which is attributed to the average decrease in capability maturity (DiCM), decrease in digital culture (DiDC) and decrease in adopters (DiA). (iii) Financial performance stock

The mathematical expression that follows is:

$$\mathrm{DFP} = \mathrm{FP} - (\mathrm{ADFP} - \mathrm{FPDF}) \qquad \textbf{(28)}$$

$$\mathrm{FPDF} = \mathrm{TE} = \mathrm{TC} + \mathrm{SE} + \mathrm{OPEX} + \mathrm{DEP} \qquad \textbf{(29)}$$

5 CONCLUSIONS AND RECOMMENDATIONS

This paper articulates the model conceptualisation which is grounded on the research undertaken by Mokgohloa et al. [23] from where ten dimensions (variables) emerged. The dimensions (variables) were further developed into causal loop diagrams or rather “influence diagrams” which unambiguously demonstrate the dynamic feedback relationship between variables within each sub-system in the study by Mokgohloa et al [27]. In that research, both exogenous variables (outside the boundary) and endogenous variables (within the boundary) were identified. The endogenous variables excluding the digital ecosystem, which is exogenous but the subject of the study, were synthesized into causal loop diagrams or “influence” diagrams to describe their interaction in a dynamic setting. The influence diagrams were supplemented by a detailed explanation of the interconnectedness and the loop dynamics for each of the variables presented as causal loop diagrams or CLDs.

This paper further articulates the stocks and flows that emerged from the preceding research by Mokgohloa et al. [27] which dealt with CLDs. The ten dimensions that were discussed in the preceding chapter are further refined and streamlined and described in Table 1. The resultant dimensions are consolidated, and a new causal loop diagram emerges which comprises capability maturity, adoption, digital culture, and financial performance (competitiveness). The emergent CLD has depicted in Figure 6 and grounds the hypothesis in the context of the realities and material conditions that are at play in the postal sector.

The restated hypothesis was presented which theorises that the adoption of the UPU (Universal Postal Union) APIs (Application Programming Interfaces) by key customers of the postal sector will reinforce a robust digital culture. This culture will thereafter strengthen the operations capability maturity of the postal sector and the three stocks will reinforce financial performance (competitiveness) of the postal sector which will ensure the sustainability of the postal sector.

This paper further quantified the variables and developed the mathematical expressions for respective stocks and flows. As a recommendation for future research, the developed stocks and flows should be subjected to model verification and validation tests, and finally policy analysis and design. Sterman [4] proposes that policy design incorporates the development of novel stratagems, structures, and verdict guidelines; and the sturdiness of policies and their responsiveness to unpredictability in the model parameters and structure must be evaluated.

This comprises their performance under an assortment of diverse scenarios, as well as the interplay of diverse policies.

ABSTRACT

South Africa has a history of poor performance on large complex construction and development projects, typically Systems of Systems (SoS) integration projects. The most recent failures include the highly publicised Medupi and Kusile projects. A significant component of their failings can be attributed to poor systems engineering and systems engineering management capabilities during the project lifecycle. Most large organisations undertaking complex systems engineering projects in the construction and development sector do not possess internal functional structures that support developing a systems engineering management capability. Literature indicates that the role of complex interface management and project integration is the responsibility of systems engineering management. This research explores the general causes of failures within complex systems engineering projects in the construction and development industry. Outcomes will be used to develop and propose a framework to support the development and performance of systems engineers and systems engineering managers in such environments.

Keywords: systems engineering management, systems thinking, complex projects, development

1 INTRODUCTION

The Systems Engineering Manager (SEM), which is the final line of progression within the System Engineering (SE) field, directs the design, development, synthesis, and creation of a system based on customer needs, acting as a “chief designer” of the system rather than just being the system analyst [1]. Although research and development in the field of SE have improved our abilities in the interpretation, design, development, implementation, and management of single systems over the past 50 years, we still face significant challenges with the relatively new phenomenon of Systems of Systems Engineering (SoSE), i.e., the integration of multiple complex systems [2].

Carlock and Fenton [3] highlighted that SE handbooks frequently describe the development of individual stand-alone systems, i.e., systems that are identical and deployed similarly at any site location. Developing Systems of Systems (SoS), particularly systems that involve integration with several existing or legacy systems, is a far more significant challenge than developing stand-alone systems. Each system has unique capabilities, constraints, budgets, schedules, and interface requirements that must be considered during development and integrated to work effectively as a synergistic whole. Examples include the integration between different generations of hardware and software or lifecycle stages of systems in the case of brownfield expansions or upgrades. The SoS is generally a heterogeneous system, implying that each system or sub-system of the SoS is generally custom-built or developed to suit specific site conditions of the regions in which they are deployed [3].

Complexity is further exacerbated by the fact that the integrated SoS is a consolidation of independent systems developed by numerous organisations. Although substantial research has been undertaken to address aspects such as risk, uncertainty, schedule urgency, and various other issues in the megaproject environment, the complexity issue has received limited attention. This is surprising given the extreme demand for organisational capabilities required to manage complexity in the megaproject environment. In most instances, poor megaproject performance was attributed to a lack of prior organisational experience and capabilities [4]. This research's System of Interest (SoI) includes complex engineered systems (large-scale plants) as an SoS, such as oil refineries, petrochemical, electric power generation, and mineral processing plants [5]. Procurement of such facilities requires SoSE Management’s capability to manage the integration of independent systems to ensure a successful outcome [6].

Most organisations manage risks associated with acquiring such facilities by transferring the risk to an Engineering Consultant who acts for and on behalf of the owner. Irrespective of how the project is contracted, SEMs with robust Systems Thinking (ST) and SE capabilities are essential to facilitate the system interface integration management necessary to achieve the desired outcomes.

SEM in this environment requires broad-based inter-disciplinary engineering skills at a level considered to be a specialist amongst generalists, capable of managing interfaces and complex integration between teams of domain specialists [7]. Acquiring such knowledge will require meaningful cross-disciplinary exposure and a commitment to remain in the field for a long time. System Engineering Managers (SEMs) must develop such capabilities since the success of a project, from an SEM perspective, is not measured based on quality, cost, and schedule in the short term but also on plant performance over time, i.e., year 1, year 2,…. year 7 or decades [8]. Failure to develop these skills will inevitably result in cost, schedule overruns, and performance implications.

In many instances, performance issues do not show themselves immediately but generally manifest in operational cost escalation over time. This has been a constant challenge for South African organisations, with many megaproject failures impacting the economy in recent years. Prime examples of such failures are the Medupi and Kusile plants at Eskom

[9]. Some of the general causes of poor performance on these projects include the late approval of contracts and design drawings, design errors, poor scope definition resulting in late scope changes, and poor technical management capabilities [10].

A major component of the project's failings can be attributed to poor SEM capabilities during the project lifecycle. A general engineering manager from a functional background or operations support role may not possess the appropriate experience or skillset to perform the role as a technical track lead of large complex SoSE projects. That is the function of an SEM who is considered an expert in managing complex interfaces and integration. Where do such individuals come from, given that they are so challenging to develop? Are we guilty of executing sizeable complex construction and development projects with gaps or inappropriate skills within the project leadership structure/hierarchy? Tertiary institutes and large industries in South Africa need to invest in developing and applying a suitable framework to improve SEM capabilities.

2 METHOD

The nature of the research problem, questions and propositions are aligned with a relativist ontology and a constructionist epistemology, i.e., many truths apply to this topic or questions [11]. However, not all will be relevant to the context of this study. For instance, no single reality or issue impacts the development of SE and SEMs in South Africa. Examples are socio-economic conditions within the country resulting in limited availability of resources to fund projects to support development and encourage staff retention and corruption, which also constrains resource availability. Such issues are not directly within the control of tertiary institutions or industries and have little relevance to a framework for developing system engineers and SEMs. Furthermore, the viewpoints of the individuals regarding barriers to performance will vary based on their perspectives and experiences.

The primary research design is aligned with a qualitative research paradigm to develop theories and foundations to validate or reject the research propositions proposed based on secondary research [12]. Relevant propositions will test the validity of competencies in the proposed framework for developing Systems Engineers and SEMs performing roles in large, complex SoSE project environments. The literature survey combined a structured narrative method and a critical review. The primary focus of the research was highlighting gaps in the development and capabilities of SEM in South Africa. Peer-reviewed journal articles focusing on complex, large-scale construction projects were preferred. The number of citations was also used to measure the quality of the source. Old, outdated material was generally discarded.

The literature review used the draft research questions that informed phrases and keyword searches as sub-section headings. Search questions were designed to explore literature from a broad range of fields, such as SE, ST, Engineering Management, Project Management and Construction Management, to identify relationships with poor performance in SEM. An overview of all research applicable to the search questions and a critical review and analysis is provided. The entire process is depicted in the mind map in Figure 1 below.

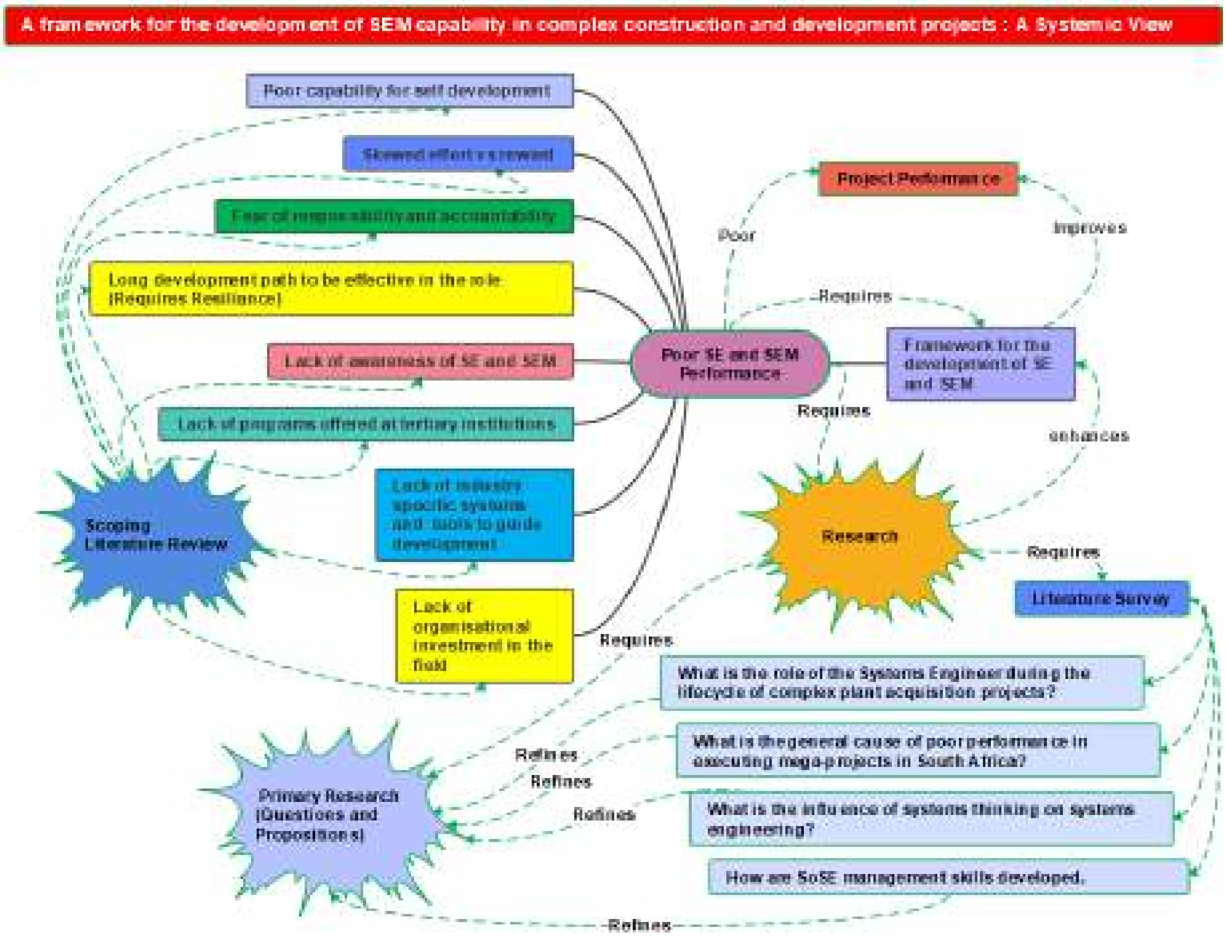

Figure 1: Mind Mapp of Research Method

3 LITERATURE REVIEW

3.1 What is the Influence of Systems Thinking on Systems Engineering?

According to Greene and Papalambros [13], educators and practitioners have acknowledged the value of ST and its positive influence on successfully designing large-scale complex systems. The authors believe it plays a vital role in mitigating several problems resulting from the increasing complexity of large-scale engineered systems [13]. Castelle and Jaradat [14] reinforced this view, citing that the ST paradigm, which supports a holistic approach to evaluating solutions to complex problems, will prevent teams from solving the wrong problems precisely. There is no one-shoe-size-fits-all approach to ST. This implies that a reductionist approach to solving complex engineering problems with a narrow scope field is only beneficial in specific circumstances. Holistic Systems Thinkers must resolve complex multidisciplinary problems requiring a collaborative effort, i.e., ST has a complementary effect on resolving complex SE problems [8, 14].

Frank and Kordova [15] argued that ST is a primary high-order thinking capability that allows individuals to view systems, enhancing success in performing SE tasks. The authors claimed that Systems Engineers must possess skills and experience to apply a “systems view” or display a high system thinking capability to be successful in SE roles. They also raised an interesting view regarding the origins of the ability, i.e., is it natural or developed [15, 16].

Monnat and Gannon [17] used examples of major project failures to highlight how the application of ST in early SE project development processes could have prevented the adverse outcomes. Applying the outward-centric ST in SE enhances the ability to identify external factors such as environmental factors (temperature, wind, rain, sources of resonance), social factors, aesthetics, maintenance, and disposal to ensure that the developed system is technically and commercially successful. Experts the world over expressed the importance and positive influence ST attributes, such as understanding complexity, big-picture thinking (holism), component interfaces and interrelationships, framing a problem (problem structuring), and experiential learning can have on solving problems within complex SE plant acquisition projects [18].

Monnat and Gannon [17] argued that although there is an awareness of the synergistic relationship between ST principals and SE and that applying ST to SE improves engineering outcomes, limited literature is available to guide how to apply ST to SE. Greene and Papalambros [13] indicated that ST in engineering had been understudied due to a limited group of authors contributing to publications in engineering.

Gaps - Several scholars have raised gaps regarding the lack of research in ST associated with SE or frameworks/guidance on how to develop ST within SE. One of the significant challenges is that although scholars universally agree that ST is a critical tool and enabler of performance in the SE field, the application and ST attributes required by Systems Engineers and SEMs are based on the context or area in which it is applied. Little to no literature is associated with developing or applying ST to SE components of complex construction-type projects. Given that some scholars question whether ST can be developed combined with the absence of a framework applicable to this context, it is difficult to screen individuals with the potential to perform effectively in SE, which requires ST capability. Almost no research is available regarding ST and its application and influence on SE over the life cycle of complex plant acquisition projects or SoSE projects.

3.2 What is the Role of the Systems Engineer during the Lifecycle of Complex Plant Acquisition Projects?

According to Chan [19], the Systems Engineer is the individual within the project team who a) evaluates the solution to problems considering a broad range of relevant scenarios, b) delivers a well-balanced technical solution, and c) manages the integration between technical domain resources and specialists within design, safety, reliability, and constructability to develop the solution to complex SE projects.

Zhu and Mostafavi [20] highlighted the dynamic nature of large complex construction projects comprising a variety of sub-systems, such as design, procurement, contract management and administration, safety management and risk management. Each sub-system performs a specific function; for instance, the design team translates Users' requirements into design drawings and specifications for construction. These sub-systems interface and interact with every other sub-system within the system [20]. Changes in any sub-system generally directly affect others, causing the project to deviate with time. A typical example is a design change that affects the design sub-system but also affects construction, procurement, and risk management sub-systems. Changes in procedures may impact construction. Procurement may need to supply alternative materials and equipment. The project risk register may need to be updated once the design error has been eliminated. However, new risks may materialise, such as schedule impact due to changes in material, equipment, or fabrication requirements. The final configuration of the project may differ significantly from its original concept, highlighting the dynamic nature of complex construction projects [20].

Frank and Kasser [21] highlighted three competencies associated with knowledge and experience critical to a Systems Engineer's success. These include a) an expert level of experience in an engineering discipline, for instance, process, electrical or industrial engineering; b) multidisciplinary and interdisciplinary technical knowledge of other engineering domains relevant to the work environment; c) sufficient work experience as a domain engineer and Systems Engineer on several complex SE projects. SE experience in the industry is role-specific; for instance, the Systems Engineer working in marketing requires different skills than a counterpart working as an integration lead in complex project development roles. The Systems Engineer's role depends on his level and experience within the project structure. For instance, an apprentice can execute tasks under the supervision of experienced Systems Engineers. The highest level of performance and rare skill is the ability to analyse a situation, define the problem, develop a solution, and plan the implementation of the solution [21]. Such individuals will typically perform lead roles within the project structure.

Multidisciplinary knowledge does not imply a broad range of awareness or knowing a little about a lot. Although the level of multidisciplinary knowledge required by Systems Engineers need not be at a specialist level, a significantly high level of understanding is required to effectively manage interfaces and integration between specialists from supporting domains [22].

Gaps - Who is the Systems Engineer in large complex plant or SoSE projects in South Africa? Such facilities are generally dominated by mechanical, civil, and structural hardware. Does an electrical or electronic engineering background provide the appropriate experience for performing the SE role in such projects, given that most of the costs flow during the execution phase? A typical example of such a facility is a Petrochemical Plant or Power Plant. The technical team on such projects will generally consist of engineering representation from almost all engineering domains, for instance, civil and structural, process, instruments, and controls, electrical, mechanical, metallurgical and fabrication specialists. Systems in such facilities will typically consist of utility supply systems, feedstock and raw materials handling systems, energy supply systems, control systems, production systems and inventory management systems. Although control rooms, electrical sub-stations and additional electrical and control artefacts can form a significant portion of the overall scope in a new plant when required, the electrical and control scope in a process plant-type facility is generally dwarfed by mechanical, civil, and structural artefacts. An electrical or control engineer's background may not provide the broad exposure required to effectively perform the systems integration role in projects by applying the whole lifecycle approach accustomed to SE.

Zhu and Mostafavi [20] highlighted an example of a late design change that affects the design sub-system but also affects construction, procurement, and risk management sub-systems. Additional examples include delayed equipment orders and technology or material substitution decisions that follow because of schedule risk mitigation. Such changes generally impact an array of interfaces, including metallurgy, the design team (modelling, mechanical and piping, process, controls, civil and structural), fabrication, procurement, construction management, risk management and planning. Identifying the impact of change early is essential for effective change management, a critical skill in a complex, large project environment. Do control and electrical engineers have the necessary experience or exposure to identify and manage all interfaces impacted by such decisions? Computer engineers do not apply to this context, nor does an industrial engineer. The main components of the Electrical, Electronic and Computer Engineering programs offered at the University of Pretoria are indicated in Table 1 to reinforce this view.

The experience of process engineers in applying the whole life cycle approach to design in the context of this study is also questionable. On the other hand, the mechanical engineering degree is offered from a generalist perspective covering electrical, electronics, fluids, thermodynamics, heat and mass transfer, metallurgy, vibrations (dynamics), mechatronics, hydraulics, the strength of materials as well as the design of physical artefacts as core elements [23]. Given that the mechanical and piping role on complex plant development type projects overlaps the broadest range of domains, are high-potential mechanical engineers in a more favourable position to develop into and perform the role of the SE and SEM effectively?

Table 1: Core elements of Electrical, Electronic and Computer Engineering at the University of Pretoria (University of Pretoria, 2023)

ELECTRICAL ENGINEERING	ELECTRONIC ENGINEERING	COMPUTER ENGINEERING
Linear signals and systems	Circuit theory	Circuit theory
Digital systems and microprocessors	Linear signals and systems	Linear signals and systems
Power system components and analysis	Microprocessors	Microprocessors
Energy systems and optimisation	Communication systems	Computer networks
High voltage protection	Electromagnetics	Computer architecture and systems
Electrical machines	DSP programming	Software engineering
Power electronics and electrical drives	Advanced electronics	Intelligent systems
Control systems and automation	Control systems	Network security

Furthermore, as highlighted by scholars, NASA and the Systems Engineering Handbook (INCOSE), the project leadership structures refer to Systems Engineers and SEMs as technical track leads. There is no reference to the general Engineering Manager or Engineering Management role in SE project structures based on international reference material. The NASA Framework in Figure 2 illustrates this view. Since complex plant construction projects, such as a petrochemical plant, are defined as complex SoSE projects, it stands to reason that Systems Engineers and SEMs should lead the technical track leadership structures. Industries need to start applying the correct terminology in the project delivery environment to avoid contaminating such structures with inadequate experience in project leadership roles.

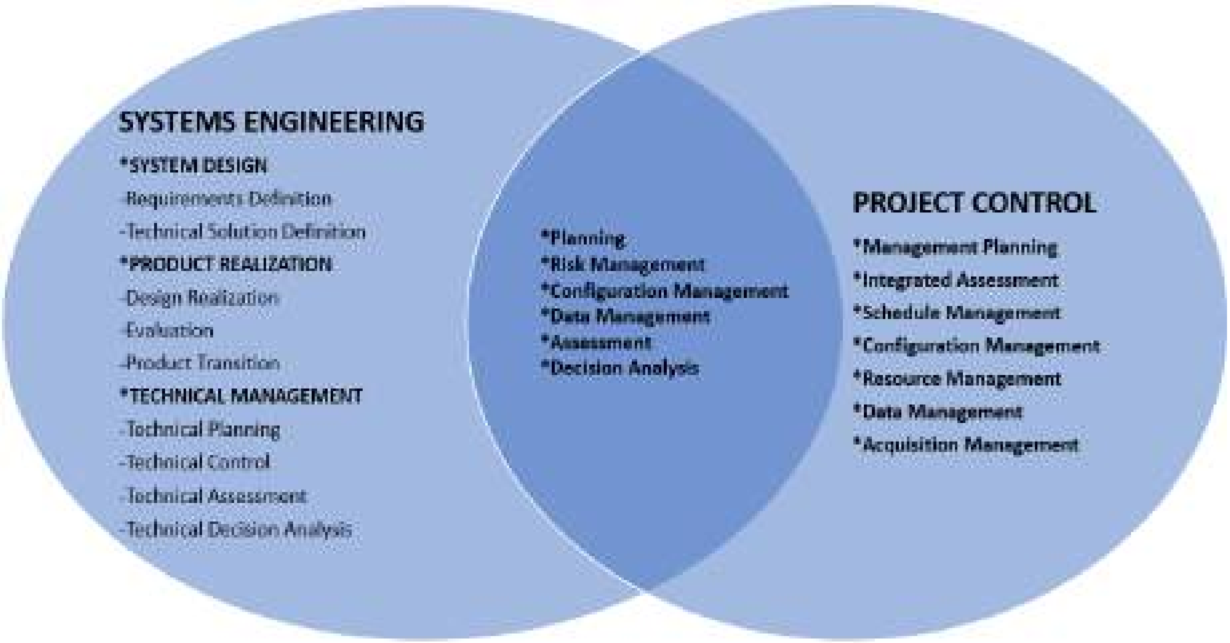

Figure 2: Interface between Systems Engineering and Project Management adapted from NASA [24]

3.3 How are Systems Engineering and Systems Engineering Management Traits and Skills Developed to Improve Systems of Systems Engineering Project Success?

Given the criticality of the SE role, the screening process for the shortlisting of candidates for SE roles should be stringent and reliable to ensure that only applicants who are likely to succeed are accepted. One of the critical traits to enhance success in SE positions is a keen interest and strong will to be a Systems Engineer [25]. Placing the wrong candidates in Systems Engineering positions can be an expensive error, given the cost of development and errors on Systems Engineering projects [21].

Gaps – Frameworks developed by scholars, communities and organisations are currently developed from a general or specific industry perspective. For instance, the NASA framework may contain overlapping content but will certainly not cover all elements or competencies applicable to complex SoS plant-type projects. None of the literature or frameworks provides guidelines on how these skills can be developed or applied as part of a competency development program. An example is the INCOSE framework, which prescribes skills and competencies applicable to SE [26]. Although INCOSE does well to isolate the core competencies applicable to SE, it does not provide a criticality ranking for these skills, which might benefit large industries undertaking large-scale acquisition projects. A criticality ranking will aid in guiding the development of the SE from a risk perspective since a SE possessing 50% of the skills that are less critical to the application context may still represent a high risk to the project.

Also, since SE and SEM competencies are context-dependent, and extant literature suggests that a Systems Engineer and SEM should be an expert in a field and have an overarching knowledge of all other domain engineering fields applicable to his application context, one would feel naturally inclined to question INCOSE's prescribed list of core skills. Why are technical skills not included in the list of core skills? The latest INCOSE framework excludes domain-specific skills since this is industry-specific but introduces other challenges. Since domain-specific skills are critical to Systems Engineers performing roles in complex plant integration projects, industries lacking screening tools or frameworks are often guilty of applying poor selection processes for systems engineering roles [26].

3.4 What is the General Cause of Poor Performance in Executing Megaprojects in South Africa?

According to Tshidavhu and Khatleli [10], surveys with quantity surveyors, engineers and project managers who participated in Megaprojects in South Africa, including Medupi and Kusile, revealed that poor planning and slow decision-making, inaccurate estimation, increased material costs and late contract awards were the primary causes of cost and schedule overruns in Megaprojects. The authors also underlined typical factors resulting in the poor performance of construction projects of varying scales, including design changes, late approval of design drawings, design errors, late scope change (on-site) and poor management capabilities during design and construction [10]. Planning, decision management, procurement and contract management, risk management, concurrent engineering, design integration, and interface management are all roles and responsibilities of systems engineers and SEMs [27]. Failings in these areas, as was the case in both the Medupi and Kusile projects, are indications of poor SE and SEM performance on these projects.

Ika [28] states that applying a one-size-fits-all approach to the execution of projects in Africa is an underlying cause of poor performance. Although several issues were highlighted in various categories associated with the execution of the Medupi project, items of relevance captured under management and organisational problems were poor consideration of water availability (water scarcity), health implications for nearby communities and challenges with local services and capabilities within the project design phase [28]. This indicates a failure to apply the ST paradigm, which supports a holistic approach to evaluating solutions to complex problems during the project's design phase [14].

According to Rafey and Sovacool [29], Medupi, which was Eskom's biggest single investment in 60 years, intended to supply 10% of SA's electricity demand, generates more emissions than 63 of the lowest-emitting countries combined [29]. Kusile and Medupi will be operated at reduced load factors from 2026 [9]. Once again, this indicates failures to apply holistic thinking traits conducive to ST and the life cycle design approach conducive to SE. Reduction in the load factor on account of environmental emission constraints indicates a failure to account for environmental compliance regulations (environmental engineering) during the design phase. This also highlights failings in cross-functional interface management, which is a responsibility of the SEM. Nkambule and Blignaut [30] applied a system dynamics approach to measure and quantify coal-fuel cycle challenges and externality costs over the lifecycle of the Kusile Plant. The model indicated that consideration for external factors over the facility's life cycle resulted in price escalation per unit of electricity produced between 200-400% [30]. This again highlights the benefit of applying the life cycle approach to engineering conducive to SE and the ST paradigm (holistic thinking). ST, SE, and SEM capabilities appear to be gaps within large, complex SoSE project structures.

4 CONCEPTUAL FRAMEWORK

4.1 Introduction

Gaps in the development of ST, SE, and SEM highlighted the importance of awareness of SE and related fields, its link to performance, and a need for an industry-specific framework to guide the development of SEM capabilities within the industry context. As mentioned, competency frameworks exist in a generic form to be customised to their application context. A popular framework is the INCOSE Framework, developed for general industrial applications [26]. Naturally, domain engineering skills (technical competencies) applicable to different industries are excluded from this framework. This intentionally allows industries to include skills directly applicable to their sector. The framework proposed in Table 2 is a customisation of the generic INCOSE framework used as a base to develop an industry-specific framework for system engineering management.

Although the framework was developed for SE, it is also relevant to the field of SEM, which is the most advanced role in the SE career ladder. The approach is to identify critical competencies that can be considered a risk, i.e., competencies that cannot be generically developed. These critical competencies should be used to screen applicants who are most likely to be successful in the SE field applicable to the industry context. This ensures a strong pool of candidates with the capabilities to develop the characteristics required to progress into SEM roles successfully. The 2nd area of interest is the critical competencies required to be successful as an SEM in this sector.

To develop a suitable framework, the research questions were designed to identify the competencies critical to performing SE and SEM roles in the environment relevant to the context of this research. The research questions are listed below:

- What is the impact of SEM on success or performance in large complex SoSE projects?
- Who performs the role of the SEM throughout the lifecycle of large complex SoSE projects in South Africa?
- What are the core competencies required to be effective as an SEM in large complex SoSE infrastructure projects?
- How should the framework be applied to improve SEM performance in large complex SoSE infrastructure projects?

Table 2: Proposed System Engineering and System Engineering Management Competencies

Core Competencies	Professional Competencies	Management Competencies	Technical Competencies	Integrating Competencies	Domain Engineering Competencies
Systems Thinking	Ethics and Professionalism	Planning	Requirements Definition	Project Management	Mechanical Engineering
Lifecycles	Technical Leadership	Monitoring and Control	System Architecting	Finance	Civil Engineering
Capacity Engineering	Negotiation	Decision Management	Design for:	Logistics	Structural Engineering
General Engineering	Team Dynamics	Concurrent Engineering	Integration	Quality	Control Engineering
Critical Thinking	Communication	Business and Enterprise Integration	Interfaces		Electrical Engineering
Systems Modelling and Analysis	Emotional Intelligence	Acquisition and Supply	Verification		Process Engineering
	Coaching and Mentoring	Information Management	Validation		Environmental Engineering
	Facilitation	Configuration Management	Transition		Geotechnical Engineering
		Risk and Opportunity Management	Operation and Support		Metallurgy and Welding

Open-ended search questions based on research questions were designed to allow a rich data pool to be gathered through secondary research. The secondary data was used as a basis to develop the preliminary framework for the industry context, illustrated in Table 2. Research propositions derived from the literature review and aligned with the content of the proposed framework will be tested through primary research. The propositions are outlined in the following sections.

4.2 Effective Screening for Systems Engineering Roles

SE roles in complex SoS construction projects are among the most demanding in the SE field. Progression to the roles of senior Systems Engineer and SEM requires high intelligence, resilience, and strength of character to shoulder the overall responsibility and accountability that comes with such positions. Not every individual can be effective in this role. For instance, domain engineers from projects and maintenance may not be interchangeable. SE errors in the construction industry represent a significant short- and long-term cost risk due to poor plant performance or being beaten to the market by competitors because of schedule delays. This leads to research proposition P1:

P1: Stringent competency screening tools for Systems Engineering roles will assist in improving Systems Engineering and System Engineering Management performance.

4.3 Core Skills of Systems Engineers for Complex Plant Integration Projects

Some skills are more important than others in Systems Engineering roles, considering that very few, if any, individuals will be allowed to acquire all the competencies before performing the role or within his/her career. An example would be interpersonal skills or people skills. An individual scoring high on people skills and low on technical skills will not necessarily be capable of developing the technical skills. This leads to the second proposition:

P2: Some skills are more important than others to enable effective performance in Systems Engineering roles.

4.4 The Long Road to Success

To gain skills to perform at higher levels within the project hierarchy requires patience and a desire to remain in the field for a long time. This is because of the broad range of competencies required to be effective in these roles. It also requires exposure to the right environments to develop the range of knowledge required to be effective at interface management and integration. Although a career in SE may not be ideal for those pursuing instant gratification, organisations need to be wary of talent and implement effective reward strategies to retain System Engineers. Systems Engineers are specialists with context-specific skills requiring a long turnaround time to replace lost capability. In some instances, lost capability cannot be replaced. This leads to the following propositions:

P3: Context specific experience is directly linked to effective performance in SEM roles.

P4: Broad-based technical domain knowledge is directly linked to effective performance in SEM roles.

P5: Individual capability and prior experience impact knowledge adoption rate and performance in SE/SEM roles.

4.5 Framework

The research propositions and framework proposed in this chapter will be tested through primary research and used to develop a suitable framework for the industry context. The conceptual framework of this process is depicted in Figure 3.1 that follows:

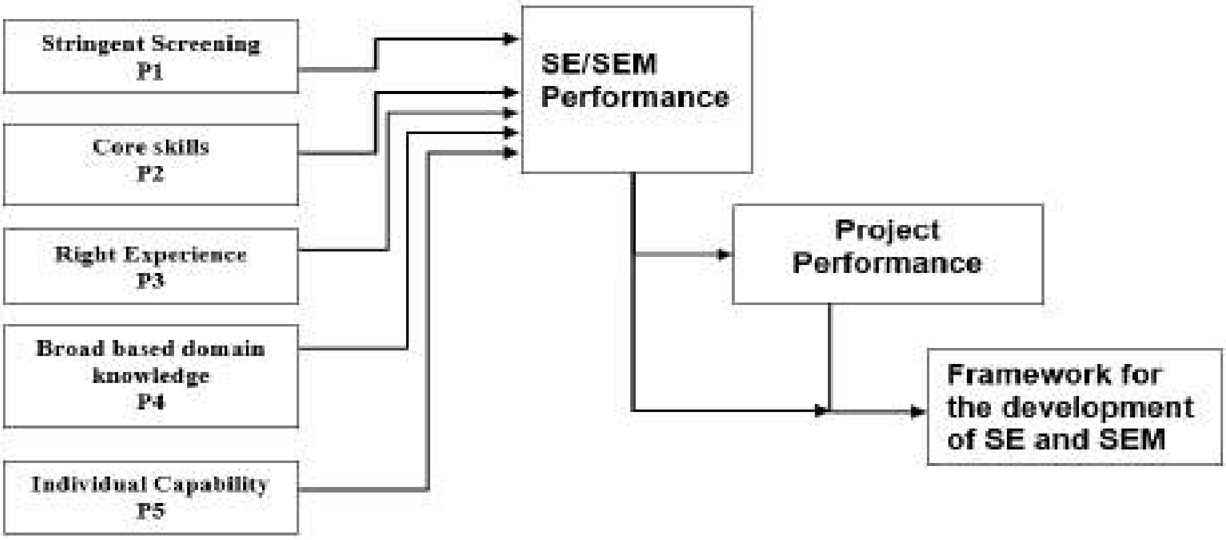

Figure 3: Conceptual Framework for Research

The framework illustrates that the proposed research propositions that positively impact SE/SEM and, ultimately, project performance will be used to test the relevance of the proposed framework. The relevance of the research propositions will be validated based on the data analysis outcomes from primary research, i.e., the primary research is used to validate the outcomes of secondary research. The themes and line of questions used to develop interview questionnaires will be designed to test the relevance of the propositions.

The research propositions proposed are not exhaustive, i.e., research propositions will be modified based on new findings that emerge from inductive research methods. Findings will also be used to update the research questions, where applicable. The final SE/SE management development framework proposed in this research assignment is an outcome of an iterative process.

The Causal Loop Diagram in Figure 4 summarises the literature review to illustrate how an industry-specific framework for developing SE and SEM will benefit the project and organisational performance. The framework will guide the development of competencies necessary to improve SEM, which improves inter-disciplinary, multidisciplinary, and cross-functional interface integration in projects. An improvement in SEM improves the quality of requirements engineering, ensuring that aspects such as geographic and environmental requirements, Legislation, Codes and Standards, Owners' Specifications, Operations, Maintenance requirements, and gaps or project-specific requirements are accurately defined. A key element to improve the chances of success in complex projects is to manage the domino effect of change, from the onset. This starts with a quality framing agreement and design basis, where requirements are formally captured and agreed with the client. This results in higher quality scopes, reducing scope change. Concurrently, this improves project management support quality, risk management and planning, ensuring effective contracting strategies and information management.

Effective contract management and information transfer during design development improve the quality of concurrent engineering, i.e., the interfaces and information flow between teams responsible for developing independently procured systems and the integrated design package (SoS). Typical systems include mechanical, electrical, and electronic equipment and appurtenances. Information delays or late changes within these systems, such as technology changes, have a knock-on effect on the integrated systems, impacting equipment layout, support requirements, system configurations and interface loads.

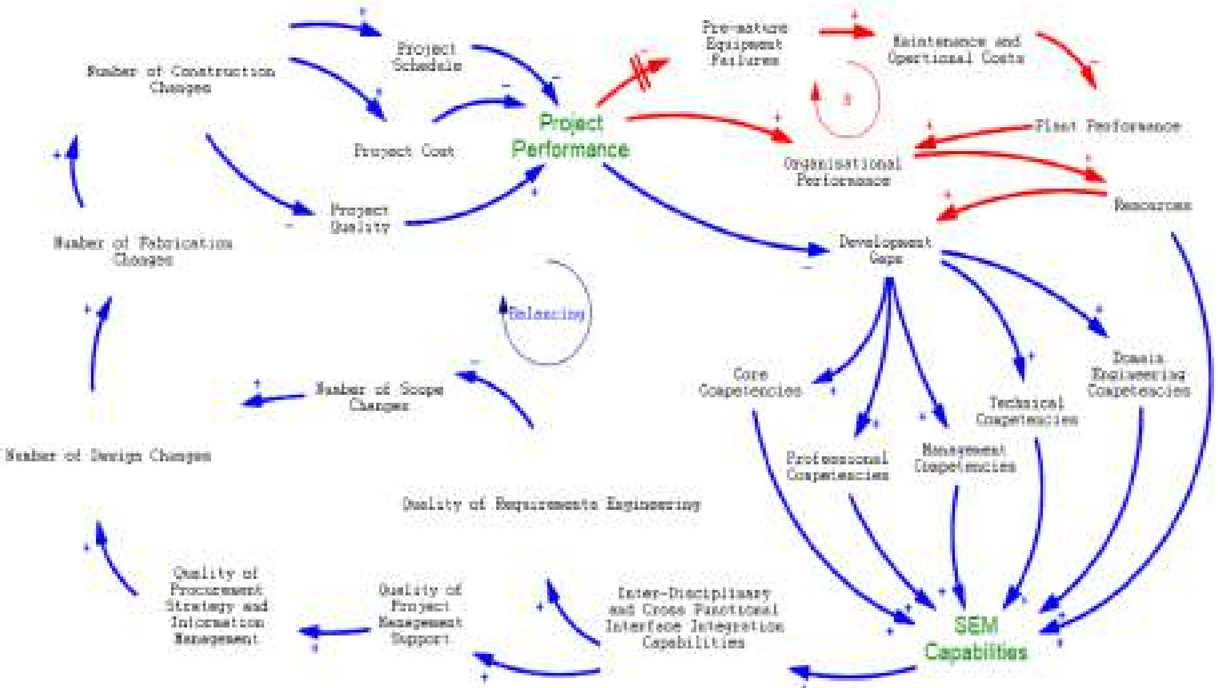

Figure 4: Causal Loop Diagram illustrating the benefits of applying a Development Framework for Systems Engineering Management within the Industry

A change in technology requiring a configuration change will often have a knock-on effect on other technologies due to changes in hydraulic and pneumatic requirements that impact the sizing of pumps, compressors, and blowers within the system. This may impact energy demand due to changes in motor sizing. This domino effect impacts various elements of discipline engineering (inter-disciplinary), other disciplines (multidisciplinary) and functions such as cost control, planning and contract management, to name a few. Ultimately, an improvement in requirements engineering and framing resulting in higher quality scope definition combined with improved planning and risk management improve procurement management and information transfer, improving design quality and schedule.

This reduces the change associated with the fabrication of independent systems and integration of the independent systems into the SoS during construction. Typical fabrication and construction changes include equipment modifications and site clashes resulting in changes in configuration and requalification of quality assurance and quality control procedures. A consequence of effective interface integration during project development resulting from an improvement of SEM is an improvement in the overall project performance (cost, schedule, and quality). This improves organisational performance in the short term through direct project costs and long-term through a higher performance of the facilities (higher reliability, lower maintenance, and operational costs), improving cash flow, thus reducing the payback period.

The organisation will have financial resources to attract and retain a strong talent pool, provide resources, and fund a regular pool of projects to support the continuous development and sustain a high level of systems engineering performance within the organisation. The absence of a practical development framework has the opposite effect, with all loops forming negative reinforcing loops, causing a downward spiral within the organisational performance. This is directly through cost, schedule creep as well as poor quality of the project. The consequential effect is an immediate negative impact on organisational performance and a long-term effect resulting from the poor performance of the facility (regular breakdowns, higher emissions, lower efficiencies resulting in high energy costs and low production rates). Payback time increases, constraining financial resources that can be allocated to talent retention and the development of new talent. A framework is also essential to act as a screening tool to support recruitment by identifying candidates best suited to succeed in systems engineering roles within the hierarchy.

5 CONCLUSION

This research aims to identify the critical components of ST and SE that influence the development of SEM capabilities to effectively lead large complex SoS projects. The research will be extended to Project Management, Engineering Management and Construction Management fields to analyse performance and identify gaps in Systems Engineering Management capabilities. Findings will be used to develop a framework to support the development of SE and SEM within Organizations responsible for the execution of large, complex infrastructure projects. The emphasis is on improving the capabilities of individuals occupying technical leadership roles, such as Project Engineering Manager within the project work breakdown structure. Findings can also be applied by tertiary institutions looking to design or improve courses intended to enhance competency development for the sector.

Testing and validating the framework will be done through structured interviews. The interview sample will include individuals from various sectors, including client organisations within the mining, energy, and petrochemical sectors and individuals from consultancies providing project services to client organisations. A pool of candidates from the Aerospace and Defense industry can also be considered to provide a basis for comparing the SE tools, systems and approaches applied between the industries. Experienced SE and SEM managers will be considered. Inductive and deductive analysis methods will be used to analyse data collected. The approach should manage bias through triangulation of data sources, analysis methods and sites.

ABSTRACT

Over 1.5 million burn injuries occur in Sub-Saharan Africa each year. Severe burns are one of the most devastating forms of trauma. The management of major burn injuries is complex. Modern burns care has become well-orchestrated with goal-directed actions, including resuscitation, infection control, critical care, wound care, pain management, nutrition support, and psychosocial and physical rehabilitation. Burns pain experience is a complex combination of distress, anxiety, delirium, and situational and emotional factors. Effective pain management is central to optimising outcomes during recovery from burn injuries. Pain management guidelines are published by international bodies regulating burns care. In this paper, systems thinking provides a systemic approach to analysing the complex pain management factors impacting burn injury patients' recovery. This research will implement a conceptual Causal Loop Diagram as an input to a System Dynamics model to simulate the impact of various systemic solutions to pain management.

Keywords: pain, burns care, management, systems thinking

1 INTRODUCTION

Severe burns are one of the most devastating forms of trauma [1]. Studies in 2018 indicated that 1.6 million people in South Africa annually suffer burn injuries, and as many as 3 200 patients require specialised burn care [2]. Cloake et al. [3] state that in South Africa, burns are a significant and urgent public health problem responsible for issues relating to short-term morbidities such as infection and long-term physical and psychosocial disability. Burn injuries are painful, regardless of size and actual or potential tissue damage [4]. The International Association for the Study of Pain (IASP) defines pain as an unpleasant emotional and sensory experience associated with, or resembling that associated, actual or potential tissue damage [5]. Therefore, burn injury pain is a complex combination of distress, anxiety, delirium, and emotional and situational factors [4].

The effective monitoring, management, and treatment of burn injury pain are essential to optimise patient outcomes [4]. The effective clinical management of burn injury pain is underlined by complex pathophysiological mechanisms contributing to the difficulty in pain management [6]. Poorly managed pain can lead to harmful consequences such as prolonged recovery, chronic pain and post-traumatic stress syndrome (PTSD) [7]. Comprehensive protocols can be helpful in pain management [4].

Burn injury pain management guidelines are published by international bodies regulating burns care. The International Society for Burn Injuries (ISBI) released recommendations for burn pain care in 2018. More recently, the American Burn Association published guidelines on pain [8]. The ISBI Guidelines state that each patient should be evaluated individually. Developing detailed unit-specific protocols will reduce complications associated with using multiple agents, optimise patient outcomes, and likely lead to optimal results [4]. A holistic approach and protocols utilising multimodal pharmacological and adjunctive non-pharmacological treatment can optimise burn pain management. However, many barriers exist to improving protocols, like provider bias and inadequate education [9].

Since pain is a complex problem, systems thinking may provide a perspective, language and a set of tools to understand the influences of the various pain factors on patient outcomes and each other. The concept of systems thinking emerged around 1960 as an alternative to linear thinking to understand the dynamic behaviour of complex systems and develop comprehensive solutions [10]. Bertalanffy [11] presented a general system theory with universal applicability across multiple disciplines. Barry Richmond defined systems thinking as the art and science of understanding the underlying structure of systems to make inferences about their behaviour [12]. Senge [13] also described it as a framework for analysing interrelationships between system elements to see the whole better. Today, systems thinking is applied to various fields and disciplines, such as social sciences, engineering, business and management, computer science and medicine, to solve complex problems that are not solvable using conventional reductionist thinking [12], [14].

This paper applies systems thinking to analyse and model the main factors influencing pain management in burn injury patients. A thematic review of recent burns management literature identified the factors and their relationships. These were captured in a Systemigram before identifying a suitable system archetype that describes the observed behaviour. The archetype was used as a template to construct a Causal Loop Diagram (CLD) to help interpret and understand the system's dynamic behaviour.

2 METHOD

Systems thinking is a transdisciplinary field with various tools to improve understanding of the behaviour and structure of a complex system. A transdisciplinarity research field integrates domains that transcend traditional boundaries of the health, social and natural sciences [10], [15]. Systems thinking views complex problems as systems comprising interconnected tangible or intangible components with functions within the system boundary to fulfil a purpose [16], [17]. The interactions between system components and the environment form a complex whole that cannot be derived from observing the parts in isolation. These interactions cause feedback between the elements themselves and the environment, resulting in an emergence that may surprise observers [18]–[20].

“Wicked and messy” problems are technical and multifaceted, including cultural, political, infrastructural and regulatory concerns. This requires multiple perspectives to see the big picture and make connections between and among seemingly disparate events and processes to intervene with high-leverage changes to address the problem [17]. Complexity science can be used in burns care study processes at the cellular, physical, and societal levels as complex systems at different levels [21]. Systems thinking as an integral part of healthcare organisational practices provide reflective dialogue for deep insight to shift entrenched mental models [22].

Systems thinking focuses on the whole system to study its structures and behaviours to understand the deep roots of complex behaviour [12], [17]. Stakeholder mental models describe a system’s structure that causes behavioural patterns [14]. Modelling the structure helps reduce complexity to understanding at different levels of abstraction. The cause-effect feedback loops explain the system’s behaviour. Identifying the patterns and interrelationships can help solve complex problems [23]. Mental models are the implicit structures of meanings, assumptions, beliefs, ideas, and values within individuals that act as inner rules of causal relationships. Systems thinking provides a language and system of holistic (integrative) thinking about systems to represent the mental models [18], [24]. Different systems thinking tools help understand and deal with the complexities of business, economics, environmental, political, and social systems [14]. [14], [20], [25]. Common and repeat problem-causing structures in many environments, situations, and organisations help identify a system’s causal storyline or theory [26].

Senge [13] and Wolstenholme [27] define System Archetypes as free-standing and formal views about system structures responsible for generic behaviour patterns that may be counterintuitive. They are the typical patterns of behaviour due to generic systemic structures in combinations of feedback loops in complex dynamic systems [20], [28], [29]. The archetype provides a high-level story or "fingerprint" of the overall system feedback structure [27], [30]–[32]. A standard set of 10 to 12 archetypes exists for complex dynamic systems [13]. Eskinasi and Fokkema [33] found that using System Archetypes to develop small models can be more effective than using large high-fidelity models to develop solutions to complex problems.

As seen in Figure 1, a typical System Archetype comprises intended and unintended consequence feedback loops. An action for an intended consequence in one part of the system may lead to an unintended consequence in another or outside the system. A delay before observing the unintended result or the system boundary may obscure unintended consequences from observers. The solution minimises the side effects in the two-loop, closed-loop system by removing the system boundary obscuring the side effects [30]. Systems thinkers use archetypes to diagnose complex problems by detecting problematic trends, understanding the system's holistic behavioural patterns, and identifying where to intervene [34]. Leverage points are points of power where a small change can result in a significant system effect [35], [36]. Therefore, archetypes can diagnostically describe the existing system structures and behaviour to support decision-making for future actions [37]. Despite being theoretically weak, System Archetypes are still valuable for communicating system insights with a compromise between simplicity and completeness [30].

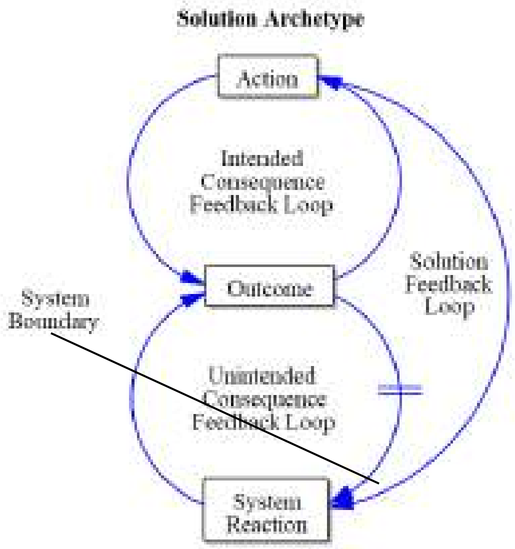

Figure 1: Generic Systems Thinking Archetype

Figure 2 shows a basic systems thinking modelling process that implements System Archetypes [38]. As applied in this paper, the first step is to capture information about the system through a thematic literature survey. Thematic synthesis was used to conduct the literature study [39]. Data were extracted from the available literature regarding burn pain management and analysed. Factors were extracted that influence burns pain management. These factors were combined into themes: pain experience, emotional state, patient satisfaction, patient education, rehabilitation, patient-centred communication, staff knowledge, skill and experience, and dosing.

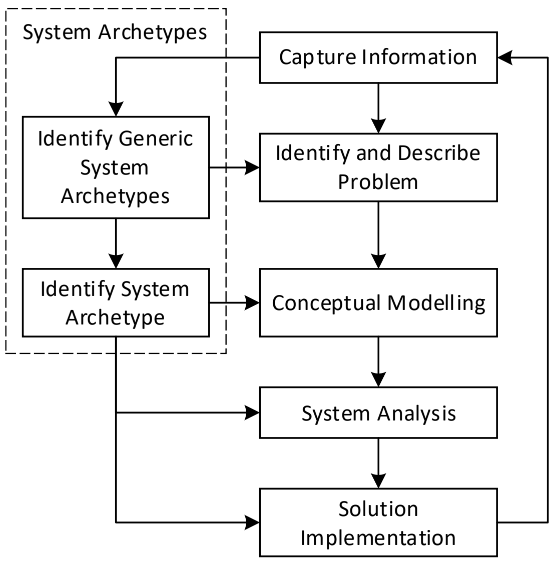

Figure 2: System Thinking Modelling Process using System Archetypes

The retrieved literature is analysed to identify and describe the problem and extract possible issues that cause unwanted or unexpected system behaviour. This paper uses a systemigram as a rich picture to graphically identify the critical variables in the problem situation or system. System Archetypes provide a template or guideline to identify the underlying problematic aspects [30]. Using the identified system archetype, the variables from the systemigram are used to develop a CLD to model the causal relationships and feedback loops. The CLD should include the impact of various interventions with their unintended consequences. The System Archetype helps identify the complex system's variables, interconnectivity, structure, behaviour and possible leverage point(s) to develop a dynamic hypothesis.

3 PAIN

Burn injuries are considered some of the most painful types of injuries. In addition to the pain from the burn injury, its proper treatment is painful and includes wound care, aggressive physiotherapy and surgery. Burns care is multifaceted and changes as healing progresses [8]. The complexity of clinical burn pain management creates a challenging environment in the Burns Care Unit for the multidisciplinary team to manage pain effectively. Pain should be assessed and managed as a collaborative effort, and initiatives that include the Intensive Care Unit interprofessional team can achieve better outcomes [40]. Different themes identified in the literature survey that influence burn pain management are discussed in this section.

3.1 Pain Experience

A burn injury patient's experience of pain is an unpleasant emotional and sensory experience; the experience is complex, and the effects are psychological and physiological [5], [41]. Acute pain occurs immediately after the injury, and the degree of pain is typically related to the depth of penetration of the burn injury into the skin and tissue [6]. The patient's experience of pain is not static. Background, procedural and breakthrough pain exist, and the pain level will vary with care interventions like wound care and rehabilitation [4]. Even when the patient rests, the continuous nociceptive inflammatory process will cause background pain [6].

The patient's pain experience should be assessed during various phases of care and several times daily using pain assessment tools like a patient-self-reported scale. The pain scale should be protocolised and recorded, and staff should ensure consistent language when assessing pain [8]. According to a study by Esfhalan [42], burn patients' pain can be effectively treated and managed with an accurate multidisciplinary pain assessment.

3.2 Emotional State

The burn injury patient's emotional experience and state influence their pain experience and affect pain management. How the patient feels will affect his pain experience. Burn injury pain is a complex combination of anxiety, distress, delirium, and situational and emotional factors [4]. Pain tolerance will be impacted by a patient's mental state [43]. Lang et al. [44] found that anxiety plays a role in the unpleasant emotional response to acute nociception. Post-burn distress must be managed while considering the impact of the emotional factors associated with a burn injury. Neuropathic sensory changes can significantly impact distress, and these changes should be considered and treated as part of burn pain management. Addressing accompanying neuropathic pain can improve burn pain management [4]. Physical damage to the skin of the burn injury patient determines the acute nociceptive response, but it can also contribute to the transition into a chronic pain state [6].

Adverse Childhood Experiences (ACE) play an essential role in the experience of acute pain and the development of chronic pain. Individuals who tend to catastrophise after a burn injury are at risk of acute and chronic PTSD and chronic pain [45]. Burn injury patients with ACE exposure are more at risk for more negative expectations related to pain, greater catastrophising and more significant psychological morbidities [46].

Suffering a burn injury is inherently traumatic, and understanding the patient's trauma history and how it impacts the patient can assist staff in minimising the risk of additional trauma and re-traumatisation [47]. A patient's mental state will impact pain tolerance, anxiety and motivation, and addressing these aspects will facilitate improved treatment [43]. In a study by Duchin et al. [48], multiple patients indicated that their pain experience was more than just physical and reported a greater need for psychological support.

For burn injury patients, the pain may remain an ongoing source of disability long after the recovery period is over [46]. However, long-term psychological issues will be reduced when a burn injury patient’s pain is well-controlled [4]. Burn injury patients’ psycho-affective responses to their background pain include helplessness, anxiety and fatigue [42].

3.3 Patient Satisfaction

It is impossible to eradicate burn injury pain, but when it is safely minimised, patients, families and staff will benefit [4]. Morgan et al. [6] state that given the high incidence of burn injuries and the significant morbidity associated even with minor burns, improved pain management is essential to improve the quality of life of burn injury patients. After healing a burn injury, chronic pain can remain and can have a debilitating effect on the patient’s quality of life. Effective pain management remains a significant challenge.

Stapelberg [49] found that for some patients, the remaining pain memory can be a positive one in which, for example, everyone did their best to help alleviate the pain experienced during dressing changes and after procedures. A study by Keivan et al. [50] demonstrated that religious and spiritual care could help decrease the pain intensity caused by the dressing change and increase the satisfaction of these patients with pain control. The nursing team's continuity in caring for burn injury patients will allow for trusting relationships and bonds to develop. This can improve satisfaction for burn injury patients and staff [43]. The reporting of higher pain scores during hospital admissions can be associated with poorer long-term outcomes and a higher incidence of mental health problems [51].

3.4 Patient Education

Burn injury patients value it when they are included in discussions around their pain management plan [4]. Duchin et al. [48] found that though pain experience can vary, patients are highly interested in improving their understanding of pain and pain-management-related topics. The reported variability in pain experience demonstrated the uniqueness of burn injury pain and its management. Participants highly supported education in pain and a strong desire to understand their pain experiences and care.

Upon admission, severe burn injury survivors often experience pain, anxiety, fear, and uncertainty. Clear, concise information regarding their injury and the treatment plan can reassure the patient and their family. It is essential to communicate the same information consistently throughout the patient’s care [47]. Patients with uncontrolled burn injury pain report it as the worst pain they ever experienced. Studies reported that patients’ satisfaction is closely related to their pain experience and managing that pain [4]. In a study by Duchin et al. [48], patients reported that their pain experience was not just physical and needed pain education, which was most pressing during the inpatient phase of care.

3.5 Rehabilitation

Studies by Dikkema et al. [52] and Lim et al. [53] found that early mobilisation of patients with burn injuries is essential. However, the pain was noted as a barrier to early mobilisation. Patients with uncontrolled burn injury pain have a diminished capacity to participate in rehabilitation [42].

3.6 Nurse-patient Communication

Tetteh et al. [54] found positive results of effective nurse-patient communication to be early detection of a patient’s distress, helping a patient manage pain and improved patient participation in their care. They also found that poor nurse-patient communication results in poorer cooperation during care activities and reduced endurance to pain. Discussions with the patient are essential when setting accurate and individualised goals for an effective pain management plan [4].

3.7 Staff Knowledge, Skill And Experience

Quantitative changes in the patient's pain response to pain management can be observed when pain severity is assessed [44]. The repeated use of pain scoring systems and tools during all phases of burns care enables monitoring the adequacy of pain control. This can ensure optimal pain management. Staff needs to be well-trained to apply pain tools appropriately [4].

A study by Tetteh et al. [54] found that due to the subjective nature of pain, the need for increased communication for a practical assessment and management of pain among patients with burns is highlighted. Therefore, nurses must be well-trained in communication, emphasising patient-centred communication.

Burn centre staff should be trained in burn management [1]. Burn injury patients can receive the best possible acute and long-term care when highly specialised personnel work together in a customised facility with readily available resources [43]. The skill of understanding that burn injuries are inherently traumatic and that the patient's prior trauma and the impact it has on the person can minimise the risk of vicarious traumatisation in staff [47].

3.8 Dosing

The minimum effective dose can be administrated when the measurement of burn pain is accurate. This will facilitate minimising medication-related complications. Under- and overmedication can be avoided when monitoring and adjusting therapy optimises pain control. Practitioners should be aware that all medications have adverse effects and monitor for these effects. Medication choice and route adjustments may be necessary [4].

Despite our increased understanding of the mechanisms involved in the recovery phases, the chronification of burn pain and the effect of pain and suffering on the patient's long-term outcomes, pain management in burn injury patients remains challenging [49].

4 SYSTEMS THINKING MODEL OF PAIN MANAGEMENT

Table 1 presents the systemic analysis of the literature on burns pain management. The matrix cells provide the literature supporting the relationships between the pain management elements. The Systemigram in Figure 3 graphically describes the "story" from the literature study on burns pain management. The nodes in a systemigram are nouns or noun phrases from the themes or factors. Relationships between the factors are represented as arrows, with the verbs and verb phrases from the text description. The principal subject is placed in the top left corner, and the object in the bottom right corner of the Systemigram. A Systemigram helps to identify the system's motivation, management, failure, and remedy. Many people admire a finished Systemigram but fail to appreciate the many failed preceding attempts and failures containing the seeds of eventual success. These defects should not be regarded as problems to be fixed but rather as opportunities to better understand the message of the systemic description. Getting interdependencies correct while adequately portraying the themes can call for a rework of what otherwise looks like the perfect picture [55].

In figure 3, patient-centred communication with a closed-loop feedback structure is essential for patient education. Communication is critical to educating the patients about the protocols and procedures for managing burns pain. Equipping staff with the required knowledge, skills, and experience improves communication and patient education aspects.

Table 1: Pain Management Element Interaction Matrix

Effect / Cause	Pain Experience	Emotional State	Patient Satisfaction	Patient Education	Rehabilitation	Patient-centred communication	Staff Knowledge, Skill & Experience	Dosing
Dosing	[4]		[4]					
Staff Knowledge, Skill & Experience			[1], [4], [43], [47]	[54]		[54]		[4]
Patient-centred communication			[8], [54]	[4], [47]				[54]
Rehabilitation	[4], [7], [52], [53]							
Patient Education						[4], [47]		
Patient Satisfaction		[4]			[51]			
Emotional State	[43], [45]				[42], [43], [46]			
Pain experience			[6], [7], [48]		[7], [43], [52]			[4]

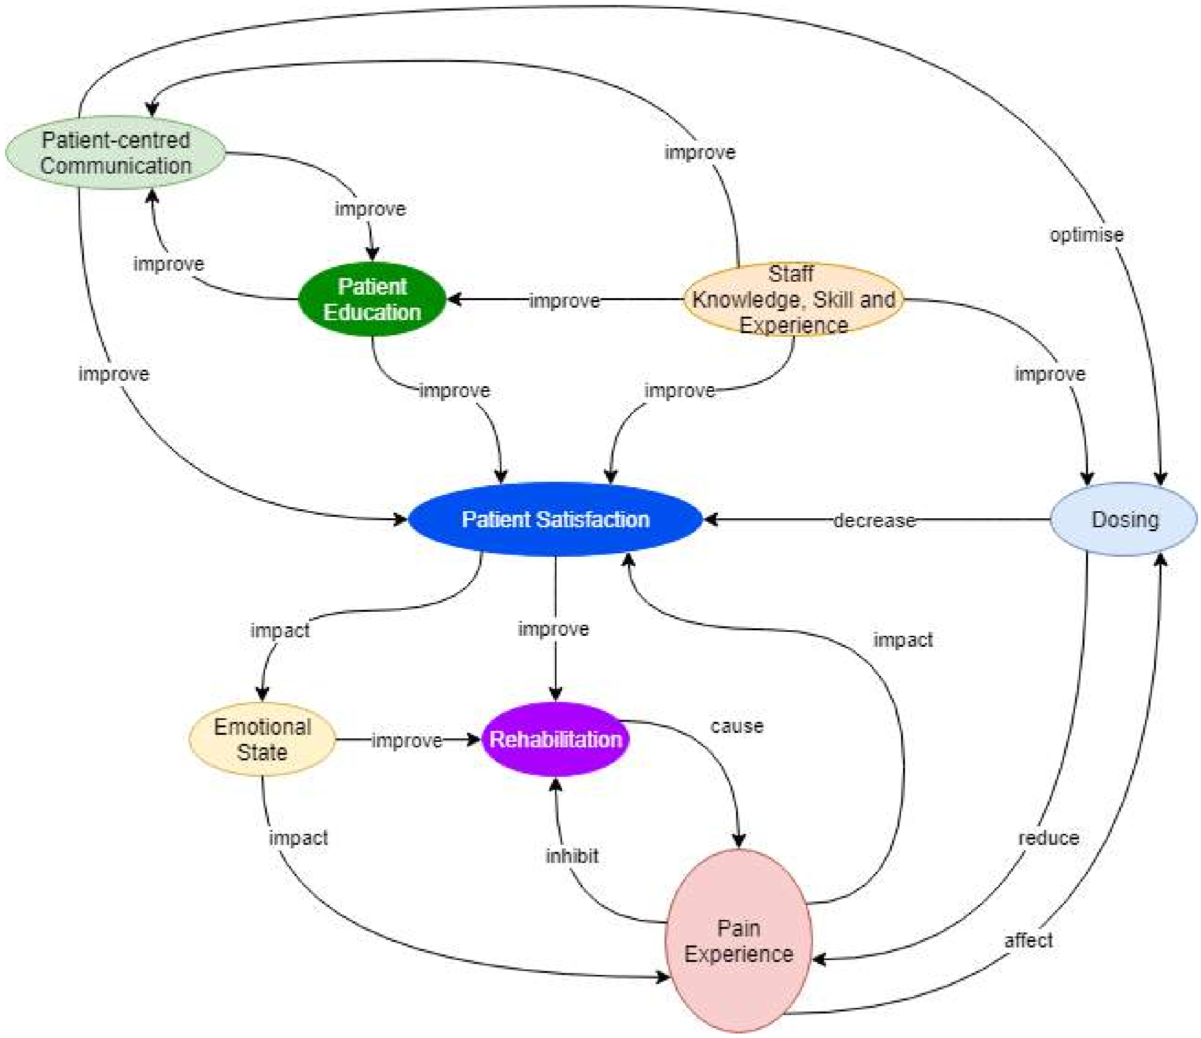

Figure 3: Systemigram for pain management

Patient-centred communication, patient education and staff knowledge, skill and experience factors positively impact patient satisfaction. However, dosing may have some adverse short-term and long-term effects as a method of managing pain with medicine. Improving patient satisfaction also improves the journey of rehabilitation, which in turn may increase the pain patients experience. This increase in pain inhibits the progress of rehabilitation. Another critical element in the system is the emotional state of patients, which can improve rehabilitation and the experience of pain. Even though there seems to be a direct feedback link from the emotional state to patient satisfaction, this is achieved through the improved experience of pain. The negative impact of pain on the emotional state is also realised through patient satisfaction in this Systemigram through the larger feedback loop. The "story" the Systemigram tells can guide the identification of a System Archetype.

The System Archetype chosen for this problem is "Shifting the Burden," which illustrates the tension between implementing a relatively easy solution aimed at the symptoms rather than a fundamental solution that addresses the underlying problematic structures [28]. As seen in Figure 4, implementing long-term solutions demands a deep understanding of the underlying problem and takes time. The symptomatic solution is easier to formulate and solve to produce instant gratification without paying attention to the underlying and fundamental systemic problem. The symptomatic solution reduces the problem symptom and alleviates the need to implement a fundamental solution.

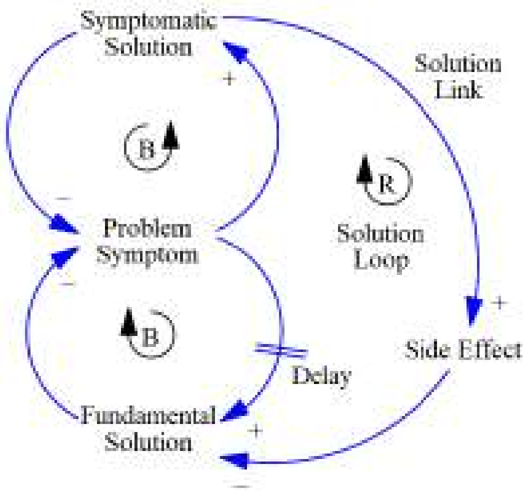

Figure 4: Shifting the Burden

Figure 5 presents the CLD for burns pain management as derived from the systemigram in Figure 3 and based on the "Shifting the Burden" System Archetype from Figure 4. In the context of this paper, the problem symptom is the "Pain Experience" of the burn patient. The symptomatic solution is "Dosing," which is administering medication to control the pain experienced by patients. The fundamental solution is chosen as "Rehabilitation" to enhance the patient's journey to recovery. "Patient Satisfaction" is a side effect as overusing medicine to control pain may have long-term side-effects such as dependency issues.

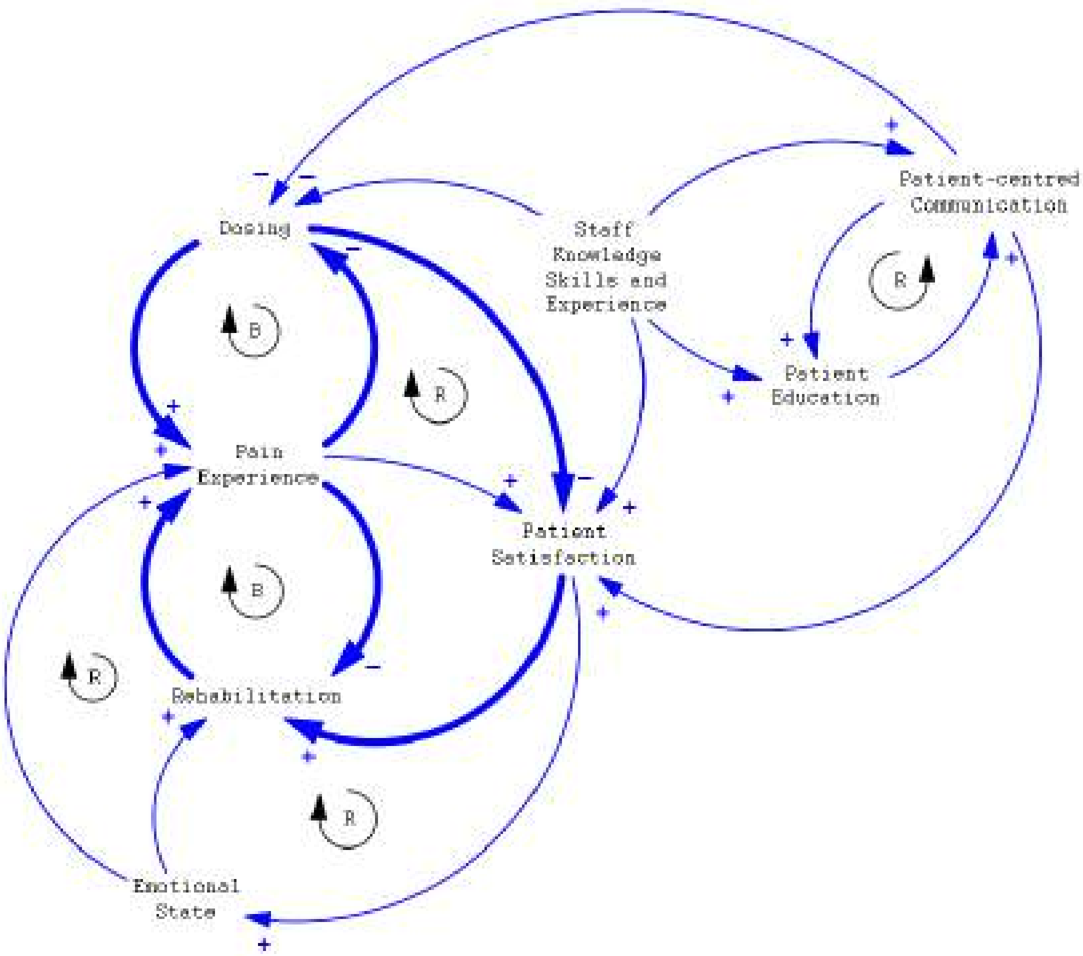

Figure 5: Archetype for Shifting the Burden in Pain Management

Burn injuries are considered some of the most painful types of injuries [8], and managing pain at an acceptable level for these patients is complex. Developing a systems thinking model clarified the relationships between the different and interconnected elements that influence the management of burn injury pain. This model can improve understanding and increase the burn care teams' insight into managing burn injury pain. Improved understanding can lead to improved management and the minimisation of pain. Burn care teams can implement a multimodal approach to pain management utilising this systems thinking model where small interventions can have significant results. It is impossible to eradicate burn injury pain, but when it is safely minimised, patients, families and staff will benefit [4].

5 CONCLUSION

Implementing systems thinking to manage pain experience in burn injury patients involves considering the interconnected elements and dynamics of the system that contribute to their experience of pain. Viewing pain as a system helps understand the interaction of physiological, psychological, and social aspects contributing to pain perception over the burn wound life-cycle of stages, including the acute phase, wound healing, and long-term rehabilitation.

Creating a visual representation or diagram to map the relationships between the different system elements helps identify and interpret the cause-and-effect relationships, dependencies, and interactions. Identifying the feedback loops within the system enables understanding the possible counterintuitive outcomes.

Understanding the dynamic system behaviour may identify leverage points where small interventions can lead to significant changes. These leverage points can be targeted to manage burn injury pain effectively to improve patient experience through targeted medication protocols, enhancing patient education on pain management techniques, or improving communication between healthcare providers and patients.

Recognising the burn pain management system's boundaries must consider the more extensive healthcare system, policies, resources, and cultural factors that impact pain management practices. Engaging all burn pain management stakeholders may encourage collaboration and information sharing to understand the pain experience better and develop comprehensive multimodal pain management strategies.

ABSTRACT

To explore effective maintenance models that have been applied in the industry. Maintenance models were identified from 2010-2023 studies (45) that met inclusion criteria. This was done by applying general Systematic Literature Review and Thematic Analysis Framework. Key relationship between maintenance strategy and company performance have been outlined. Majority of the studies were in the manufacturing and energy sectors. Chinese were the leaders in maintenance model research. Thirty-seven (37%) made use of preventive, prescriptive (13%), maintenance 4.0 (2%) and opportunistic maintenance (7%). Thirty-three (33%) made use of artificial intelligence. Maintenance data analytics based on artificial intelligence promises the maintenance practitioners deeper insights and foresights. Maintenance models in this study lacked success scores hence authors subjectively evaluated the relevant models for power plant setup. Research output in this sector had an upward trend between 2010-2022. These learnings shall be applied in the development of plant maintenance model in the future.

Keywords: Maintenance, Systematic, Model, Techniques, Uptime.

* Corresponding Author

1 INTRODUCTION

According to EPRI [1] the goal of maintenance is to do the minimum amount of maintenance that guarantees maximum plant reliability. Maintenance function is a sub-system of an industrial organisation, with the function of planning, adjusting, repairing, replacing and modifying the parts of the plant that should be able to perform its specified function over some specified period ([2] and [3]). Maintenance function is therefore one of the discrete building blocks that serve to provide competitive advantage in an organisation. Its management is charged with the responsibility to maintain the plant operational at all times so that the customers' expectations can be exceeded. The top-down relationship between this functional strategy and the organisational goals are depicted in the figure 1 and 2 below.

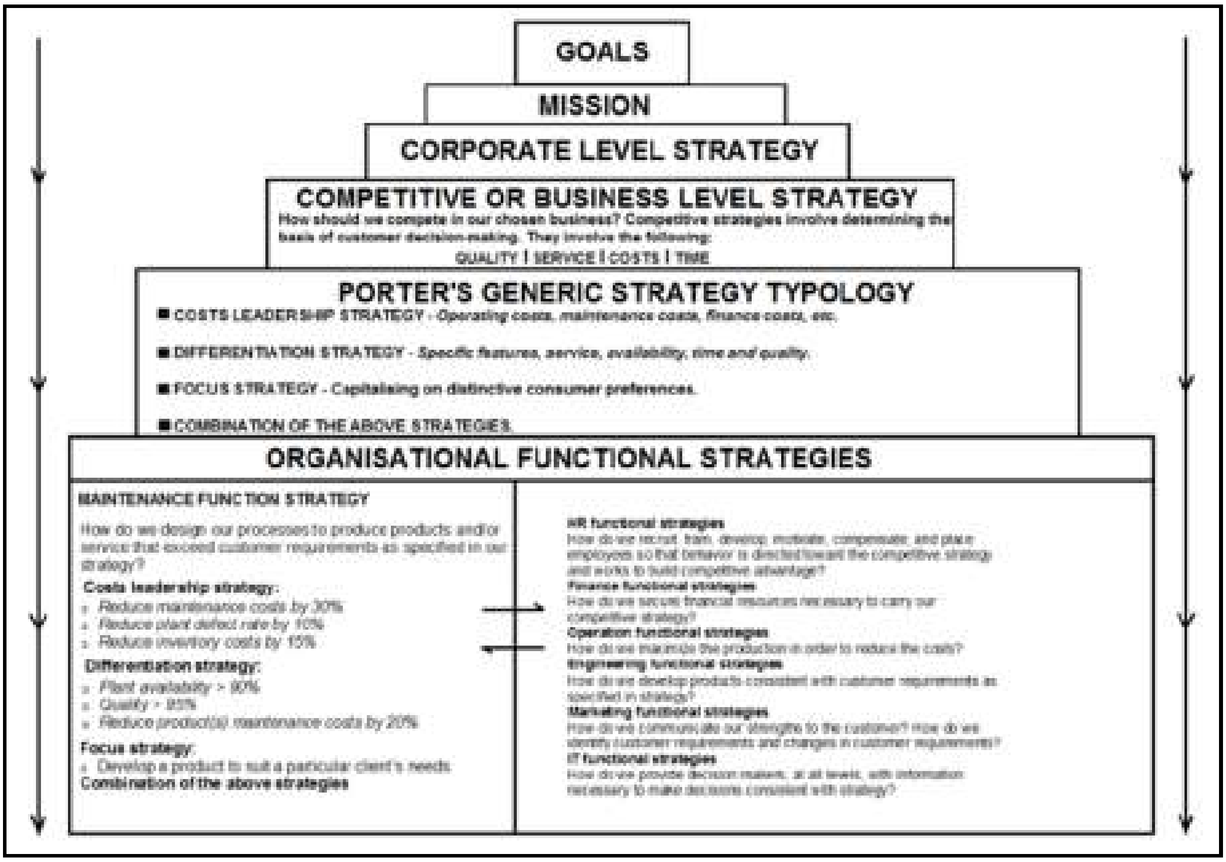

Figure 1: Organizational goals and maintenance functional strategy relationship.

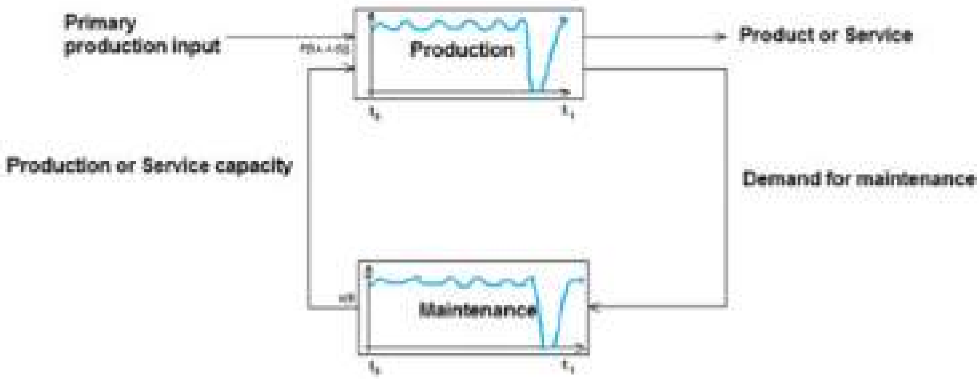

Figure 2: Production-Maintenance relationship. Source: Adapted from Gits [4] and Ben-Daya *et al*. [5].

In this study, systematic literature review (SLR) shall be conducted on the maintenance model studies with the objective to transfer the learnings from the best model to the dust and ash system in a coal-fired power plant in the future.

2 RESEARCH OBJECTIVE

The researcher was tasked to improve the health of the dust and ash plant in a coal-fired power plant and a requirement was identified to explore the other maintenance models in the literature. Maintenance is one of the functions that play a critical role for the best plant uptime (see figure 1). Therefore, the objective of the study is to find attributes that make maintenance model to be successful through systematic literature review by identifying themes that stand-out. The results of this study shall be utilised in building the maintenance model through system dynamics tool in the future.

3 RESEARCH QUESTION

Based on the stated background, systematic research methodology has been adopted to find out the best features that can be adapted in the power plant for an enhanced plant uptime. This study seeks to answer the following question:

- What are the key attributes used in the general maintenance model literature to achieve increased plant uptime?

The study shall characterise the studies by *industry sector, country and continent, maintenance strategies, scientific techniques applied in models, type of publication, impact of the model on plant uptime and research trends*. The results will also be used to conduct benchmarking project within the industry in the future.

4 RESEARCH METHODOLOGY

By using a general internet search in academic websites for pertinent journals, conference papers, theses, and books - systematic literature review (SLR) methodology was applied to find the best attributes in the maintenance models. In order to summarize and evaluate the findings, characterize the attributes of the maintenance models, and emphasize factors that made a model to deliver improved plant uptime, data was then coded and extracted from the included studies. In this work, about 45 maintenance model items were mapped.

A well-defined and repeatable search approach was used during the investigation process, and studies were either included or rejected based on the inclusion criteria.

The benefits and shortfalls of this methodology were known; hence research controls were put in place to remove bias. The ability of this study was to explore several maintenance investigations cases from various socio-cultural contexts and present a holistic view as its main strength. The articles were selected by the author by using key word like “maintenance model”, this could be a source of bias as some of the studies were excluded and others included based on the article contents. In addition to its strength, there were a few limitations to be mindful of. Researchers offered country-specific maintenance sector scenarios, but these were open to their own interpretation and might be subjective [6].

5 SEARCH STRATEGY AND SELECTION PROCEDURE

General internet search through database has been used for assessing and reporting the maintenance modelling research data, to identify special attributes that made a specific model to have a positive impact on plant uptime. The research methodology that was implemented was combination of manual article selection and steps as outlined in figure 1 below. The search google scholar engine made use the following search string: *maintenance model*. Total of 45 articles were identified for the systematic review, the authors made use of probability sampling method where researchers select members of the population at a regular interval to select the final articles to be included in this review, a practical screening was conducted, this was based on the setting of inclusion criteria and flow diagram in figure 3.

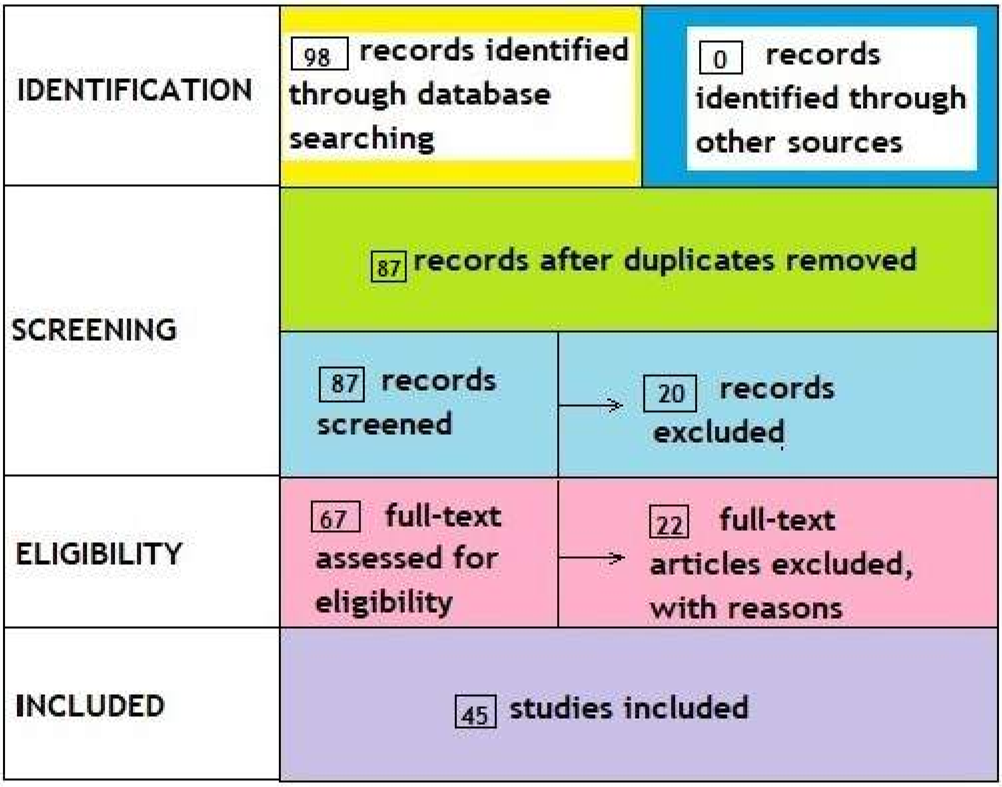

Figure 3: Systematic review flow diagram. Source: Adapted from [7].

6 INCLUSION CRITERIA

The initial search yielded 898 records through general internet search on the 30th April 2023. Sampling was based on: 1st ;10th; 19th ;28th ;37th ;46th ;55th ;64th ;73rd and 82nd web pages as per google scholar search results and each page contained maximum of 10 articles. The 800 records were excluded as a representative sample was obtained. Systematic sampling was provided the author with 98 studies. Figure 3 above provide further details regarding the screening and filtering that was applied as per inclusion/exclusion criteria (Table 1). Only English studies were selected (Table 1). Studies were included if they were published between 2010 and 2023. This included 45 journal articles, books, theses, conference papers and technical reports. This process was followed to assist the peer-reviewers to able to easily establish the replicability of this study for confidence building in the research outcomes [7]. The studies covered maintenance models that could have positive impact on plant uptime project to be conducted in the future.

Table 1: Inclusion criteria

Item	Description
Database searched	Google scholar
Date of search	1st May 2023
Person searching	Sello David Koloane
Database settings	Open to all areas that had researched about maintenance models in the industry

Item	Description
Language	English
Timespan	2010-2023
No. of records obtained	45
Search string	"maintenance model"
Questions	**Review focus**
Population – who?	Maintenance models of the industry in general industry and internationally.
Intervention – what?	Maintenance model that had positive effect on plant uptime. *The objective of these strategy is to eliminate the dust and ash plant unplanned maintenance and increase its uptime*.
Comparator/s – compared to?	Best industry with high uptime locally and internationally.
Outcomes – expected result	Identification of the maintenance model levers that are responsible for high plant uptime.
Setting – where?	In any general industry setup

7 STUDIES SELECTION

The double filtration procedure employed in this inquiry was used to filter the 45 articles that did not meet the inclusion criteria. All of the articles that had complied with the standards were reviewed and coded using qualitative data analysis to identify the relevant themes.

Braun and Clarke [8] posit that '*thematic analysis is a method for identifying, analysing, and reporting patterns (themes) with data*'. The following themes were adopted: *industry sector, country and continent, maintenance strategies, scientific techniques applied in models, type of publication, impact of the model on plant uptime and research trends.* This was the finale of a six-step procedure, as seen in figure 4 below.

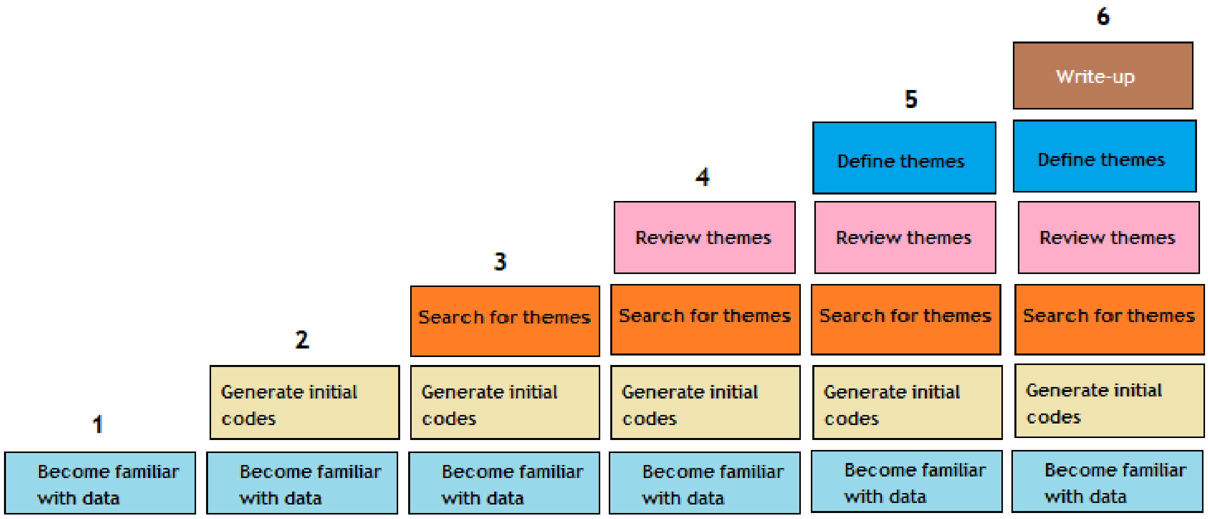

Figure 4: Framework for doing thematic analysis. Source: Adapted from Braun and Clarke [9] and Maguire and Delahunt [10].

The results of the maintenance models thematic analysis have been listed under appendix A ([17]- [59]). This refers to the key attributes used in maintenance systems to achieve excellent plant results in the general engineering industry (RQ). During the application of the research method, it became evident that the studies were not well structured, maintenance systems that were applied to address the plant issues were not the same, for this reason and others, meta-analysis could not be applied as the studies were heterogeneous and did not meet PRISMA guidelines requirements.

8 STUDY CHARACTERISTICS

In an attempt to answer the research question, 45 maintenance articles were initially studied without specific themes of interest. Thereafter, top 6 themes that stood out in the ‘best maintenance model’ were characterised and analysed.

8.1 Industry Sector

The majority of the studies (44%) that were reviewed did not indicate the sector that their maintenance models were based upon (figure 5). This posed a problem for the maintenance practitioners that were seeking for solutions to address their maintenance problems as they did not know if the model was applicable to their respective industry. The industries that were found in the studies include the following (refer to appendix A for details): Energy (16%), Manufacturing (13%), Port (5%), Road network (5%), Transport (4%), Building (4%), Rail (2%), Semiconductor (2%), Aviation (2%), and Defence (2%). These sectors were found to be relevant to the dust and ash system with the coal-fired power plant as the learnings can be adapted. Figure 5 below provide a detailed breakdown of the sectors that were represented in this sample.

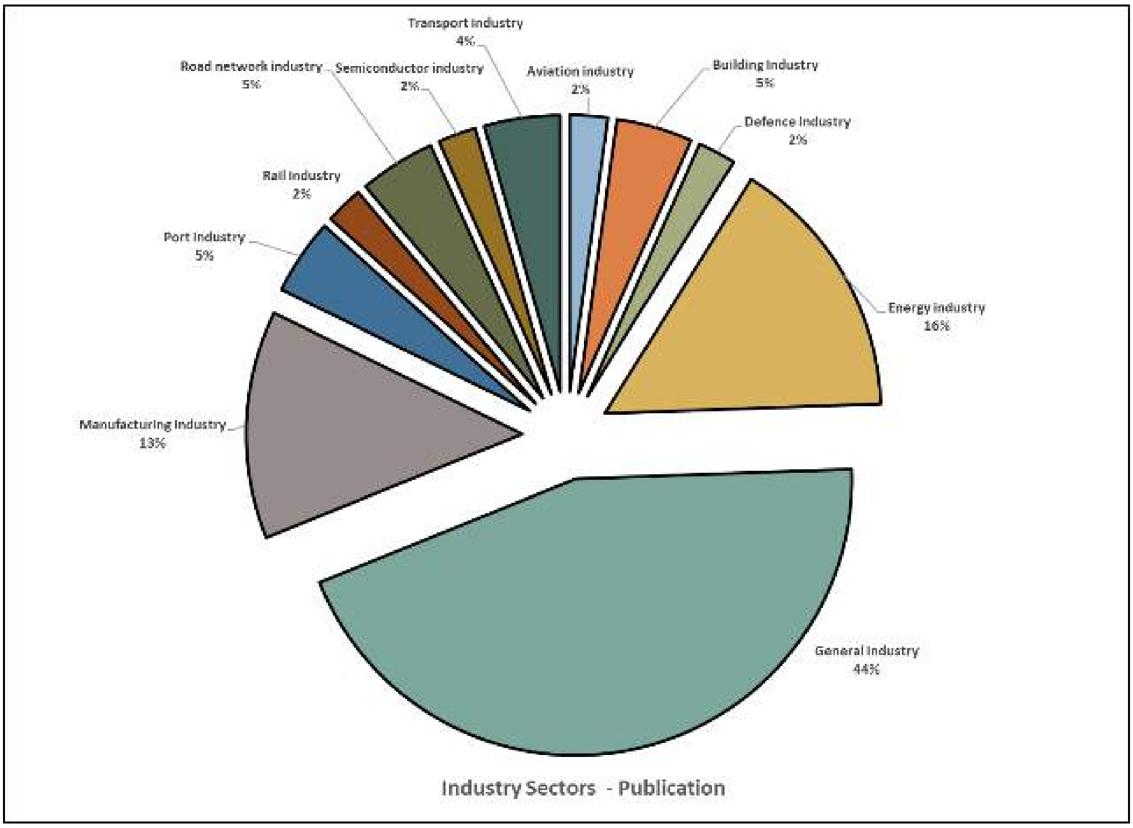

Figure 5: Industry sectors in the studies under review.

8.2 Authorship analysis by Country and Continent

Most of the studies (40%) were based on the research work that was conducted by the Chinese academics. This was followed by the French research studies (7%), the gap between these two nations could perhaps be explained through the population dynamics of these nations. Malaysia had 4% of the studies in the sample. South African researchers contributed 2% of the research work based on this sample and this indicated a need for more local research that can be easily transferred to the industry. Low number of the South African authors in this sample is an indictment as unique South African maintenance problems did not receive the attention of the academia. There is a need to cultivate the academia-industry collaborations so that South African plants maintenance performance can exceed the world class standard if products or services are to continue to be globally competitive. Figure 6 below provide proportions of the countries that were actively seeking solutions for their plant maintenance problems.

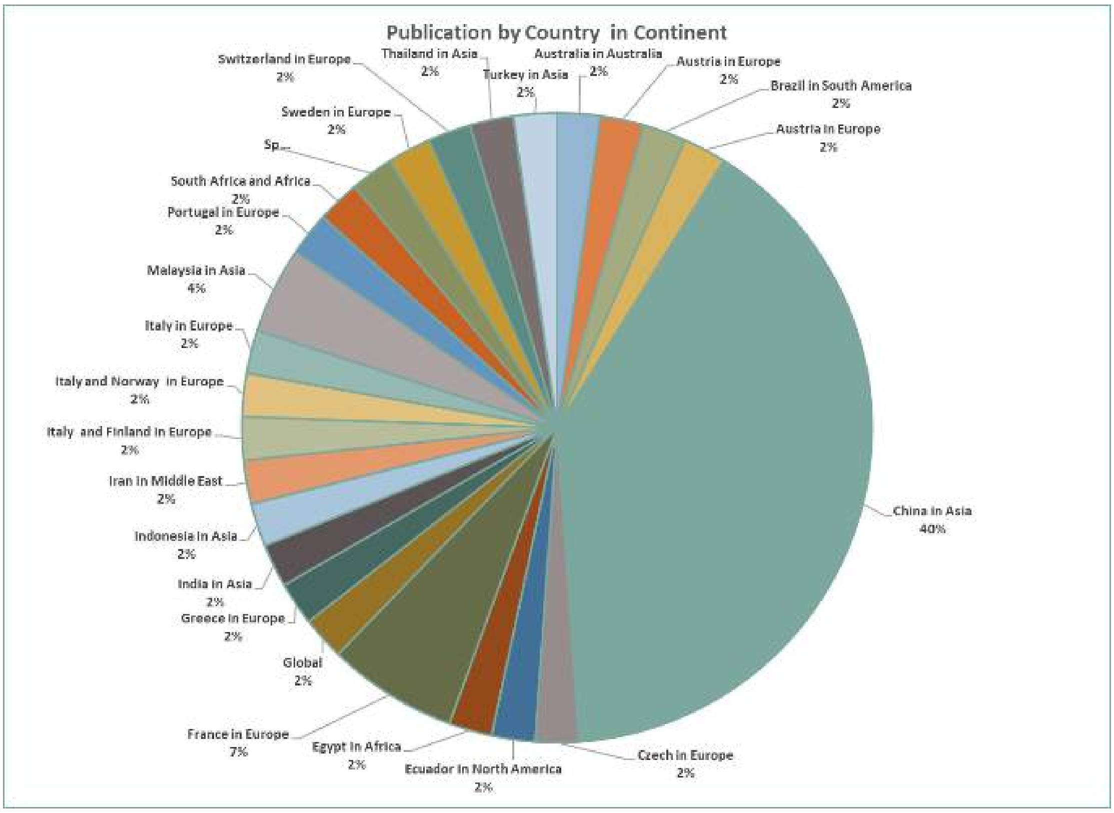

Figure 6: Authorship by country and continent in the studies under review.

8.3 Maintenance Strategies

Najimn, *et al*. [11] defines the maintenance strategy as a decision rule which establishes a sequence of actions to be undertaken with regard to the operation state of the considered system in a plant. According to Nowlan and Heap [12] these include corrective maintenance strategy, preventive maintenance strategy, predictive maintenance strategy and prescriptive maintenance strategy [13]. Figure 1 and 2 has highlighted the dynamic relationship between *Company strategy (CS - x), Maintenance Functional Strategy (MFS - y), Plant Maintenance Strategies (PMS - z) and Company Performance (CP - F)*. Therefore, company performance can be described by the hypothetical model under figure 7.

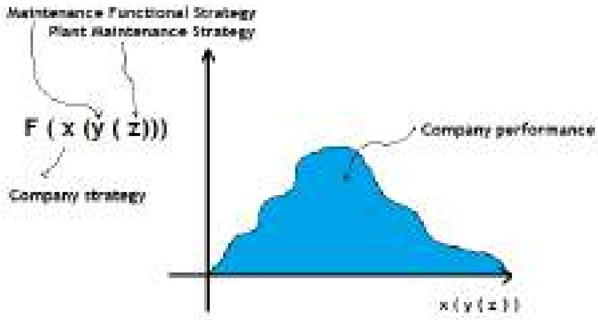

Figure 7: Hypothetical company performance relationship with plant maintenance strategy.

Strategies (z) that were identified in the studies included some of the following: *Age-based and condition-based maintenance, Maintenance 4.0, Opportunistic maintenance, Predictive maintenance, Prescriptive maintenance, Corrective maintenance, Preventive maintenance, Predictive maintenance and Self-maintenance.*

In these studies, most of the articles (37%) had designed their maintenance models to be geared to preventive maintenance for safer and higher performing systems. Prescriptive (5%), Maintenance 4.0 (2%) and opportunistic maintenance (7%) were strategies that were not applied in the dust and ash plant and student will research further on these topics with the objectives to identify possible application in the future. Breakdown of the maintenance strategies that were identified in the studies is shown below under Figure 8.

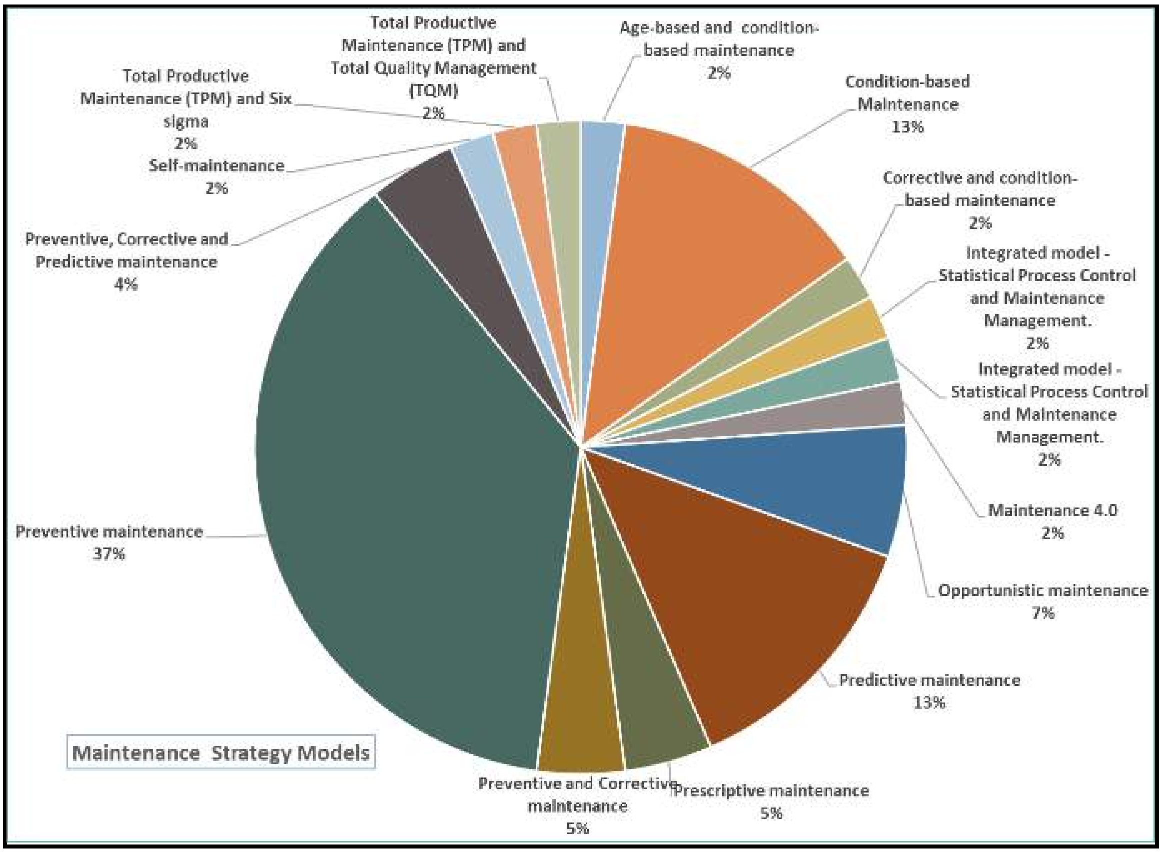

Figure 8: Maintenance strategy adopted in the maintenance models under review.

8.4 Scientific techniques/Theories that were applied in the studies

Table 2 below list the scientific techniques that were identified in the studies. These included the use of *applied advanced mathematics, algorithms, advanced statistics for data analysis and artificial intelligence (AI) for plant maintenance management*. Chief amongst these tools was the application of the artificial intelligence in plant maintenance, Rojek, *et al.* [14] conducted a study on improving maintenance and supervising the machine failures through the application of the artificial intelligence. In this study, they found that "effective use of preventive maintenance requires *large amounts of reliable annotated sensor data* and *well-trained machine-learning algorithms*". These items will have to sourced prior to the implementation of the AI in the power plant. Matlab was the most common software tool used to mimic or simulate the real maintenance model. Table 2 below has comprehensively covered the techniques/theories that were identified from the 45 studies.

Table 2: Scientific theories or technologies or techniques that were applied in the maintenance models under review (Appendix A1-45).

Risk based opportunistic maintenance (RBOM) model. Global optimization algorithm. Monte Carlo simulation. Weibull distribution [A1].	Advanced mathematics and statistics [A8].	Advanced Mathematics. Delay-time-based PM models. Algorithms [A15].	Quasi-Monte Carlo method. Kalman filter. QMC method. DG method to simulate degradation data and maintenance data. Kalman Filter. Intelligent flexible pavement deterioration and maintenance management model. Artificial Neural Network (ANN). Regression analysis [A33].	Self-healing mechanism. Wireless Sensor Network (WSN). NS2 simulator. Effective Fault Detection and Routing (EFDR) [A40].
Deep neural networks (DNN), recurrent neural networks (RNN) and regression random forest (RRF) [A6].	Gaussian degradation process. Semi-regenerative theory. IG degradation process [A13].	Principal Component Analysis (PCA), Statistical Pattern Recognition (SPR) [A20].	Lean Root Cause & Defect Analysis (LRCDA). Root Cause & Failure Analysis (RCFA) technique. Lean Maintenance and Total Productive Maintenance (TPM). Fishbone analysis. Pareto analysis [A27].	Regression model for maintenance planning and prediction. Questionnaire survey, interview and case study. Statistical Package for Social Science (SPSS) software [A34].	Advanced mathematics [A41].
Multivariate Gamma subordinators as degradation model. Artificial intelligence [A7].	Monte Carlo simulation. Opportunistic maintenance model [A14].	Quasi-Monte Carlo method. QMC method. DG method to simulate degradation data and maintenance data. Kalman Filter. Non-stationary Wiener process [A21].	Maintenance 4.0 model. Predictive maintenance based on recent research are Physic, Data-driven, Probabilistic, Stochastic and A.I.-method based. Prescriptive maintenance and analytics. Prognostic maintenance [A28].	Ordinary differential equation (ODE) model. Stochastic process theorem. Newton-Raphson iterative method. Weibull proportional failure model. Euler Method [A35].	Weibull distribution. Rough set theory [A42].
Proposed Model within the Paradigms of SM, CE, and Sustainable Maintenance. Matlab software [A43].	Integrated Autonomous Production Control Mode. Optimization algorithm [A44].	Reliability Block Diagrams to Fault Tree Circuits [A45].	N/A	N/A	N/A

Learnings obtained from this section has been summarised under Table 3 below.

Figure 9 below represents a list of maintenance models that the authors deemed them to be suitable for the dust and ash plant maintenance problems. These models (see table 2 above) were subjected to subjective assessment with reference to the dust and ash plant application by the researchers and the ratings were as follows: score of 1 indicated NOT CONSIDERED, score of 2 indicated CONSIDERED and score of 3 indicated as TO BE TESTED. Below in figure 9 is the results of this evaluation of the maintenance models.

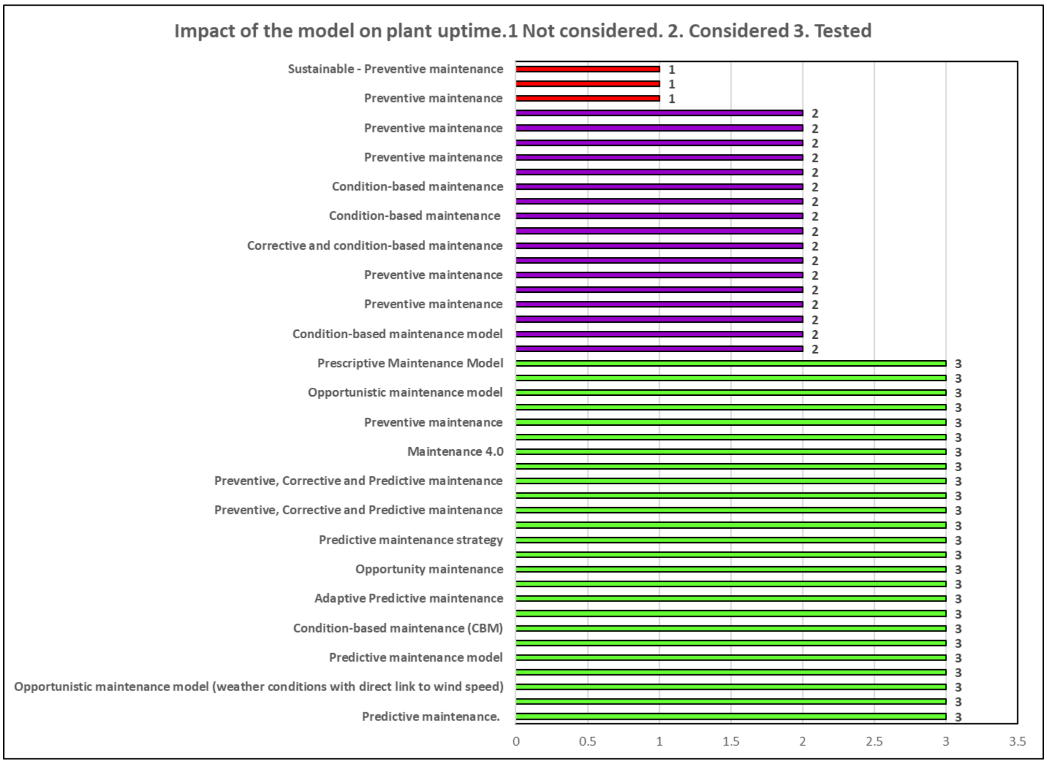

Figure 9: Subjective assessment of the maintenance models' impact on the dust and ash plant uptime by the authors.

- Maintenance strategy models (7%) were subjectively deemed to have no positive impact on plant uptime. This was two preventive models and TPM/six sigma model.
- Maintenance strategy models (35%) were considered to have the potential of positive impact plant uptime.
- Maintenance strategy models (57%) were classed to have positive impact on the plant uptime.

8.5 Type of Publication

Publications in this study was made-up of conference (11%) and journal papers (89%). The leading publication (20%) was the Journal of Reliability Engineering and System Safety. The nature of these papers was that of academia-industry collaboration with the objective to dissect the practical maintenance challenges in the laboratory using academic scalpels through the academic lenses. These joint ventures provide the industry with the benefits of cutting-edge research and highly skilled graduates to solve real maintenance problems [15]. These articles were of high quality, they have been subjected to rigorous peer-review mechanism and published in the internationally recognised academic publication. Figure 10 below depict the type of publications that were used to report the research results of the academia, industry and academia-industry collaboration.

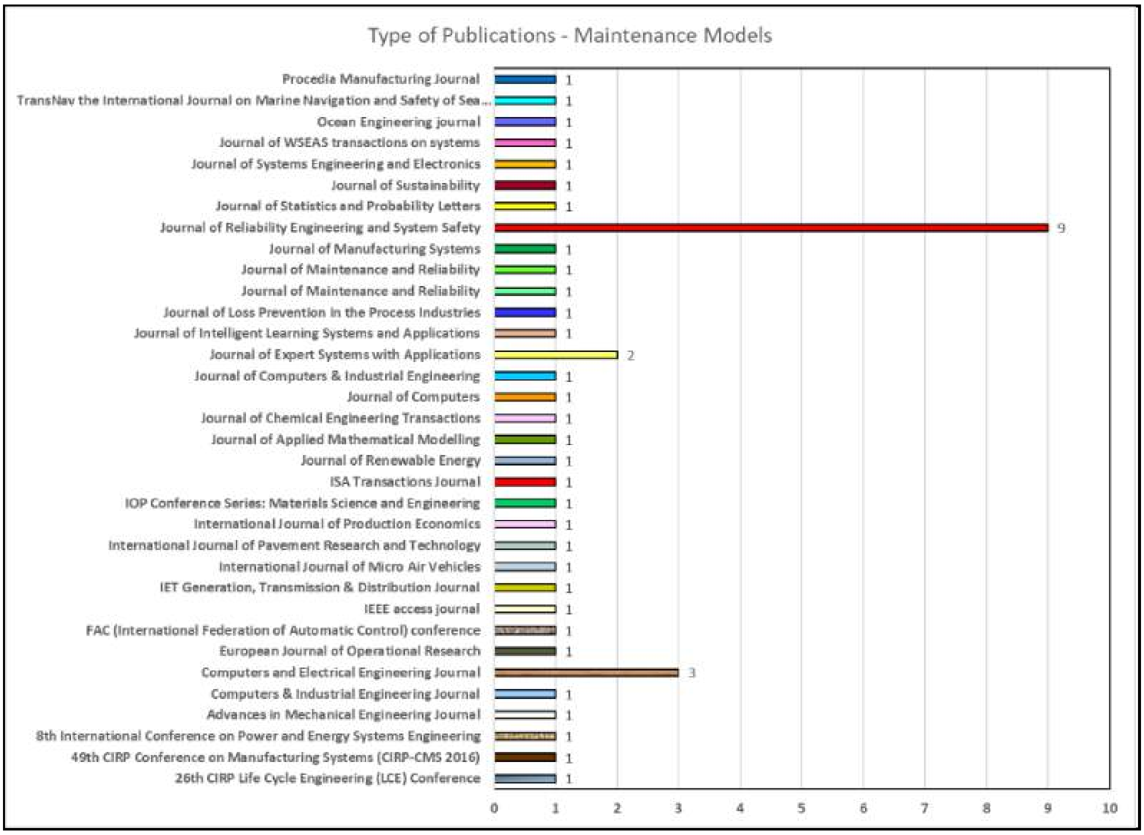

Figure 10: Type of publications in the maintenance model studies under review.

8.6 Number of Maintenance Models Publications per Year

Maintenance models publications (see figure 12 below) indicated an upward trend (2010-2022) and this highlight the importance of the maintenance in the industry in general as more and assets owners realise the relationship between sustainable business profits (figure 1) and the plant health relationship ([4] and [5]).

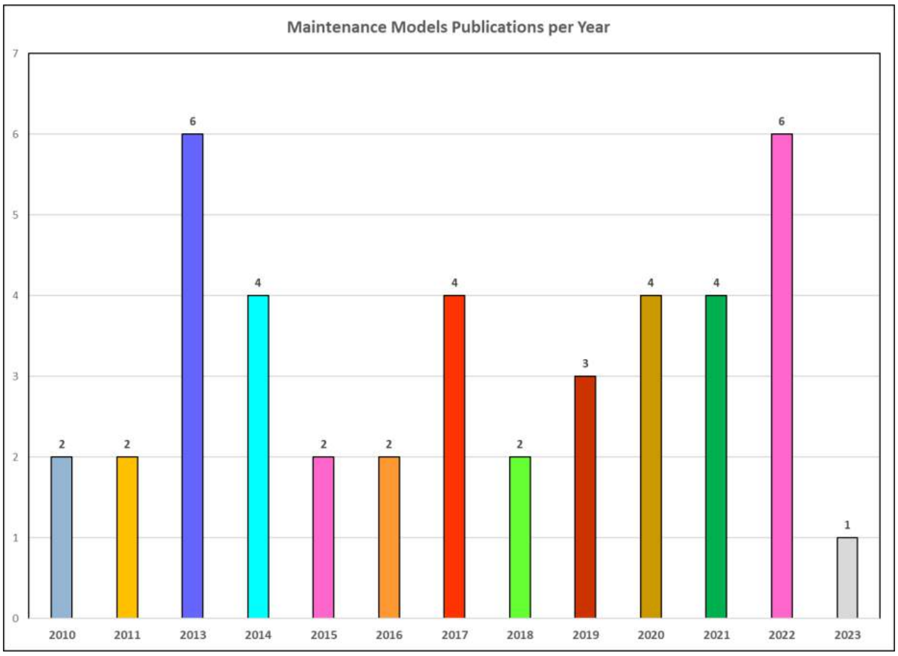

Figure 12: Publication trends in the studies under review.

9 DISCUSSION OF THE RESULTS

Table 3 below provide a summary of the systematic literature review and learnings that are important for the maintenance practitioners.

Table 3: Discussion of results for maintenance models in the studies

Item	**Study findings**	Notes for power plant maintenance practitioners
Maintenance strategy (Section 8.3)	Relationship between maintenance functional strategy, maintenance strategy and company strategy were synthesised based on the general structure of the maintenance functions in the industry and work of Porter [3] on strategy. Gits [4] and Ben-Daya *et al*. [5] work have also demonstrated the value of maintenance in the company. Preventive maintenance was the most common strategy (37%). Maintenance 4.0, Opportunistic maintenance, Prescriptive, Predictive and Self-maintenance strategies formed part of the 21st century innovation and these did not form part of the dust and ash plant maintenance strategy.	Maintenance function is critical for the success of the company. Figure 1 - Maintenance functional strategy model developed by the authors can be used by the maintenance practitioners to justify funding for the maintenance capital projects. This is essential as certain company managers continue to treat maintenance function as a necessary evil. Preventive maintenance remained a vital cornerstone for plant maintenance management. Power plant practitioners to incorporate these innovative strategies in their maintenance management so that plant safety and uptime could be enhanced. Maintenance 4.0 to be prioritised so that plant health can be enhanced. Opportunistic maintenance strategy was found to be applicable to dust and ash plant, but it has to be further researched as literature covering this topic was scarce perhaps due to its nature as it is occurs based on stochastic factors.
Industry sector (8.1)	Significant number of the articles (44%) did not mention the industry sector that their maintenance models were based upon. Energy, Manufacturing, Port, Road network, Transport, Building, Rail, Semiconductor, Aviation and Defence were the industry sectors that studies were based upon. The largest single sector was energy (16%), this was applicable to the power plant and thus it could be easily benchmarked. This confirmed the prevalence of maintenance activities across these sectors.	Researchers must cite the industry sector so that their maintenance models can be easily replicated and validated during the benchmarking exercises. Benchmarking for best maintenance practices should not be confined to energy sector as maintenance models with great attributes were found in the other sectors.
Authorship analysis by country and continent (8.2)	Chinese research output (40%) in these studies was the dominant. This highlights the importance of widening the research net for better learnings through SLR. France ranked second while Malaysia was third.	Future SLR must include other languages for the best maintenance practices. Chinese research done could not be studied and this could adversely affect progress of the dust and ash plant. Translation tools to be sourced so that more research work from the Chinese could be applied to enhance dust and ash plant performance. Chinese industry could be the best place for benchmarking as it represents 40% of the studies.
Scientific techniques that were applied in the studies (8.4)	Maintenance models that were studied in this review applied scientific techniques that included (Table 2 above): *advanced mathematics, advanced statistics, algorithms, neural network and artificial intelligence*. Application of AI will require large amounts of reliable annotated sensor data and well-trained machine-learning algorithms [14].	There is a need to leverage on scientific and technological developments so that plants could be safer, and uptime enhanced. Matlab was the most common software used to study plant maintenance problems hence a need to acquire the skills to use this tool was found to be essential.

Item	Study findings	Notes for power plant maintenance practitioners
	Maintenance strategy models (92%) were considered to have the potential of positive impact plant uptime by the authors. Figure 1 demonstrated the critical value of maintenance within the company. The techniques applied in these studies constituted reliability engineering principles combined with advanced data analytic methods. The following is a list of the probability distributions (Degradation or Failure and Repair) that were identified in the literature: • Normal distribution or Gauss distribution or Bell curve • Lognormal distribution • Beta distribution • Gamma distribution • Uniform distribution • Weibull distribution • Exponential distribution • Binomial distribution • Poisson distribution • Delta distribution, etc. These functions were central to the application of reliability engineering hence any study in this field will require the applicant to be competent in its use.	Company management has to invest in an effective and efficient maintenance strategy if the customer needs have to be continuously exceeded. Extensive application of these mathematical statistics techniques through computing power corroborated the concept of Nowlan and Heap [12] in 1978. Maintenance practitioners have to be competent in the mathematical statistics and maintenance fields (maintenance data analytics) so that insights and foresights can be used to unleash plants' potential. Minimum of about 33% of the articles in this sample were based on the artificial intelligence, this stressed the importance embracing technological development in the 21st century. Quality Data Management standard has to be developed and controls implemented so that its superior day-to-day decision-making can take place when these probability distribution functions are applied.
Type of publication used for maintenance models publication (8.5).	Articles that were reviewed were mostly published through journals (89%). This medium of publication ranked supreme as the quality of the research was subjected to rigorous reviews and their results were reliable.	Maintenance practitioners have to keep themselves abreast with engineering and scientific developments so that plant technical challenges could be tackled based on literature that was subjected to rigorous reviews for safer and plant with higher uptime. Academia-industry collaborations holds the key to unleashing of the industrial world class performance.

10 LIMITATIONS

This research was based on the publications between 2010-2023. It was carried out with English-speaking lenses and entered into the Google database, but it might have missed any other significant research that were published elsewhere (Eg: Chinese that were the leader in maintenance modelling research) or in languages other than English. Due to the multifariousness of the studies included in this review, meta-analysis could not be done as the objectives of the researchers were dissimilar. Examples of studies that were overlooked due to the nature of the inclusion criteria include those that were conducted in Venda, Afrikaans, Damara, Japanese, Chinese and Italian among other languages. The Google database originally gave 898 studies and systematic sampling methodology was applied, thereafter screening and filtering process yielded 45 studies. The characteristics of the 898 studies could have been compromised in the process of filtering and screen. Future research should therefore select sampling methodology that provides better characteristics of the main population and be aware of English-based and one index searches and aim to incorporate studies from regions previously thought to be underrepresented. Due to the possibility of author bias, these study flaws could be contributed to the replication issue [16].

11 CONCLUSION

Majority of the studies (44%) that were reviewed did not indicate the sector that their maintenance models were based upon while 66% of the studies had indicated the industrial sector basis of their maintenance models. This was found to be crucial if benchmarking was to be done.

Chinese academics (40%) were the leaders in this study in terms of output, followed by the French (7%). South African researchers (2%) were not active in this area, and this will make it difficult to benchmark locally as the best were in foreign countries. The remainder of the countries in the studies were on average of 2%. Future research must include translation tools so that more Chinese and other languages could be included in the studies.

Most of the articles (37%) had designed their maintenance models to be geared to preventive maintenance for safer and higher performing systems. Prescriptive (13%), Maintenance 4.0 (2%) and opportunistic maintenance (7%) strategies. Self-maintenance was identified as a new type of maintenance strategy. There is a need to leverage on the technological innovations (Eg: AI, etc.) so that maintenance of the plants can be enhanced, and safety improved. 21st century maintenance practitioner has to be literate in field maintenance data analytics. Maintenance data quality management was essential for a successful maintenance model. This will provide maintenance management with foresights and insights in the competitive world.

Maintenance models that were studied in this review applied advanced mathematics, advanced statistics, algorithms, neural network and artificial intelligence. Matlab was the most common software tool used to simulate the maintenance models. Maintenance strategy models (7%) were subjectively deemed to have no positive impact on plant uptime. Maintenance strategy models (35%) were considered to have the potential of positive impact plant uptime. Maintenance strategy models (57%) were classed to have positive impact on the plant uptime.

Maintenance models publications indicated an upward trend between 2010-2023 indicating the importance of maintenance in the business environment.

12 COMPETING INTERESTS

The authors declare that they did not have competing interests.

13 FUTURE STUDY

- Dust and ash plant maintenance model shall be developed in the future based on these learnings.
- Opportunistic maintenance strategy was found to be applicable to dust and ash plant but literature covering this topic was scarce. Maintenance opportunity in this instance was not weather driven like in the wind energy sector. This area must be thoroughly researched to cover the identified gap in the future.

14 ACKNOWLEDGMENTS

The Ph.D. candidate would like to thank the University of South Africa (Unisa) for funding this research.

ABSTRACT

"Lean" is commonly known as the practice of improving efficiency and effectiveness by the elimination of waste. In relation to recruitment, waste can be the excess time spent on sourcing, screening and interviewing candidates for a position. Traditionally, recruitment has been reactive and works on filling a vacancy only when the position opens. This approach is feasible for general workers but falls especially short when acquiring talent for higher positions. Talent acquisition is therefore a more strategic alternative to recruitment, where the recruiting team creates talent forecasts and actively searches for talent that will match the current and future needs of the company. This research aims to study strategic means of acquiring talent for organisations, while implementing lean principles within the traditional recruitment process. This method of employment will aid in talent matching while also reducing waste in the process.

Keywords: Recruit, Lean recruitment, Talent acquisition, Strategy

1 INTRODUCTION

With the fast-evolving world and people requirements, it is important for organisations to have the flexibility to progress and adapt to clients' needs. This means that organisations should strive to be well equipped for the speedily evolving customer, industry, environmental, social and economic needs in their respective endeavours. A crucial contribution to this is the workforce or human capital of an organisation [1]. Human capital refers to the productive capacity of people as income-generating actors in the economy. Human capital includes assets such as education, training, intelligence, skills, health and others that employers value, such as loyalty, integrity and punctuality [1,2]. Human capital is recognised as increasing productivity and therefore profitability [2]. It is the stock of skills and productive knowledge embodied in people. The concept recognises that not all jobs are created equal, but employers can improve the quality of their capital by investing in their employees [2]. Improving the rate of return, on human capital investment lies in enhancing the skills and earning power of individuals and increasing the efficiency of economic decision-making both within and outside the market economy. Therefore, the talent recruited should be well-skilled and equipped for the specific job and, more importantly, should fit into the future needs and vision of the organisation. For this to come to fruition, a more strategic and lean approach to recruitment should be followed.

Lean is a methodology that originated in Japan and which focuses on maximizing customer value while minimizing waste. Lean was introduced through the Toyota Production System (TPS) developed by Toyota in the mid-20th century. TPS was developed to improve the efficiency of the manufacturing process, reduce waste and improve quality [3]. It is based on the two main pillars: "just-in-time" (JIT) production and "jidoka" (autonomation) [4]. While JIT production focuses on producing the right amount of product at the right time, Jidoka has incorporated quality into the production process, allowing employees to stop production when defects are identified. Since its introduction, Lean principles have been applied to various industries outside of manufacturing– industries such as healthcare, finance, and software development [5]. The ultimate goal of Lean is to create a culture of continuous improvement. Therefore, all processes and activities are constantly evaluated, improved, "lean'ed" and modified to add value.

These principles of lean management can also be applied to the recruitment process to improve its efficiency and effectiveness, reduce waste and add value to both the organization and the candidates. According to Benuyenah [6] lean recruitment includes practices that avoid lengthy processes and requirements that add no value to the candidate's experience or employer's goals. The traditional recruitment process comprises the following steps: 1) Identify a vacancy, 2) Sourcing, (typically by advertising a vacancy for a position), 3) Receive and analyse applications, 4) Selection and finally, 5) Hiring. The problem is that these recruitment practices are lengthy, contain a redundancy of steps and duplication of information.

This paper aims to retrieve information on the implementation of a lean recruitment process in which candidates of varying positions are fairly and optimally recruited in a manner that will eliminate any wasteful activities for the hiring department as well as the candidates.

2 LITERATURE REVIEW

Recruitment is the process of identifying a vacancy, finding, evaluating, and hiring talent to fill and occupy an existing vacancy within the company [7]. The process of recruitment follows a specific process that is essential to running a business. The recruitment process is reactive and is initiated once a vacancy arises [7].

Talent acquisition is similar to recruitment as they both seek to obtain talent for companies, but they differ from one another in the sense that talent acquisition is a more strategic approach, and seeks to find long-term candidates for the company [8] as opposed to recruitment that looks at the current needs of the organisation. The goal of talent acquisition is to find candidates with the right skills, qualifications, and cultural fit for the organization to build a strong and high-performing workforce through human capital [8]. When conducting a search for talent, factors that must be considered by the talent acquisition specialists are employer branding, forecasting or future resource planning, diversification of the company's workforce and building a strong candidate relationship for the talent pipeline [9]. To identify long-term candidates the talent acquisition specialists need to have a clear understanding of the company's current status, as well as the possible future development expansion, so that the candidates hired for the position will remain relevant over the dynamic evolution of the company. To summarise, talent acquisition is a process that is continuous, proactive, strategic and forward-looking, unlike recruitment which is short-term and reactive.

A way in which the talent acquisition team may be more strategic in its approach to identifying and reaching the appropriate talent for positions within the company is by categorising and grouping positions in the company that have a similar level of availability in the labour market and allocating equivalent measures to attain the candidates. Candidates may either be a, 1) Simple hire, 2) Difficult mass hire, 3) Specialist hire or 4) Strategic hire [10].

2.1 Simple Hire

This is the case where the traditional recruitment process is most applicable. This group of hires are actively looking for employment and the supply is usually more than the organisation's demand. It is therefore the responsibility of the recruiting agent to select the right candidates from the pool of applicants. This category requires the posting of advertisements, (usually locally) as few skills and qualifications are required. This type of hire need not be too strategic, time consuming or costly [10].

2.2 Difficult Mass Hire

In this category it is ideal to develop talent communities for long-term retention of potentially suitable candidates [10]. Simple forms of active sourcing, for example targeted searches and addressing candidates on platforms such as LinkedIn, may be used to find these candidates. Structural measures to optimize the candidate experience include not only effective selection procedures, but also simple application methods and selection procedures that rely on speed, transparency and evaluation. The daunting task of covering large talent needs requires a comprehensive recruitment system in the sense of talent relationship management. It is not uncommon for carefully curated teams of HR personnel, and target department representatives, to address specific bottleneck departments moderated and managed by so-called talent relationship managers [10].

2.3 Specialist Hire

Specialist candidates are the individuals who are in exceptionally rare fields or have a unique skill. When these candidates are sought for the recruiting agent should merely focus on finding a candidate who can perform the task [10]. Specialist hires are especially challenging since members of this group of candidates are not usually actively looking for jobs. It is the responsibility of the recruitment department to search for, and headhunt such individuals, as applications might fall-short and not reach the candidate. When seeking to hire from this category the hiring department should clearly define the specifications for the position. Furthermore, for this type of talent, more time and resources will be spent 'hunting' for the talent. Once the talent has been identified the offer should be placed as soon as possible. Employee value preposition is key in the 'war for talent' in this category.

2.4 Strategic Hire

This type of hire addresses talent in senior management positions such as CEO's. Whereas all the above cases required a level of talent retention and building a talent community, strategic hire should be dealt with on a case-by-case basis. The organisation should be willing to spend resources and time in acquiring such talent as the search could extend nationally or even internationally. The employee value proposition plays a large role when offering a position to these candidates, but the organisation also seeks to benefit largely from such an employee [10]. Talent in this category should not only have managerial skills but should also have access to relevant markets that will contribute to the growth of the organisation.

2.5 Talent classification matrix

The figure below visually presents the four categories of the type of candidates identified in section 2.4. The horizontal axis represents the level of strategic relevance required by the recruiting department to acquire the talent, where the vertical axis indicates the availability of talent in the labour market for the respective categories. The sizes of the spheres are quantitative measures ranging from high (large spheres) to low (small spheres).

Figure 1 presents the four categories of the type of candidates found in the sections above visually. The horizontal axis represents the level of strategic relevance to the recruiting department to acquire the talent, where the vertical axis indicates the availability of talent in the market for the respective categories. The sizes of the spheres are quantitative measures ranging from high (large sphere) to low (smaller sphere) [10].

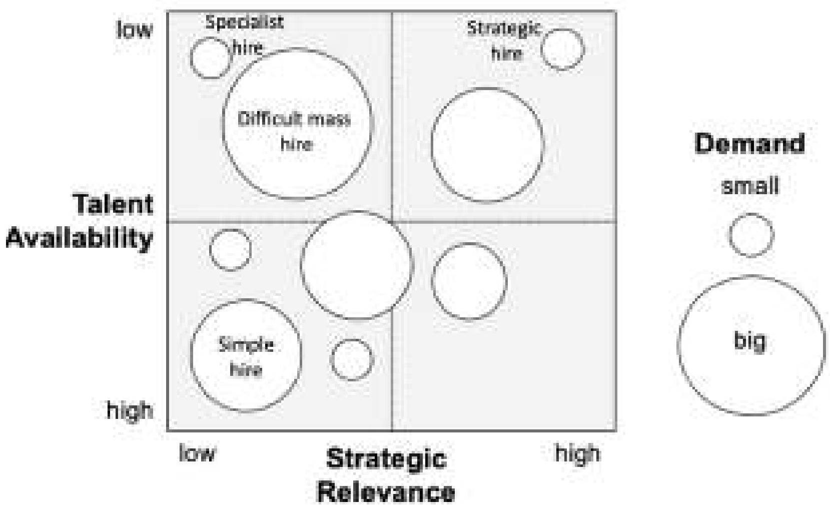

Figure 1: Talent classification matrix

2.6 Conclusion – Literature review

The literature mentioned above indicated that a more strategic approach to talent acquisition could be implemented in organisations, where talent would be categorised and grouped according to theory, availability in the talent market and the amount of effort required by the recruiting department to acquire the talent. The categories for the candidates include, 1) Simple hire, 2) Difficult mass hire, 3) Specialist hire and 4) Strategic hire.

3 RESEARCH DESIGN

A systematic literature review (SLR) was conducted to investigate different lean recruitment strategies in an attempt to modify and eliminate any identified waste in the traditional recruitment process. The research process was separated into three phases, namely, 1) Planning and reviewing, 2) Conducting the review and finally, 3) Documenting the review. The methodology, conducted by Yu Xiao and Maria Watson [11], was adapted as follows:

Planning the review

- Step 1: Develop a research purpose
- Step 2: Develop a research protocol

Conducting the review

- Step 3: Search for and access relevant literature
- Step 4: Selection of studies (based on relevant criteria)
- Step 5: Quality assessment for relevant studies
- Step 6: Data extraction
- Step 7: Analysis and synthesis of findings

Documenting the review

- Step 8: Reporting on findings

The steps above can be visually represented as sub-categories of the mentioned systematic literature review phase.

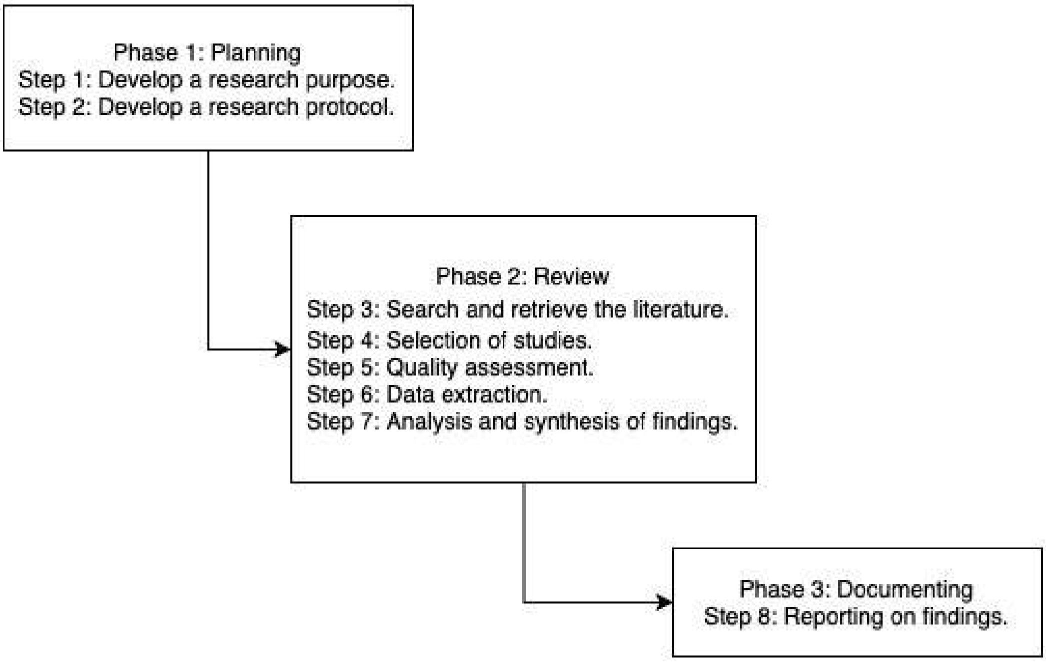

Figure 2: Systematic Literature Review Methodology [11]

3.1 Step 1: Research Purpose

The aim of the systematic literature review is to retrieve available literature on the implementation of lean principles within the traditional recruitment process, in an attempt to eliminate any wasteful steps, while adding value to both the clients (candidates) and the recruiting/HR department of the organization.

3.2 Step 2: Research Protocol

To retrieve the relevant literature, the purpose of the study should be precise and clearly defined. Keywords and inclusion criteria assist in acquiring literature that is specific to the desired study and the exclusion criteria eliminate any misconceptions that were not clearly defined from the keywords and inclusion criteria. The search protocol and the findings are presented in Tabel 1. The steps are presented in the sections which follow.

Table 1:Research protocol

Purpose of study	To investigate the implementation of lean principles in talent recruitment.
Keywords	"lean" AND "recruit" AND "talent acquisition" NOT "health" NOT "weight"
Search databases	• Emerald insight • IEEEXplore • Science direct • Scopus
Inclusion criteria	Literature providing insights into implementing lean practices in traditional recruitment. Literature on identifying wasteful practices within the recruiting departments of organisations.
Exclusion criteria	• Weight loss • Peoples' gifts and specialities
Quality assessment	• Use of language and writing credibility • Studies should be published in English • Repeatable and reputable scientific research methods should have been followed.

4 FINDINGS

The findings from the SLR are presented in this section.

4.1 Step 3: Search and retrieve the literature.

From a literature search of Science Direct, 10 articles were obtained from the keywords. The articles were not relevant to the study, as they did not incorporate lean principles in recruitment, but focused rather on talent management and retention. There were 140 articles retrieved from Emerald Insight-based on an evaluation of the articles' titles and abstracts. Many of the articles were related to the implementation of lean principles throughout the entire organisation but only 4 articles were relevant to recruitment. The IEEEXplorer search database produced 17 articles from the keywords used and one of them addressed the use of lean tools on the optimization of the professional insertion process of newly recruited engineers in a multinational company based in Morocco [12]. Out of a total of 167 articles obtained from the search using the relevant keywords only four of them met the inclusion criteria.

Table 2: Retrieved literature

Database	Retrieved Literature
Science Direct	10
Scopus	0
IEEEXplorer	17
Emerald Insight	140
Total	**167**

4.2 Step 4: Selection of studies based on relevance criteria

After reading the abstracts against the inclusion criteria only four studies were relevant. Several studies focused on talent management and general human resource management tools and strategies. On the other hand , the four retrieved studies provided strategies on acquiring talent as well as lean implementation within the recruitment process of organisations.

4.3 Step 5: Quality assessment for relevant studies

The quality of relevant literature was assessed and analysed by reading the full article or literature. The retrieved literature studies were assessed based on the information the studies provided on talent acquisition strategies and their implementation using lean principles. Quality assessment was based on the use of language, writing credibility and the reputable scientific research methods of the literature. It was concluded that all four retrieved studies were acceptable for inclusion in this chapter.

4.4 Step 6: Data extraction

The literature that was included in the study is summarised in Table 4. The table provides refence to the literature that was found relevant for the study, along with a summary of the content of each article.

Table 5: Summary of included literature

No.	Author	Title	Year	Summary	Reference	Source
1	Gavin W-Wright, William S-Jackson	Talent Rising; people analytics and technology driving talent acquisition strategy.	2018	How companies can leverage world-leading technology to build their own talent acquisition strategies.	[13]	Emerald
2	Pradeep Sashay	Lean Six Sigma tools in the hiring process	2015	How lean principles can be applied to achieve “best-in-class” recruiting capabilities, demonstrating the causal relationship between “value-added” recruiting activities and positive business outcomes.	[14]	Emerald
3	Eric Van Duren, Jim D’Amico and Kurt Knoth	Lean talent acquisition: one team’s journey of improvement	2015	How can lean performance improvement principles help transform an integrated healthcare system’s talent acquisition team to best in class.	[15]	Emerald
4	Vic Benuyenah	Can the concept of “lean management” be applied to academic recruitment?	2021	The implementation of lean processes helps to improve organisational practices; in the case of university recruitment,	[6]	Emerald

No.	Author	Title	Year	Summary	Reference	Source
				however, organisational processes have remained unchanged		

4.5 Step 7: Analysis and synthesis of findings

The key findings from the literature that have been summarised in Table 5 will be provided in this section.

4.5.1 Lean Philosophies in recruitment [6]

V, Benuyenah [6], used the five principles of Lean and weighed them against the recruitment process, which amplified areas of improvement within the recruitment process.

- **Specific value:** Render quality services for the candidate (time, logistics, efforts and communication)
- **Flow:** Creating a system that flows seamlessly without hindrances (bottlenecks) by eliminating unnecessary waiting times for the applicants and recruiter.
- **Pull:** Retrieve only the necessary and relevant information from the applicants and avoid redundancy of information
- **Value stream:** Simplify the process as much as possible and avoid redundancy of processes.
- **Perfection:** Give clear instructions to avoid confusion and 'back-and-forth' communication. Only involve the necessary parties for desired position.

4.5.2 Duplicates and redundancies

The nature of questions on the application form duplicates information already contained in the CV's [6].

4.5.3 Waste in recruitment

Lean recruitment may be achieved by identifying and getting rid of the non-value adding tasks within the recruitment process. The non-value adding activities were categorised into the standard 8 forms of waste was applied within the context of recruitment [14];

Transportation - Recurring communication between HR personnel, candidates, and line Managers. Having multiple phases within the recruitment process that required the candidates or personnel to regularly send information.

Inventory - Piling applications and CV's, due to broad job description.

Motion - Multiple people required to attend interview and sign-off documentation.

Waiting - Long waiting times for compiling short-lists or scheduling interviews. Waiting for sign-off of documentation by relevant parties. Waiting for background checks.

Overprocessing - An extensive review of all applications for compiling short-list

Overproduction - Having a large pool of short-list candidates that need to be interviewed.

Defects - Applications of candidates that do not meet the job requirements or do not qualify for the position.

Skills - Underutilizing current employees for referrals or not integrating them into the interview process according to their expertise.

4.5.4 Case Study

The case study referred to by Van Duren [15], is of a large health care organisation, Spectrum Health that had strong hiring needs since they sat with over 6000 position vacancies annually. Spectrum Health's talent acquisition department partnered with their lean process improvement team in an attempt to strategize their recruitment approach. The changes that came from their collaboration were structural, institutional, and cultural.

- **Structural:** The team realised that using the same recruitment structure for all kinds of hires was no longer appropriate. They developed a model with three swim-lanes that classified the talent as either high, moderate, or low level of intervention required by the talent acquisition team.
- **Cultural:** This is where the team had to introduce and promote the culture of continuous improvement and learning along with change management.

4.6 Conclusions - Findings

The literature highlighted the possible and present wasteful activities that take place in the recruitment departments and how this could lead to longer recruitment processes. These non-value adding tasks could cause frustration on the part of candidates, organisation departments waiting for positions to be filled and the recruiting department. However, the lean philosophies may be used to render services that are seamless and provide value to the candidates.

5 CONCEPT DESIGN FROM LITERATURE FINDINGS

The findings from the literature review and SLR in sections 2 and 3 are summarised in the form of the talent acquisition model presented in Figure 3. The model first categorised the types of hire [10, 15], and then considered tasks that would be most valuable for the candidates within each category.

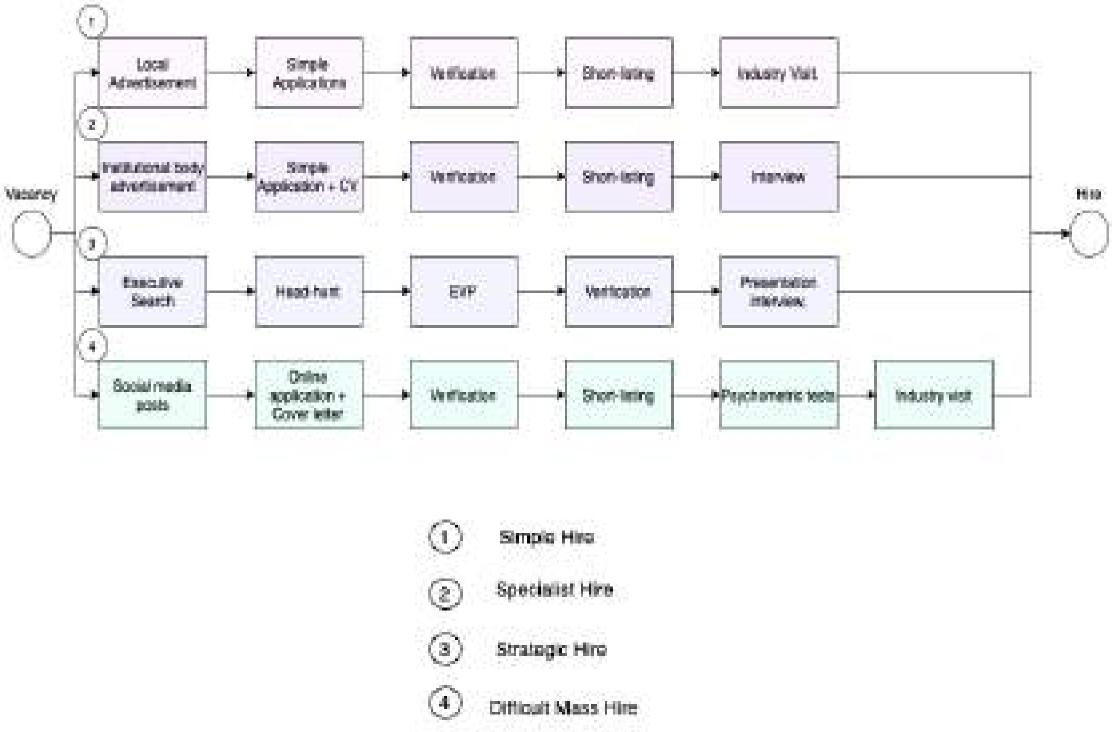

Figure 1: Talent acquisition process

5.1 Simple Hire

For the simple hire candidates, job posts and advertisements should be posted locally. The posts should not be fully digitized but rather advertised on posters near local communal areas such as shopping centres. The online applications should only request basic information from these employees, such as identification information (with proof and certified ID), contact details, and highest level of education. The simple hire candidates do not require to submit CV's as the positions that are listed under this category do not require high levels of education or experience. Candidates will be short-listed, strictly based on their highest level of education and locality, on a 'first-come, first-serve' basis. Finally, interviews are not the best way of verifying these candidates' fitness for the relevant positions, as some might struggle with articulating themselves, in a manner that fairly represents their abilities, due to language barriers or interview pressure. Industry visits with short-listed candidates, where they will be job shadowing for a few days before the final offer is made, would be a more fruitful approach. This differs from the traditional recruitment process which requires a lot of information that is not necessary for these types of candidates.

5.2 Specialist hire

The specialists hire candidates are low in availability in the labour market. As these candidates specialise in a specific domain within their industry they may be easily found within their industry's institutional bodies where they are registered. Vacancies may be advertised on these platforms. Advertisements should give a thorough description of the role and requirements needed for these positions. Online applications should be short and precise, with a focus on the attached CV, where the candidate's experience and expertise will be presented. As this will be a small pool of candidates, short-lists may be compiled faster and the interview panel should comprise the line manager of the department of the vacancy, seniors from the departments that will work closely with the candidate, and a representative from the HR department. This partnership approach will assist the recruiting department in reaching the specialists quicker since the advertisement will be directed to the specialists, as opposed to having a general online post, in the hope that the qualifying candidate is reached.

5.3 Strategic hire

The strategic hire vacancies should not be posted on social networks or locally, but an executive search should be conducted for these candidates. The candidates in this category are not seeking jobs and the talent acquisition team should actively headhunt these candidates from their current positions. The employee value proposition (EVP) plays a big role and attracting these candidates since these candidates are potentially in already existing positions in other organisations. The identified candidate should present his or her work, experience and contributions to a large panel consisting of line managers, employees from different levels, and external experts in the field. An offer should be made shortly after the presentation has taken place. The search for these candidates may be international.

5.4 Difficult mass hire

The difficult mass hire candidates are the candidates actively seeking work and take up a large number of positions in the organisation. These candidates may be reached by placing advertisements on social media platforms such as LinkedIn. The applications should retrieve most of the applicant's information for easier compilation of short-lists. The online applications should be divided into two stages, the first of which will retrieve the basic information of the candidates as well as an overview of their experience in relation to the job requirements. The short-list will be compiled from this first stage of the applications. The second stage will request more details on the candidates for further, and in-depth, evaluation of the candidates. Psychometric tests will evaluate the candidates fit within the organisation, problem-solving skills, and critical thinking abilities. An industry visit will serve to assess the candidates fit within the organisation through job-shadowing, after which an official offer may be placed. This differs from the traditional recruitment process since this approach understands that these candidates have little work experience, but they do have the qualifications for the position. In this case, the cover letter allows the applicants to justify why they are the perfect candidates for the position, as opposed to requesting a CV and short-listing based on experience and qualification alone.

6 CONCLUSION

With Lean being a common tool used by industrial engineers, this paper sheds light on how industrial engineering principles may be applied within the human resources departments. The talent acquisition model in Figure 3 was derived by puzzling together lean tools and strategic talent acquisition from literature. This will assist in targeting talent that is fit for the job through a seamless process that will not just reach the right potential candidates but will also save the HR department time and frustration in the process. Lean recruitment can also be achieved by understanding the different position rankings and categories; 1) Simple hiring, 2)

Difficult Mass hire, 3) Specialist Hire and 4) Strategic hiring within the organisation. Moreover, this will result in value-adding candidates in the organization. Failure to do so will result in organizations either struggling to find applicants that meet the requirements for the position, or on the other hand , will have to work through a long list of applicants and sit through many interviews unnecessarily. This talent acquisition model can assist organizations with their recruitment process, reducing the amount of man hours spent on recruitment. The model is scalable to the size of any organization. The customization and elimination of redundant steps makes this technique unique and will ensure that organizations get talent in an effective and efficient manner as they will be targeting active, passive and not-seeking candidates.

7 LIMITATIONS AND FUTURE STUDY

The talent acquisition model has been developed as a summary based on the principles found in literature on Lean recruitment. The model considered the four types of candidate hires that an organisations recruitment department should consider when attempting to fill a vacancy, and the correct approach to be used for each type. For more accurate results, future studies will not just focus on literature but should also be tested practically. In addition, future studies should focus on incorporating organisational cultural aspects of recruitment as well.

ABSTRACT

Tomato plants are uniquely sensitive to extreme weather variation. Consequently, their exposure to the wrong environment may result in deficient fruit growth, disease or pest infestation and ultimately significant yield loss. Farmers require improved farming techniques to consistently meet consumer demand in today's highly competitive agricultural market. Greenhouses have been employed to achieve a conditioned environment for optimal growth. In this era of digitalisation, the operation of greenhouses can be automated to improve operational excellence. The qualitative study outlined in this paper was conducted through a semi-structured interview administered to a South African greenhouse farmer to determine the optimal parameters for farming tomatoes. In addition, a literature study in the global and African context was undertaken to validate the interview findings. The research established the role of manual labour and ideal design parameters for tomato greenhouse farming. The determined parameters were employed to establish a digital framework for automated greenhouse farming.

1 INTRODUCTION

Tomato consumption in South Africa (SA), according to a study by the Agriculture, Forestry and Fisheries department, was recorded at over 400 000 tonnes for 2016 with a 4% increase from 2015. Furthermore, a growth of 29% in the South African global export value of tomatoes in 2016 is evidence of the international demand for tomato production and of the necessity for the development of greenhouse production methods [1]. A significant percentage of crop yield is lost annually due to humidity related diseases and random instances of extreme weather variation. Hence, farmers require improved farming techniques to strategically meet the consumer demand in today's highly competitive agricultural market [2]. Fortunately, open-source software and technologies such as moisture and temperature sensors have become widely available and affordable. These sensors in conjunction with microprocessors allow for valuable data collection and processing of greenhouse climate parameters. A Fourth Industrial Revolution (4IR) system-network of these devices can allow for off-site control of the greenhouse to achieve optimal growing conditions in real-time, increased productivity and efficient resource usage [3].

In this paper, the open-source 4IR technologies which facilitate effective monitoring and autonomous control of greenhouse conditions are identified. To facilitate this, firstly the optimal environmental parameters for tomato growing are determined. Secondly, the role of manual labour in the greenhouse farming of tomatoes is defined. The paper is structured as follows: Section 2 presents the literature review which focuses on the growth stages for tomatoes and the role of manual labour in the greenhouse farming of tomatoes. Thereafter, the research method is outlined in Section 3 before the results are presented in section 4. The discussion on the results obtained and the study recommendations are then outlined in sections 5 and 6 respectively.

2 LITERATURE REVIEW

2.1 Introduction

In South Africa, tomatoes are farmed across the entire nation, with the Limpopo province being the most successful with 3 590 Ha of tomato farms as a testament to its ideal-warm climate conditions. The Kwazulu-Natal province followed by the Eastern Cape are also home to large tomato farms. Tomatoes are primarily produced during frost-free climate or otherwise in greenhouse tunnels [1]. Furthermore, South Africa is classified as a 'Semi-arid' region, with the majority of rainfall occurring during summer. The nation sees an average rainfall of approximately 464 mm [4]. As such, these weather conditions are ideal for the survival of the tomato plant. The next section presents the stages of tomato plant growth.

2.2 Tomato plant growth stages

One of the most common tomato types in Southern Africa is the Bush tomato ([5], [6]). This type of tomato plant will produce fruit throughout the growing season which is ideal for commercial farming [7]. The growth stages of the Bush tomato plant according to the Tomato Production Guideline [8] are as follows. The first process is germination. This is the process by which an initial root emerges through the coating of the seed and thereafter progressively through the soil while the seed is buried (planted) in the soil. Optimal temperature and water are critical to the health of the growing root at this stage [9].The second stage is the vegetative growth stage. At this stage, the seed rapidly begins to develop ground roots. The stem that has emerged from the soil becomes thicker and starts to form small branches and leaves. Fertilizer is crucial to supplement the growth of the plant at this stage because the plant will consume significant amounts of Nitrogen and Amino acids that promote cellular development [10]. Thereafter, the third stage is the budding or fruit setting stage. Buds begin to form and petals spread open, during this time pollination will occur and this is best promoted by bees. The pollinated flowers then grow into green tomato fruit as multiple fruit clusters begin to set on the plant [11]. The final stage is red colouring. As the green tomato fruit grows, a gradual change of colour takes place until the fruit is in a shade of red. This is a sign of fruit ripening but is not an isolated indicator of ripeness. Furthermore, the red colouring process is considered the final stage of development before harvesting [11].

Table 1: The growth stages of the tomato plant

Growth Stage	Duration [days]	Accumulated Duration[days]
1. Germination	6 - 8	8
2. Vegetative Growth	14 - 16	24
3. Fruit Set	14 - 21	45
4. Red Colouring	14 - 16	61

Table 1 above specifies the sequence of growth stages and each associated duration. Germination is the shortest yet most critical stage of seed development. Traditional conventional farming methods have limitations and lack reliable efficiency levels to produce enough fruit. Furthermore, the effects that climate change has on agriculture makes traditional farming even more unreliable [12]. Due to the limitations of conventional farming methods, farmers are now exploring Controlled Environmental Agriculture (CEA) like the use of greenhouses. Greenhouse developments have afforded farmers the chance to produce crops at any given time of the year. Greenhouse farmers can therefore farm crops without the limitations and restrictions caused by undesirable climatic conditions and soil landforms. The following sections outline some crucial environmental conditions for growing tomatoes.

2.3 Optimal environmental conditions for growing tomatoes

2.3.1 Air temperature

For optimal tomato plant growth, it is important to note that air temperature corresponds closely with soil temperature. The following ideal air temperature ranges have been identified for each growth stage of the tomato plant according to [8]. From the data in Table 2, a minimum air temperature of 10 degrees Celsius serves as the lower boundary whilst a maximum of 34 degrees Celsius serves as the upper boundary. As shown in Table 2, ideal temperatures for tomato growth generally varies less during the vegetative growth, fruit setting and red colouring stages.

Table 2: Temperature ranges per development stage for optimum tomato production

Growth Stage	Temperature [°C]		
	Minimum	Optimum	Maximum
Germination	11	16 - 29	34
Vegetative Growth	18	21 - 24	32
Fruit Set – Day	18	19 - 24	30
Fruit Set – Night	10	14 - 17	20
Red Colouring	10	20 - 24	30

Furthermore, warm climate conditions that achieve suitable temperatures for tomato growth are ideally accompanied by sun-light/radiation [14].

2.3.2 Soil requirements

Soil composition is critical to the flourishing of the tomato farm, soil acidity in particular should ideally be maintained within a pH range of 5.5 to 6.8 [7]. A high soil acidity is linked to the harmful wilting of plants. Furthermore, fertilisation content for Bush (Determinate) tomato production should contain the following optimal quantities per growth stage:

Table 3: Nutrient requirements *of strong determinate tomatoes* [8]

Growth Stage	Mineral Nutrient					
	N	P	K	Ca	Mg	N:K
Pre-plant	50	50	65	0	0	1:3
Transplant to flowering	45	18	65	10	8	1.4
Flowering to fruiting	55	18	110	70	13	2
Harvesting	70	12	120	55	3	1.7
Total:	220	98	360	135	24	1.6

The values contained in Table 3 above are in units of Kg/ha, the minerals represented are Nitrogen (N), Phosphorus (P), Potassium (K), Calcium (Ca) and Magnesium (Mg). Potassium and Nitrogen are clearly the highest nutrient consumption of the tomato plant, playing a key role in both plant and fruit growth during flowering, fruiting and maturing of the fruit until the time of harvest.

2.3.3 Carbon dioxide levels

Carbon dioxide (CO_2) level in a greenhouse enclosure has been directly linked to crop yield [15]. An experiment was conducted over a period of 300 days by [16]. Results revealed an ideal CO_2 level of approximately 0, 10 % of total volume. It is important to note that CO_2 costs can be reduced by only dispersing CO_2 whilst there is solar radiation and the greenhouse windows are unactuated (closed) [16]. The ideal internal temperature for a tomato greenhouse is an average temperature of 25°C and the ideal CO_2 concentration is an average of 500 ppm which is approximately 0.05% of total volume [15].

2.3.4 Irrigation levels

Irrigation quantities can be represented as a percentage of evapotranspiration (ETc). Evapotranspiration refers to a measure of the evaporation from the soil surface combined with the transpiration of the actual plant. An experiment was conducted for optimum daily irrigation levels for the production of tomatoes, the following three irrigation levels were observed: 50%, 75% and 100% ETc. Each level corresponds to an amount of irrigation water. A 50% ETc is equivalent to 290.65 mm of irrigation water, likewise 75% ETc is 435.97 mm of irrigation water and 100% ETc is equivalent to 581.30 mm of irrigation water [17]. The results obtained indicate a significant relationship between irrigation and fertilization of the soil, hence it is important to maintain ideal soil composition in conjunction with irrigation control. Maximum plant height was achieved under a 75% ETc conditioning, as well as the highest number of healthy fruit and the highest number of total fruit yield [18]. In conclusion, an average irrigation level of 435.97 mm through a dispersion routine of twice a day as discussed above is identified as the optimal irrigation level for the production of tomatoes. However, the study further reveals that composition of the soil has a much greater influence on plant health and growth than irrigation [17].

2.4 The role of labour in greenhouse farming of tomatoes

The production of tomatoes remains a labour intensive process and this implies that a significant expense is attached to manual labour. The soil is initially prepared for plantation, as this involves the removal of unwanted weeds, raking and the laying of fertilizer. Seeds are then dispersed, either by hand or by mechanical device to assist a manual labourer. If seeds are initially planted in containers, they will need to be transplanted [18]. As a tomato plant grows and increases in size, the plant will require support in the form of caging or staking to promote vertical growth that will ultimately maximize fruit yield. Staking is done manually and is a time consuming process, however, the benefits of staking also include reduced risk to disease and a reduced space consumption per plant [7]. Furthermore, the pruning of stems and leaves is a task that is done manually and regularly. This task requires discretion as incorrect pruning techniques may be harmful to the plant [18]. Irrigation and ventilation systems may be manually controlled, in such case, irrigation pipelines and taps will require opening and closing. Similarly, ventilation fans or windows will need to be switched on and off or opened and closed [3]. The most manual labour intensive task, however, is the task of harvesting the fruit produce, similarly to pruning this task requires discretion and is done regularly as many clusters of fruit will begin to ripen at once [7].

2.5 Open-source 4IR technologies for greenhouse automation

It is important to note that greenhouse operations can vary from having minimal technological contribution to being largely autonomous [19]. 'Open-source' technology refers to the characteristic of a software and its associated devices that can be modified freely – by the user - to better suit the specific needs of the user. The programmable codes of such devices are often shared online and can be further developed with ease [20]. In an agricultural context, the device may be a microprocessor that is programmed to receive, process and communicate specific information to a network of actuators and sensors to control a greenhouse environment [3]. In addition to this, these networks can be made wireless and self-sustainable through the use of renewable-energy supply [21].

2.6 Types of greenhouse structures

Several types of greenhouse designs have been developed over time based on attempts to meet the various growth needs of different crops. The two major types of greenhouse structures are referred to as 'Free-standing' and 'Ridge-furrow'. Although the frame structure design may vary, the general materials used for the frame are aluminium, plastic, steel or wood [22]. Furthermore, the frames' truss structures must be strong and durable without being too large in dimension such that it obstructs a significant amount of light transmission into the greenhouse because this will affect the uniformity of crop growth [23]. The materials generally used for the transparent enclosure walls of greenhouse structures are glass, plastic or polyethylene, these are critically selected for their role in heating, insulation and security of crop from theft. Free standing greenhouse types include the arc type, even-span design, Gable-roof design, Uneven-span design, Quonset structure and Lean-to-Greenhouse structure ([22], [23]). On the other hand, Ridge-furrow structures (which are more economical) include types like the Saw-tooth design and the Venlo design [22]. Given these options, the key question remaining is which combination of technologies and materials are suitable for optimal tomato plant growth in an African context? The next section outlines the methodology used in the paper to answer the question.

3 RESEARCH METHODOLOGY

The study followed the qualitative research design, and this was done using a semi-structured interview and secondary research via observational note-taking of four online videos on tomato greenhouse farming as the research methodologies. The observational note-taking through desktop research was conducted as a means of overcoming the limitations posed by the COVID-19 pandemic and South African national lockdown restrictions which were in place when the study was conducted. An initial target population of five farmers with Tomato Greenhouses was set out. These were identified and selected based on their farming experience (at least five years' experience). However, only one farmer agreed to participate in the study. The subject participated in the primary research study by individually responding to the survey instrument via a telephonic interview rather than a face-to-face interaction in consideration of the risks associated with the COVID-19 virus at that time. A qualitative approach was selected because the study aimed to understand the optimal parameters for tomato greenhouse farming for the purposes of identifying optimal 4IR technologies. Qualitative studies make it easy to interpret phenomena and what those interpretations mean in each context. One of the advantages of qualitative research is that it gives access to detailed information about the research topic which is useful in answering how and why questions [24]. This will limit bias and make it easy for scientific generalisation to be made. Figure 1 below summarizes the steps followed in collecting and analysing data for the study.

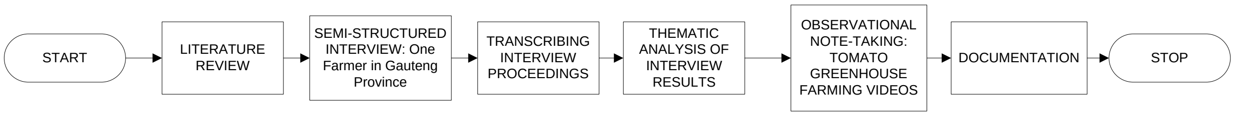

Figure 1: Steps in conducting the research study

Firstly, a systematic literature review was conducted to understand the topic in detail and to aid in developing interview questions that were relevant for the study. Secondly, semi-structured interviews were conducted with an identified farmer from the South African Gauteng Province. One of the disadvantages of semi-structured interviews are that they are time-consuming [25]. To overcome this challenge, the interview was timed to be no longer than forty-five minutes. Another disadvantage is that the information gathered during the interview may be difficult to analyse and generalise [25]. The research instrument used during the semi-structured interview was made up of a total of thirteen questions and four sections consisting of a mixture of dichotomous and open-ended short questions. The interview was intended to obtain a measure of ideal parameters for the optimal growth of a tomato plantation within a greenhouse; the role of manual labour within the operation of a tomato greenhouse facility was also intended to be defined. This was followed by the transcription of vital points that were deducted from the interviews. Lastly, using Nvivo software, the responses were grouped according to categories through the generation of themes and attribute codes. This made it easier to analyse the information. To validate the interview findings, observational note taking of four videos on tomato greenhouse farming available online was conducted. In addition to this, the optimal combination of applicable 4IR technology for an automated tomato greenhouse facility were then derived based on the semi-structured interview responses and four videos analysis.

4 RESULTS

The results section below have been separated into two parts based on the source that the information was obtained from. The results shown in section 4.1 are those obtained through the semi-structured interview (primary research).The results contained in section 4.2 have been extracted through the observation of four online video sources (secondary research). Unfortunately, the response rate to the research instrument was less than desired which may be a consequence of the COVID-19 pandemic. For this reason, four video observations derived from a global context containing information regarding greenhouse farming, which are publicly available online, were utilised to validate the results of the primary research and to better respond to the objectives of this study.

4.1 Semi-structured interview results

The following results have been obtained through an interview conducted by the researcher and a respondent (farmer) in the field of greenhouse tomato farming. The identity of the farmer was kept anonymous to abide by set ethical considerations. However, it can be said that the farmer participating had over ten years of farming experience at a greenhouse facility located in Pretoria – Gauteng, South Africa. Table 4 below outlines the farmers' responses to the semi-structured interview conducted. These results are further analysed and discussed in section 5.

Table 4: Semi-structured interview results

Question	Response
Section 1: Background	
1. Where this greenhouse facility is located [city, province, country]?	Soshanguve - Pretoria, Gauteng, South Africa
2. What is your role/position at this greenhouse facility?	Farmer
3. What is the approximate capacity/size of the green house facility?	Approximately 800 plants in the greenhouse facility
4. What is the approximate capacity/size of a greenhouse workforce?	Two workers per greenhouse
5. What is the approximate annual fruit/vegetable production rate of the greenhouse facility?	Uncertain
6. Which crop/plantation has been attempted to be grown in the greenhouse facility BUT failed?	None, I prepare well and make informed decisions.
Section 2: Environmental Parameters for Tomato Growth	
7. Are tomatoes grown in the greenhouse facility?	Yes
8. If Tomatoes are grown in the facility, what are the success factors of doing so, in your opinion?	Care and maintenance Good fertilization Pest control using chemical sprays
9. Which Environmental Parameters do you believe are most crucial to healthy tomato growth? Please list in order of significance and state ideal quantity range. [Example: Temperature, 23°C - 27°C].	Hot climate, tomatoes must be grown during summer. Fertilization Sufficient Irrigation [Uncertain of parameter values]
Section 3: The Role of Manual Labour	
10. Which greenhouse related tasks are done by manual labour, please list in the table below?	All greenhouse tasks are done manually.
11. Which of the above manual labour tasks do you believe can ideally be replaced by digital/mechanical automation?	Irrigation Spraying of pest control chemicals
Section 4: Greenhouse Automation & Digital Technologies	
12. Is this greenhouse facility automated?	No, no technology. We only use simple mechanical tools.
13. If yes, which greenhouse monitor/control/analyses tasks are automated?	None.

4.2 Video observation results

Table 4 below contains four sections that each outline key observations (from online desktop research) with specific reference to an identified video source. These observations intend to validate the findings of the primary research results in section 4.1 in responding to the research objectives of this study.

Table 5: Secondary research results

	Video source 1	Video source 2	Video source 3	Video source 4
1. Title of video and reference	Amazing Greenhouse Tomatoes Farming - Greenhouse Modern Agriculture Technology [26]	Young farmer making a fortune from Greenhouse tomato farming [27]	Tomatoes Farming: Greenhouse Commercial Nature - Agritech in Future'. [28]	Greenhouse tomato farming [29]
2. Location of Greenhouse	United States of America	Kenya	United States of America	Kenya
3. Greenhouse structure material	Large metal frame structure and enclosed with multiple layers of polyethylene curtain	Gabled-roof design constructed using a wooden frame and enclosed with polyethylene curtain	Ridge-furrow type of greenhouse structure. The frame structure of the greenhouse is metal and the enclosure is made of glass panels.	A wooden structure and a polyethylene curtain
4. Recommended optimal parameters	- *Optimal temperature*: 24°C during the day and 18 °C during the night. - Light intensity: 20 $mol.m^{-2}.d^{-1}$ for maximum productivity	- *Optimal temperature* interval during the day as 16°C to 30°C and 13°C to 18°C at night	- Not mentioned in the video	- The farmer recommends that soil is frequently tested and that the environment is frequently sterilized.
5. Level of farming operations automation	- *Manual operations:* Seedling growing, connection of stalks to the plant stem; transportation; pruning and harvesting. - *Automated operations:* use of hydroponic computerised irrigation and nutrient control system, air temperature sensors, humidity sensors, soil moisture sensors and light intensity sensors.	- *Manual operations:* fertilising, pest control is achieved by inter-planting spring onions in the tomato plantation, seedling growing, connection of stalks to the plant stem; pruning and harvesting. - *Automated operations*: air temperature sensors only.	- *Manual operations:* limited to pruning and harvesting of ripe fruit. - *Automated operations:* This greenhouse utilises a fully automated system of 4IR technology combined with a hydroponic setup and foam slab use. Humidity, temperature, light sensitivity, fertilizer composition and irrigation levels are all monitored and controlled by a single computer system	- *Manual operations*: All operations are done manually. Tomato seeds are sown in smaller containers or in open-field plantations and then transplanted after 18 to 21 days. A drip-line irrigation system is also used in this facility, irrigation is manually controlled and the soil moisture is manually monitored. Furthermore, this farm promotes minimal handling of the tomato fruit for the sake of higher quality produce. - *Automated operations*: None

4.3 Analysis and Discussion

The analysis undertaken in this section is based on the five sets of results contained in section 4.1 and 4.2. This includes the primary research results from the semi-structured interview and the desktop research results of the four video observations intended to validate the primary research. Attribute codes for the optimal greenhouse parameters were generated by Nvivo software.

4.3.1 Ideal parameters for optimal tomato growth

Temperature, light intensity and soil moisture and nutrients levels were identified as the optimal parameters for tomato growth. Firstly, the first three sets of results identify tomatoes as being a warm climate crop. The large greenhouse facility located in the USA of video source one recommends an optimal air temperature of 24˚C during the day and 18˚C at night. In support of this, according to the information from the farmer located in Kenya of video source two, the ideal air temperature range to be maintained within the greenhouse is confirmed as 16˚C to 30˚C during the day and 13˚C to 18˚C at night. These findings correlate with the work by [8], which reveals a more detailed list of ideal temperature ranges as illustrated in Table 2 for each growth stage. The greenhouse farms in both video source three and four do not explicitly state the air temperatures maintained within their facilities. Similarly, the farmer who responded to the semi-structured interview claims that tomatoes are grown during the warm conditions of the summer season of South Africa and that the greenhouse farm is not technologically equipped to monitor exact temperature parameters. Secondly, the farmer in video source one identified the optimal light intensity as 20 $mol.m^{-2}.d^{-1}$. This finding correlates with work by [14] who recommended a light intensity of approximately 100 000 Lux (equivalent to bright sunlight radiation) during the day (08:00 to 16:00) for optimal tomato plant growth. The remaining three video sources and the semi-structured interview respondent have all been unable to specify optimal light intensity. An ideal soil pH range of 5.5 to 6.8 has been revealed through the literature review of Section 2. Thirdly, according to video source one, combining irrigation and nutrient supply via a hydroponic system is the ideal method of irrigation. Video source three is in support of this concept and claims that the irrigation and nutrient content of this hydroponic system can ideally be monitored and controlled by a single computer system. Both farms in video source one and three are located in the USA and are equipped with sophisticated automation technologies. Furthermore, the drained nutrient solution can be recycled through this hydroponic system provided that the nutrient solution is frequently tested and recomposed. In contrast to this, the farmer respondent as well as the farmers in video source two and four, located in South Africa and Kenya respectively, each use soil-based plantations in conjunction with a drip-line irrigation system. This method of irrigation is manually controlled. Optimal irrigation is done twice a day, in the morning and in the evening but soil moisture must be monitored or tested beforehand to confirm moisture requirements according to video source three. Finally, frequent soil testing is also emphasized in the results of video source three for the sake of monitoring soil pH and nutrient composition which both have a significant effect on crop health and crop growth. The farmer explains that Fusarium wilt and Bacterial wilt are consequences of soil with high acidity content. In the comparison of solid soil fertilizer versus hydroponic nutrient solution, we see that solid fertilizer is at a disadvantage; firstly in terms of soil pH control, secondly in terms of effective dispersion composition and lastly in terms of recyclability as described by video source three.

4.3.2 Optimal combination of open-source 4IR technology: Requirements mapping

Based on the analysis in section 4.3.1, the following list of requirements must be satisfied by the final design and therefore all concepts to be generated must adhere to each of these points to be considered for final selection:

1. The 4IR technologies control system must process and respond to environmental conditions in 'real-time'.
2. The 4IR technologies control system must maintain the greenhouse air temperature within the range of 13°C to 18°C during the night (18:00 to 06:00) and within 18°C to 30°C during the day (06:00 – 18:00) for optimal tomato plant growth [8]. In the event that the air temperature exceeds the minimum boundary, an artificial heating system must be activated to manipulate the greenhouse air temperature back to optimal midrange i.e. midrange of 18°C to 30°C is 24°C. Similarly, in the event that the maximum boundary is exceeded, an artificial cooling system must be activated to manipulate the greenhouse air temperature back to optimal midrange.
3. The 4IR technologies control system must maintain a light intensity of approximately 100 000 Lux (equivalent to bright sunlight radiation) during the day (08:00 to 16:00) for optimal tomato plant growth [14]. In the event that the greenhouse light intensity exceeds the minimum boundary of 95 000 Lux, an artificial lighting control system must be activated to return greenhouse light intensity to the optimal value of 100 000 Lux. 4.1.1.4 The 4IR technologies control system must maintain a soil moisture level of 75% ETc or 435.97 mm for a 1 hour duration twice per day (07:00 to 08:00 and 16:00 to 17:00) for optimal tomato growth [17].
4. In the event that the soil moisture level exceeds the minimum boundary of 430 mm during either of the 1 hour periods, the irrigation system must be activated until the soil moisture level is returned to 75% ET_C.

Figure 2: System context diagram

Based on the derived requirements, sensors for air temperature, light intensity and soil moisture monitoring are required for tomato greenhouse farming as shown in Figure 2 above.

4.3.3 Optimal 4IR technology for tomato greenhouse farming

Table 6 below summarises the selected digital design components identified for tomato greenhouse farming.

Table 6: Bill of materials and some 4IR technology for tomato Greenhouse farming

Design component	Description	Image of component (if applicable)
Foundation	Concrete	 **Figure 3: Gable roof design greenhouse [30]**
Frame structure	Aluminium frame: Gable-roof design	
Covering material	Glass panels	
Carbon fertilizer systems		
Heating system	Central boiler with piping rails	
Cooling system	Evaporative cooling - mist dispersion	
Lighting system	Induction lighting	
Temperature sensor	MELEXIS Infrared thermometer – MLX90614 0.02°C accuracy, -40°C to 125°C, 3 to 16V DC	 **Figure 4: MELEXIS Infrared thermometer [31]**

Microcontroller	KEYESTUDIO Arduino Uno R3 develop module board + USB lead	

The gable-roof glasshouse design was conceptualised as the best housing design for the context. This particular structure is an even-span, free standing structure with the more sophisticated material selection and more advanced open-source 4IR electronic components as compared to other structures. The selected light intensity sensor for this context is a digital component rather than an analog one. The infrared temperature sensor provides significantly more precise readings than its competitors but at a significantly higher cost. Each of the above mentioned open-source 4IR technology sensors are compatible with an Arduino microcontroller and can be connected in a wired network to effectively test the functionality and response of a greenhouse model such as the gable-roof glass greenhouse model concept.

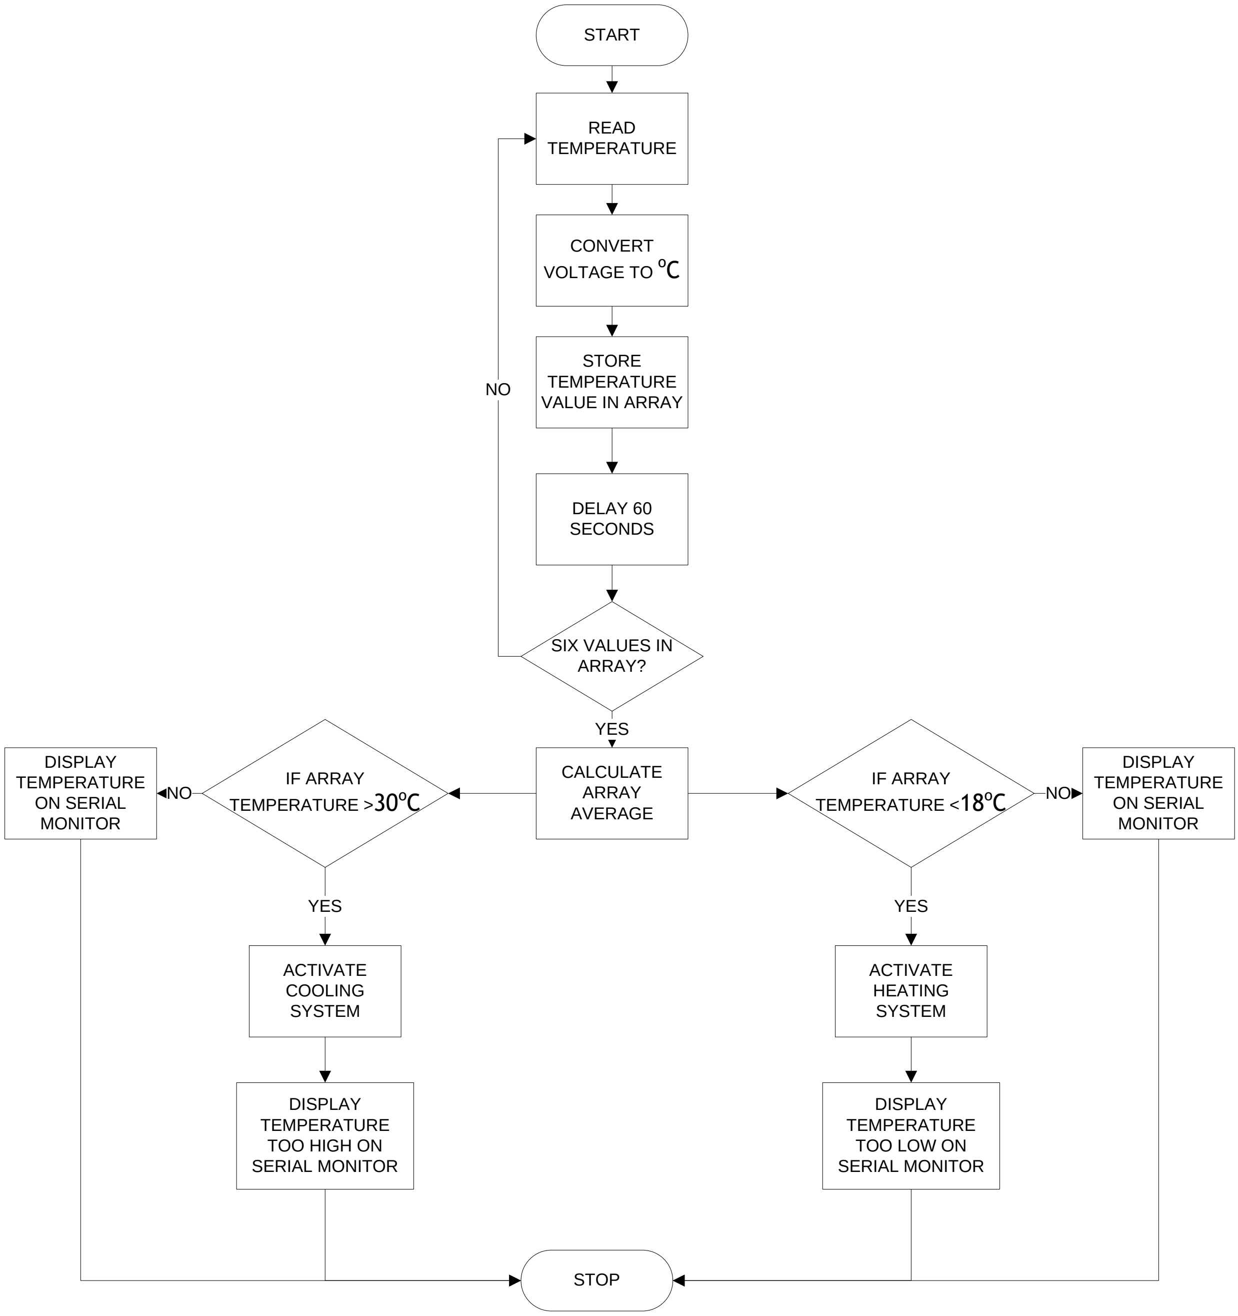

Figure 7: Programming logic for the temperature sensor

A sketch (programming code) was written for each sensor and uploaded into the Arduino microcontroller. The flow diagram in Figure 7 above represents the logical processing of the programmed temperature sensor circuit and its associated Arduino code is illustrated in Figure 8 below.

5 CONCLUSION

The qualitative study conducted identified optimal environmental parameters for tomato growth in a greenhouse facility. Air temperature, light intensity, irrigation levels, nutrient supply, soil pH and CO_2 levels within a greenhouse facility were identified as the most significant environmental parameters of a greenhouse tomato plantation. An understanding of the role of manual labour in operating a greenhouse facility was also determined. The significance of a farmers' discretion in manually performed tasks such as pruning and harvesting was acknowledged. In addition to this, the limitations of open-source 4IR technologies in performing tasks such as pest, virus and disease detection are revealed. It has been determined that manual labour not only influences greenhouse operational cost but also influences time efficiency and the quality of fruit produce. Furthermore, open-source 4IR technologies applicable to the optimal automation of a greenhouse facility have been identified. In response to the critical research question of this study, the following combination of open-source 4IR technologies will enable optimal automation and control of a tomato production greenhouse facility in a South African context: A greenhouse facility equipped with a hydroponic - foam slab system, air temperature sensors, humidity sensors, moisture sensors, light intensity sensors and CO_2 volume sensors. This network of sensors will provide input to a programmable microprocessor or computer system. The computer system will then process decisions based on sensor input data and activate control switches and actuators to manipulate; a boiler heating-humidity system fuelled by a sustainable energy source (preferably recycled wood), an array of UV-lighting bulbs, a recyclable nutrient-solution and irrigation system and lastly a CO_2 dispersion system. Finally, parameters such as soil pH and pest management will need to be carried out through the good agricultural practices identified in the analysis in Section 4.

6 RECOMMENDATIONS FOR FUTURE RESEARCH

In conducting this research study, the effectiveness of the research instrument and its associated response rate posed limitations on the success of obtaining significant insight into greenhouse farming of the target population of South African greenhouse farmers. In addition, the respondents' opinions and experiences may vary based on their individual expertise and career exposure thus affecting the findings. It is recommended that more focus be given to the target population in future research. Furthermore, it is recommended that research be conducted into the awareness and accessibility of open-source 4IR technologies amongst farmers in lesser economically developed regions such as the continent of Africa. Further work can be conducted to design a tomato greenhouse model facility that employs the open-source 4IR technology network using selected technologies described in section 4 above. This optimal combination of technologies should be simulated and evaluated on its effectiveness in achieving the associated ideal environmental parameters. Furthermore the crop yield, the quality of crop produce and the economical parameters of this facility should be evaluated.

ABSTRACT

The lean philosophy has long since moved from manufacturing plants to other operations such as insurance and healthcare. The agriculture industry is no different in terms of production processes, facilities, people, and challenges. However, agriculture provides a different set of challenges due to seasonal variability, bulk production, processing and problems in handling and storage. An opportunity exists to introduce the Lean concepts in more depth in agriculture given the magnitude of waste and losses in this industry. Therefore, the aim of this study is to conduct a rapid literature review in order to retrieve available research on Lean implementation in the agriculture industry to direct future research. The study identified one hundred and two studies highlighting the different applications of Lean-Agri. Given the increase in publication over the years, it is evident that research into Lean-Agri is increasing but more research is needed to further highlight its value and its range of applications.

Keywords: Lean, Agriculture, Rapid Literature review

* Corresponding Author

1 INTRODUCTION

Lean principles were originally developed in manufacturing as a set of tools and techniques that could eliminate waste from the production process. However, Lean techniques later moved from manufacturing plants to other operations, such as insurance, healthcare, government functions, non-profit businesses, and other economic activities, giving rise to Lean X concepts such as Lean accounting and Lean healthcare [1, 2].

The agriculture industry is no different from these industries in terms of production processes, supply chains, facilities and people. Also, its challenges are similar: less-than-desired throughput, facility layout that is not conducive to flow, a need for better project management and business engineering, the need for improved quality management and much-needed assistance with human resource planning and management.

The farmer is essentially a Jack of all trades and master of ALL, required to know various technical disciplines such as mechanics, hydraulics, electrical power, irrigation, structural design and, in recent years, electronics. Over and above these skills, farmers are required to understand how to run a profitable business, including the management of a workforce and resources. Additionally, farmers need an array of knowledge in the chemistry and the science of agriculture itself. They are expected to do all of this to provide for their families and produce for the country while facing unpredictable (natural) circumstances. In this sector, as in other sectors, global competition has resulted in a movement to large-scale production, greater use of standardised technology and more organisational and managerial innovations [2]. The management tools used in the agricultural sector are specialisation, formalisation and standardisation, all of which link to the trend towards fewer and larger farms [2].

Outside the farm, the Agricultural supply chains are complex systems that face the challenge of maintaining the freshness of agricultural products during staging, handling, packaging, and storage [3], while at the same time facing the challenges of integrating the agricultural supply chain into mainstream retail and distribution channels.

Fortunately, Lean is increasingly used in some parts of the agricultural sector [2]. However, differences exist in how Lean is used in the agricultural sector compared to how it is used in the manufacturing sector. It is not clear how Lean principles and tools adapt to farm operations or how farmers interpret Lean Thinking [2]. The challenge remains that Lean in agriculture provides a different set of challenges due to seasonal variability, bulk production, processing and problems in handling and storage [1]

An opportunity exists to introduce the Lean concepts in more depth in agriculture given the magnitude of waste and losses in this industry. However, before introducing Lean principles in more depth to a wider variety of agri-industries, it is important to understand in which of these agri-industries these principles have already been implemented. This will assist with a starting point to have the biggest impact.

The aim of this study is to conduct a rapid literature review, to identify available research on where Lean implementation has occurred in the agriculture industry. Future research can then focus on a further in-depth literature review to determine the details of each of the implementation processes.

The rapid review method that was followed is described in Section 2. The findings are presented in Section 3. Proof of validity is provided in Section 4, after which the conclusion and future research are presented in Sections 5 and 6, respectively.

2 METHOD

The rapid literature review process was used as guidance for this initial study before a more systematic review is conducted in future [4]. The methodology was selected for the rapid search and appraisal of existing research on Lean applications in the agriculture industry. By using elements of a full systematic review, a rapid review provides a rigorous method for assessing existing literature while reducing the overall scope of the review process by allowing concessions such as focusing on the research question, limiting search strategies and/or performing less sophisticated analysis [5].

This study utilised a rapid review strategy using the SALSA framework [5]:

1. Search - A systematic search of databases;
2. Appraise - Selection of relevant studies using inclusion and exclusion criteria and grouping by agri-industry;
3. Synthesis - Extraction of relevant data from literature sources; and
4. Analyse - An analysis of the literature found.

2.1 Search – Systematic search of electronic databases

The aim of the literature review was to investigate whether Lean principles are applied in the agricultural industry. The search was limited to journal articles, conference proceedings, books and book chapters and literature written in English. Since this was a rapid review, only one electronic database (Scopus) was searched using keyword search strings with Boolean logic. When publishing research related to Lean principles, different terminologies (Lean manufacturing, Lean philosophy, Lean Management, Lean production) are used, as Lean is polyonymous. In a similar vein, different terminologies are used in agriculture. Instead of running the risk of unintentionally excluding valuable literature, five different search strings were used. These search strings, as well as the numbers of studies retrieved from each search, are presented in the search protocol in

.

2.2 Appraise - Selection of relevant studies

Inclusion and exclusion criteria were developed to remove irrelevant articles from further analysis (Table 1). Studies that focussed on Lean implementation in agriculture were included while studies that referred to biological sciences, weight loss, Lean Six Sigma, lean meat, lean agricultural season, lean agricultural yield or lean agricultural periods were excluded.

2.3 Synthesis – Extraction of relevant data

The relevant data was extracted from the selected studies. The list of selected literature is presented in the appendix, categorised by agriculture industry.

2.4 Analyse – Analysis of literature found

The literature sources that were extracted were analysed in terms of 1) the type of agriculture industry in which the Lean principles were implemented, 2) the names of authors and 3) the date of publication. It was also noted if the study was based on the larger agri-supply chain or at the point of production, namely on farms. The findings are discussed in Section 3.

3 FINDINGS

Findings from the five different search strings (indicated in Table 1), combined with the inclusion and exclusion criteria, resulted in an initial 119 studies. These studies were combined and duplicate studies were removed, after which 102 studies remained.

3.1 Lean Management in Agriculture

Different, but complementary, results were found in the five different search strings, as explained in the following sections.

Table 1: Search protocol

Objective of study	To investigate whether Lean principles are applied in the agricultural industry.				
Search strategy	The search was limited to: • Journal articles, conference proceedings, books and book chapters, • Literature written in English.				
Databases	Scopus				
Inclusion criteria	Research regarding Lean implementations in agricultural industries				
Exclusion criteria	Biological Sciences Weight loss Lean Six Sigma studies Reference to “Lean” meat in the context of farming Reference to "lean agricultural season", "lean agricultural yield" or "lean agricultural periods"				
Quality assessment criteria	Repeatable and reputable scientific research methods should have been followed.				
Keywords	1	2	3	4	5
	"Lean agri*"	Lean AND agri	Lean philosophy OR Lean manufacturing OR Lean principles OR Lean implementation OR Lean production OR Lean management AND agriculture	Lean philosophy OR Lean manufacturing OR Lean principles OR Lean implementation OR Lean production Within the subject area: “Agricultural and Biological Sciences”	“Lean farm”
Results found	13	40	60	94	2
Inclusion and exclusion criteria applied	6	30	39	42	2
Duplicates removed	102				

3.1.1 Research protocol 1 - Lean Agri

When the phrase “Lean Agri*" was searched on Scopus, 13 results were found. Papers with the phrases "lean agricultural season", "lean agricultural yield" or "lean agricultural periods" were excluded since this referred to specific deficits in seasons (dry spells), profits and periods. After considering this, only six papers [1, 3, 6-9] remained that truly referred to the application of Lean principles in the agricultural industry.

3.1.2 Research protocol 2 – Lean AND agri

After search protocol 2 (Lean AND agri) was followed, 40 results were found. However, seven results were not agri-related since they referred to management practices or lean drilling techniques or lean seasons. Another 4 studies were removed since they referred to lean meat. The remaining 30 studies were considered further and are presented in the appendix.

3.1.3 Research protocol 3 – Lean XX AND agriculture

After searching, 60 studies were found. Of these results, 19 were not related to the study since they referred to electricity, government, agri machines/implements, and the automotive industry. One study was excluded since it referred to plant genetics and another study was excluded since Lean was only mentioned in future research. Overall, the remaining 39 studies met the inclusion criteria and are captured in the appendix.

3.1.4 Research protocol 4 – Lean in agri

After following the search protocol, 94 conference proceedings, journal articles and books/book chapters were found. Of these findings, 33 were not agri-related, since they referred to other industries such as healthcare, construction, aeronautical, marine, software development, research facility, green engineering, automotive, restaurants, and agile manufacturing. Another 6 studies were excluded since they referred to Six Sigma in combination with Lean. One study was excluded since it referred to human weight loss and six studies were excluded that referred to animal/plant genetics to grow lean plants or lean meats. Three studies were excluded because Lean was not the focus of the study, it was only part of a bigger study. Another three studies were excluded since Lean was only referred to in future research. Ultimately, 42 studies remained.

3.1.5 Research protocol 5 – Lean farm

The search protocol delivered two papers, which were both relevant to the study and are therefore presented in the appendix.

3.2 Lean applied to different agri-industries

Of the 102 studies, four studies focussed on Lean management in agriculture. Of the remaining 98 agricultural studies that incorporated Lean principles, the majority came from the food and beverage industry (41 studies) and the timber industry (14 studies), as indicated in Table 2 and Figure 1. The detailed citations per industry are presented in the appendix.

After the food and beverage industry and the timber industry, the next highest numbers were from the crops industry and mixed farms (8 studies each), the red meat industry (5 studies), textile, dairy and fruit industry (4 studies each) and the fertilizer industry (3 studies). Single Lean studies were found in the poultry, coffee, floriculture, horticulture, pesticides, vertical farming and equestrian industries. These have been grouped as “other”.

Table 2: Number of research studies per agri-industry

Agri industry	Nr of research studies
Food and Beverages	41
Timber	14
Crops	8
Mixed farms	8
Red meat	5
Textile	4

Agri industry	Nr of research studies
Dairy	4
Fruit	4
Fertiliser	3
Other	7
Total:	98

It is evident that Lean principles are being applied to a variety of agricultural industries. However, in the overall context of lean implementation, these are not a lot of studies.

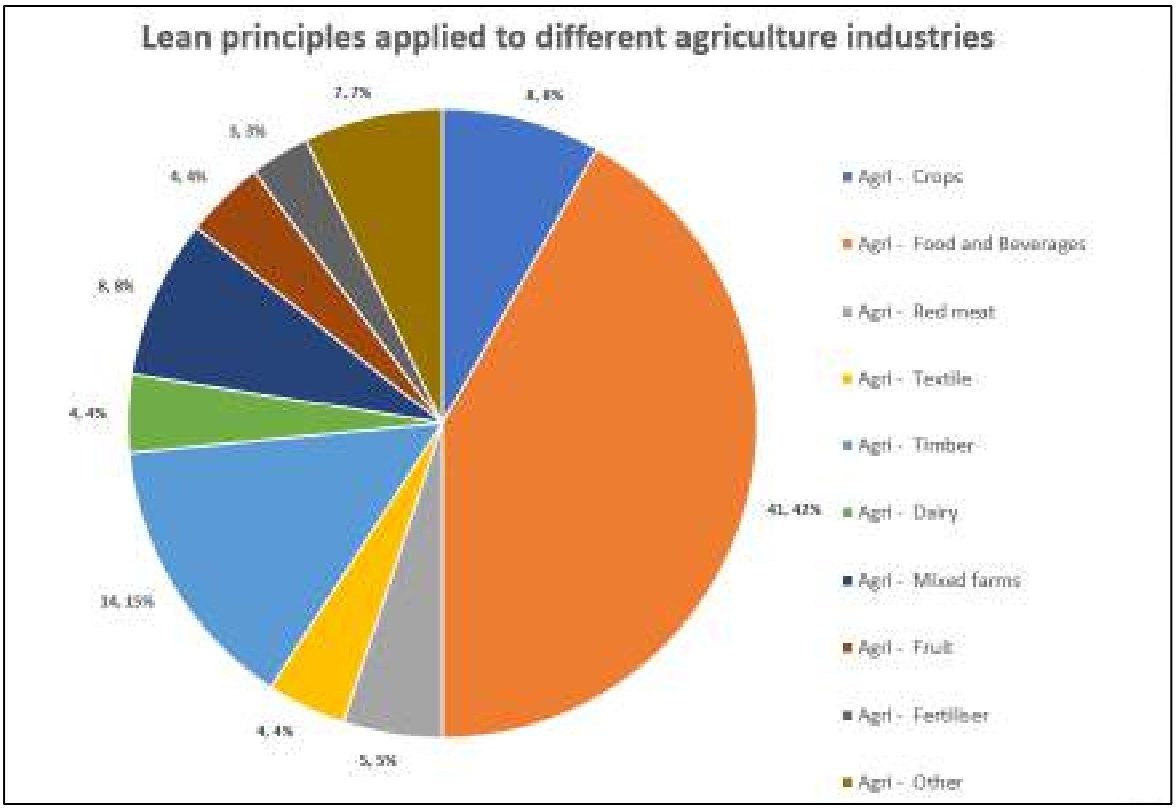

Figure 1: Lean principles applied to different agricultural industries

3.3 Authors

It emerged that there are a few prominent authors writing on the topic of Lean research in agriculture. Table 3 indicates the breakdown of the number of studies per first author, for the authors that published more than one study on the topic (as first author).

Table 3: Number of studies (if more than one) per first author

Authors	Nr of studies (As first author)
Caicedo Solano, N. E.	4
Melin, M. and H. Barth	3
Chen, H.	2
Dora, M.	2
Muñoz-Villamizar, A.	2
Pearce, D.	2

Authors	Nr of studies (As first author)
Taylor, D. H.	2
Zokaei, K.	2

Caicedo Solano, N. E. has four studies published [10-13] on using Lean principles for developing an operational model for minimising cost in agricultural systems. Sowing, cropping, and harvesting are usually treated independently. Waste and the sustainability of operations are generally not integrated into operational planning methodologies for agricultural production bBut Caicedo Solano [11] points out the need to have a clear and precise methodology to minimize waste in agricultural production systems to ensure sustainability. In this study, Lean manufacturing principles are used to identify agricultural operations and the variables that represent waste, build mathematical models, define constraints and illustrate the cost of waste, as well as its minimization through an objective function. In his 2022 study [10], he presents a mixed integer nonlinear programming problem model to solve the planning of agricultural production systems in the stages of sowing, crop maintenance and harvesting.

Melin, M. published two Lean studies done in Sweden. The purpose of the first study [2] was to develop a framework for Lean implementation in the agricultural sector, from an operational and strategic perspective. The study was conducted with a group of Swedish farmers. The aim of the second study [14] was to increase the understanding of Lean implementation in which value stream mapping (VSM) is used to create an action plan at a small dairy and cattle farm in southwest Sweden. Melin [15] also published a third paper (as the second author) to propose a Lean Implementation Framework that small and mid-size farms can use to increase production and profit and yet support environmental sustainability.

Chen, H., ***et al*****.** published 2 studies [16, 17] on Lean supply chains in the agri-food industry. The first paper aimed to support food supply chain decisions to achieve lean performance (that is to reduce/eliminate non-value-adding activities, or "waste" in Lean terms) [16]. The second study aimed to explore an approach to integrating knowledge mobilisation within agri-food supply chains to enhance the collaboration of all value chain actors and achieve a holistic reduction of waste [17].

Muñoz-Villamizar, A. also focussed on the agri-food industry in three studies [18-20]. The first study [19] analysed the gaps and trends, and suggested approaches and methodologies that should be addressed by future studies for implementing Lean and Green management in the agri-food sector. According to Muñoz-Villamizar[18], environmental efficiency should not be treated independently of production efficiency. Therefore, the second study integrated existing methodologies and approaches from Lean thinking, Industry 4.0 and mathematical optimization, and presented a toolkit for integrating, measuring, controlling and improving production and environmental performance in companies. The third study [20] presented a multi-case study in the agri-food industry in which water consumption in company activities is monitored, allowing them to improve their industrial processes based on Lean and Green practices, leading to a zero-waste strategy for this critical resource.

Pearce, D. has been involved in 4 studies in different countries to apply Lean principles in the food industry [21], horticulture [8, 22] and the dairy industry [23]. For the food industry, a systematic review (of 24 studies) was used to show the potential of Value Stream Mapping (VSM), not only to identify and reduce food losses and wastes but also to establish links with nutrient retention in supply chains. The horticulture study [22] determined the factors that drive sustainable performance through the application of Lean methods in the primary production segment of the supply chain for apples and pears. The South African study on horticulture [8] investigated the relationship between patterns of Lean practice implementation, farm size and sustainable performance among fruit horticultural primary producers in South Africa. Lastly, the dairy value chain was investigated in Uganda and used

Value Stream Mapping (VSM) analysis to identify hotspots and analyse the magnitude of both food and nutritional losses in the food value chain.

In 2014, **Dora** [24] stated that a very limited number of studies have focused on the implementation of Lean manufacturing practices within small and medium-sized enterprises (SMEs) operating in the food sector. The study then analysed the status of Lean manufacturing practices and their benefits and barriers among European food processing SMEs. Dora warned that Lean in agriculture provides a different set of challenges due to seasonal variability, bulk production, processing and problems in handling and storage. The study identified and categorised Lean waste and created a Lean implementation readiness index based on the operations management literature. Dora was also a co-author with Pearce, D. on the two horticulture studies [8, 22] as well as the systematic review of the food industry [21] and the value chain study of the dairy industry [25]. Preceding the dairy study of 2019 [23]. Dora also took part in the 2018 study [25] during which a survey was conducted among 246 supply chain actors about their general understanding of nutrition-sensitive agriculture while linking it with food and nutrient loss or waste reduction strategies.

Taylor, D.H. published two studies on applying lean in the agri-food industry. The first study [26] develop an innovative methodology to apply Lean value chain improvement techniques to a complete supply chain for a food product from farm to consumer. The second study [9] showed how value chain analysis techniques have highlighted opportunities for strategic change in a UK agri-food supply chain and presented an initial model of an integrated supply chain based on the application of lean principles.

Zokaei, K. investigated Lean implementation in the red meat industry[27, 28] and the agri-food industry [29]. The first red-meat study [27] highlighted the benefits of Lean production in one specific manufacturing area, the “cutting room”, where meat is split down from a carcass into retail cuts of meat. The second red meat study [28] continued to highlight the benefits of Lean production techniques in different stages of the red meat value chain and reported 2- 3% potential cost savings at each stage of the chain. The agri-food reference by Zokaei [29] is a book chapter in Delivering Performance in Food Supply Chains. The chapter reports on the findings from a major research project (33 extended supply chains) into the UK agri-food industry over a period of four years and across four primary food sectors (cereals, red meat, horticulture and dairy).

3.4 Lean farms

From the above search results, Lean Agri is applied mostly in production/manufacturing type environments like the food and beverage industry and the timber industry.

Agri-industries that are more farm-based are on the lower half of the results, such as crop production, mixed farms, the red meat industry, dairy and fruit industries.

Already in 2015 Dora [1] pointed out that there had been little literature and understanding of Lean in the context of agriculture and specifically farming. It appears that this was the first study that pointed towards lean farming (as opposed to Lean Agri in general).

During the literature search, only six studies [30], [1], [7], [15], [31], [32] referred to implementing Lean specifically on farms (not agri-processing industries). And when searching the term “Lean farm”, only two studies were found [30] [33].

3.5 Publication years

Without limiting the search to any period, the search results are spread between 2004 and 2023 (Figure 2). Since 2004 there has been a steady increase in the number of publications, with the highest number of publications (18) being in 2020. The publications of 2021 focussed on food and beverage (3 studies), mixed farming (3 studies), lean agri management (2 studies), timber (1 study), crops (2 studies), textile (1 study), dairy (1 study), fertilizer (1 study), fruit (1 study) and three “other” studies.

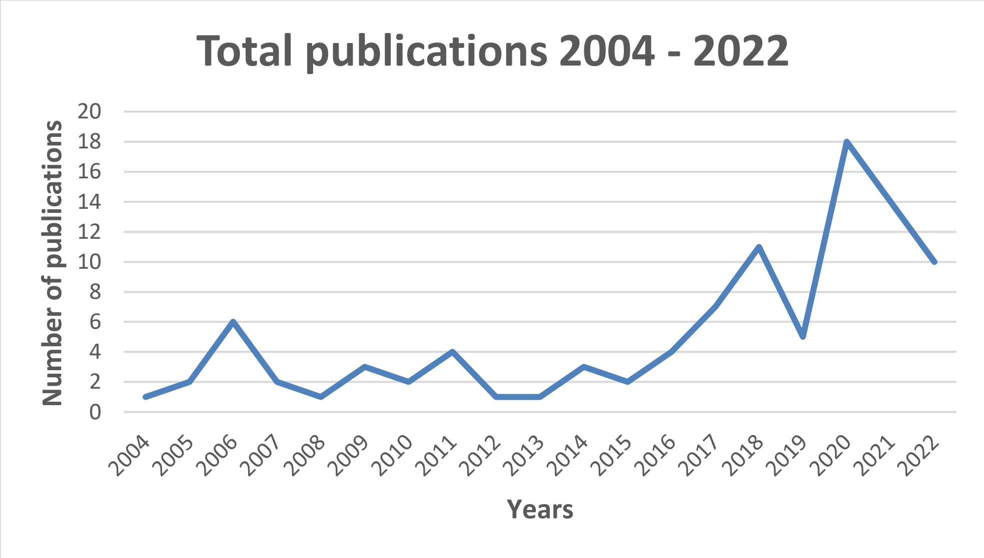

Figure 2: Total publications for the search period

The industries that have more than one citation per year are highlighted in Table 5. There seems to have been an increase in publications over the years, specifically in the food and beverage industry, crops, timber and mixed farming.

3.6 Title of studies

Given the titles of each of the 102 studies (presented in the appendix), a word cloud (Figure 3) of the 100 most used words was generated to illustrate the most pronounced themes of ideas captured by authors.

From Figure 3 the most used words (except for “lean”) are: value, agri-food, food, management, supply, development, production and sustainable. This is indicative of the change and focus that Lean agriculture offers the community by adding value. Support is provided to management and supply chains to increase production. Moreover, lesser-used phrases like "reduction”, “modelling”, “improving”, “integrating”, “adoption”, “strategy” and “design" also indicate the offering of lean-focused principles in agriculture by highlighting the benefits.

Table 4: Search results per agri-industry per year

	Crops	Food and Beverages	Red meat	Textile	Timber	Dairy	Mixed farms	Fruit	Fertiliser	Other	Total
2004					1						**1**
2005		1	1								**2**
2006		1	2		2					1	**6**
2007	1		1								**2**
2008					1						**1**
2009		1			1				1		**3**
2010		1			1						**2**
2011		2			1	1					**4**
2012		1									**1**

	Crops	Food and Beverages	Red meat	Textile	Timber	Dairy	Mixed farms	Fruit	Fertiliser	Other	Total
2013		1									**1**
2014		2							1		**3**
2015							1				**2**
2016		1		1	1		1				**4**
2017		6				1					**7**
2018		1		1	2	1	2			3	**11**
2019	1	4									**5**
2020	2	3		1	1	1	3	1	1	3	**18**
2021	1	7	1	1	2			2			**14**

Total	**8**	**41**	**5**	**4**	**14**	**4**	**8**	**4**	**3**	**7**	**102**

3.7 Keywords of studies

When looking at the details of the 102 studies, it was clear that there was a trend in the keywords used by authors. Thus, an analysis was conducted on the total number of occurrences of each keyword of the studies. Figure 4 depicts a clustered bar graph indicating the total count of keywords.

As indicated in Figure 4, the most common keywords (except for "lean") are "food", "manufacturing", "production", "supply chain", and "sustainability". This corresponds to the earlier discussions which identified the focus of the majority of the studies. It is evident that the studies emphasise the improvements and integrations that the lean philosophy has to offer the agricultural industry.

Figure 3: Word Cloud of literature titles

4 VALIDATION

To ensure that the rapid literature review is valuable to users, a transparent complete, and accurate account of why the review was done, what was done, and what was found, was presented in the study [34].

Furthermore, an adapted version of the PRISMA checklist [34] is used for validating the review conducted in this study (

Table 5). As can be seen from the checklist in

Table 5, this study adequately addressed the data gathering and data analysis phases of the research and the results and discussion of the various aspects of the study were adequately presented.

Table 5: PRISMA checklist for validation

Section and Topic	Checklist item	Section where the item is reported
INTRODUCTION		
Rationale	Describe the rationale for the review in the context of existing knowledge.	1.
Objectives	Provide an explicit statement of the objective(s) or question(s) the review addresses.	2.1.
METHODS		
Eligibility criteria	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	2.1.
Information sources	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	3.
Search strategy	Present the full search strategies for all databases including any filters and limits used.	2.1.
Data collection and selection process	Specify the methods used to decide whether a study met the inclusion criteria of the review.	2.1
Synthesis methods	Describe the processes used to decide which studies were eligible for synthesis.	2.1.
RESULTS		
Study selection	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	2.1.
Study characteristics	Cite each included study and present its characteristics.	Appendix
Results of syntheses	Present the results of all investigations of possible causes of heterogeneity among study results.	3
DISCUSSION		
Discussion	Provide a general interpretation of the results in the context of other evidence.	3
	Discuss any limitations of the evidence included in the review.	6
	Discuss any limitations of the review processes used.	6
	Discuss the implications of the results for practice and future research.	6
OTHER INFORMATION		
Support	Describe sources of financial or non-financial support for the review, and the role of the funders or sponsors in the review.	NA

5 CONCLUSION

This study utilised a rapid review for unearthing 102 different Lean Agri puzzle pieces across different agricultural industries. For example the food and beverage industry, timber, crops, mixed farms, red meat, textile, dairy, fruit, poultry, coffee, floriculture, horticulture, pesticides, vertical farming and equestrian were identified). Solving the puzzle highlighted the different possibilities of lean applications within agricultural industries.

This study found that many authors are well-known for publishing in the lean-agri space. It will be interesting to see how these researchers further develop the discipline in the future.

It was also found that most studies made use of "food", "manufacturing", "production", "supply chain" and "sustainability". This is evident in the improvements and integrations that the Lean philosophy has to offer the agricultural industry.

A few studies were found on the topic of lean management, indicating future (and needed) research in this area, as opposed to just the technical application of Lean in agri.

It was also found that Lean Agri is applied primarily in production/manufacturing type environments, like the food and beverage industry and the timber industry, and less on farm-based operations. It seems that little research has been done on understanding lean farming (as opposed to Lean Agri in general).

Given the upward trend and increase in publication over the years, it is evident that Lean-Agri is ascendant but more research is needed to further highlight its value and range of applications.

6 LIMITATIONS AND FUTURE RESEARCH

A rapid literature review allows for the review of a large body of literature. However, it may include limitations due to shortened timeframes, such as a lack of depth of analysis in the findings of each article, challenges in repeatability of the study and the potential for bias in interpretation of results [4].

Future research should now continue with a thorough systematic literature review to investigate the details of each study, as well as retrieve any studies that were missed.

While this study provided a full presentation of the current research of 102 studies, it did not focus on the detail of each of the studies. Future research should investigate the specific lean principles that were applied in each study. This will provide further guidance on the required research into Lean Agri.

This study has pointed out the application of lean in different agri-industries. It is suggested that future research focus on the in-depth analysis and investigation of each of the industry applications of Lean-Agri to determine the focus of further research.

It is commonly understood that Lean philosophy is quite popular in many spaces as there are numerous search results on academic databases yet, only 102 studies were found in the Lean agriculture space. It is worthwhile investigating why lean implementation is lagging behind in this application field.

The highest search results were found in the food and beverage industry and the timber industry, both of which are very "production-like" industries. Future research should focus on the application of Lean principles in non-production farm-based environments, eg. crop production, mixed farms, the red meat industry, the textile industry, dairy, fruit, and the fertiliser industry. Only two studies were found using the phrase "Lean farms". Future research should further investigate this concept and what a Lean farm would entail, by definition.

While there are several limitations to the study, it is important to understand the value that Lean philosophy can bring to any industry, especially agriculture. With the agricultural industry being one of the largest contributors to the South African GDP, it must continue to develop and grow for the betterment of the country. Lean offers an advantage that is worth more investigation and implementation in South Africa. Future research should explore the increased use of Lean-Agri in South Africa.

ABSTRACT

This research aims to identify the factors that affect the implementation of lean manufacturing (LM) and the influence of the identified factors on the operational performance in a food flavours manufacturing company in South Africa. A quantitative research approach was adopted to obtain an understanding of the lived experience on the shop floor. Current literature was reviewed, and a survey of a food flavours manufacturing company in South Africa was conducted to complement the knowledge gathered from the reviewed literature. Responses received represented 82% of the sample population and identified skills and training, leadership styles, change management, and employee involvement as critical factors influencing LM. Recommendations to management to enhance LM training, employee involvement, and communication were made as input to their LM strategy.

Keywords: Lean manufacturing, operational performance, factors, quantitative, food manufacturing

1 INTRODUCTION

The advent of the Covid-19 pandemic globally and the local national lockdown situation introduced a tumultuous environment where businesses have had to navigate to remain competitive or otherwise face the possibility of shutting down. Before the full recovery of the global economy, the manufacturing environment has been further compounded by the situation in Europe, originating from the Russian invasion of Ukraine, which has escalated quickly and is having a significant industry-specific impact on inputs and raw material costs. In the local environment, in South Africa, there is pressure as a result of the unreliability of power supply from ESKOM, reduced demand as result of the increase in cost of living as disposable income is eroded.

Companies around the world face numerous challenges in their efforts to survive and compete. Solutions to these challenges that manufacturing companies, including those in the food manufacturing industry face, must be found by adapting their management style and finding new manufacturing strategies [1]. Lean Manufacturing (LM) is one such strategy widely adopted by manufacturing companies to enhance performance and gain a competitive advantage by reducing waste (for example, in human effort, production space, time to market, and inventory).

The Toyota Motor Company is widely seen as the founder of LM, thanks to the work of Taiichi Ohno, they progressively synchronised all their processes simultaneously to give high quality, fast throughput, and exceptional productivity, known as the Toyota Production System (TPS), which shaped what we call Lean today [2]. The primary goals of LM are to reduce costs, improve quality, and deliver goods and services more quickly by eliminating activities that add no value, which Taiichi Ohno defines as waste [3], [4].

1.1 Research Problem

The context in which an organisation operates as well as the challenges that exist may affect the successful implementation process of LM. There is little research in Southern Africa, specifically referring to effective adoption of LM in the food industry. The effect of LM on the performance of operations is under-researched in Southern Africa [5].

Only a few food processing companies, such as Nestle Nigeria Plc, have adopted lean management practises that have demonstrated significant improvements in the proficiency and performance of operations. Perhaps the slow uptake of lean may be related to the sector’s products, processes, or plants [5].

The background against which this research seeks to investigate the contextual factors which affect the implementation of LM in the food flavours manufacturing industry as a management tool for cost reduction and to contribute to why there is a slow uptake of LM in South Africa’s Food Manufacturing sector.

Research Questions

- What are the factors that affect lean manufacturing at a Food Flavours Manufacturing Factory?
- What is the impact of these identified factors on the performance of lean manufacturing at a Food Flavours Manufacturing Factory?
- What recommendations can be made to the management of Food Flavours Manufacturing Factory, as input to their lean manufacturing strategy?

1.2 Hypotheses

The hypotheses for this study are outlined in Table 1.

Table 1: Hypotheses defined for this study

Research question	Hypotheses	Number	Nine Continuous Depended Variables
What are the factors that affect lean manufacturing at a Food Flavours Manufacturing Factory?	A relationship exists between the chosen continuous dependent variables of the research.	H1.1 to H1.9	Understanding of Lean Manufacturing (UM) Stakeholders Relations (SR) Supply Function (SF) Internal Operations (IO) Employee Involvement (EI) Leadership (LS) Change Management (CM) Employee Performance (EP) Organisational Commitment (OC)
What is the impact of these identified factors on the performance of lean manufacturing at a Food Flavours Manufacturing Factory?	Each one of the 9 chosen Continuous Dependent Variables mean rank scores are identical per gender categories.	H2.1 to H2.9

What is the impact of these identified factors on the performance of lean manufacturing at a Food Flavours Manufacturing Factory?	Each of the 9 selected Continuous Dependent Variables mean rank scores are identical per Education categories.	H6.1 to H6.9	

2 LITERATURE REVIEW

2.1 Introduction

LM practises have considerably increased the operational performance levels of companies concerning cost, quality, and delivery, particularly in the automobile industry [6]. Companies around the world face numerous challenges to survive and compete. Solutions to these challenges that manufacturing companies, including those in food manufacturing, face must be found by adapting their management styles and finding new manufacturing strategies [6]. Nonetheless, most of the available literature showed the historical narrow emphasis of the food manufacturing industry on matters of food security, neglecting excellence in operations [7]. Food manufacturing companies, understandably, are obligated [7] to comply with numerous strict food legislations such as the Food Safety System Certification (FSSC) 22000 and rigid customer demands; this may be due to their diverse industry methods [7;8].

2.2 Characteristics of the food industry context

The food sector companies are differentiated by different product structures. The raw materials are usually agricultural, such as milk, which can be used to produce various products, for example yoghurt, diverse types of milk, and cream products [9],[10]. Products differ as a result of differing customer requirements and specifications, which may be in the form of different packaging, labelling, or product recipes [11]. This diversity in product range necessitates an increase in the number of changeovers in the production process. Cleaning in Place (CIP) or cleaning-in-place is a very necessary and unique aspect of the food sector, performed between different batches to comply with quality requirements, adding to the changeover time [5;10]). In between recipe changes, it is mandatory to empty pipes and clean and sterilise equipment before new batches can be produced contamination-free [11]. Strict CIP and cleaning procedures in the food sector introduce challenges in the implementation of LM, especially where set-up time reduction is the required outcome, which can be achieved with a single minute of die exchange (SMED) tool.

2.3 Conceptual framework for the study

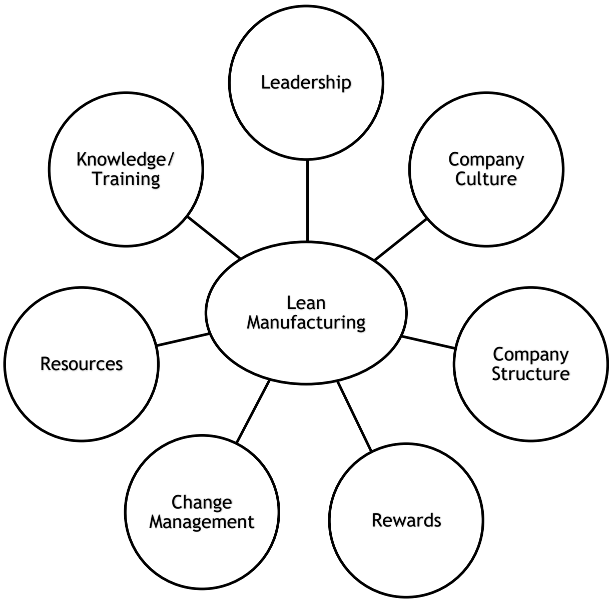

Figure 1: Factors affecting LM implementation

Lean outlines an essential framework that enhances efficiency and waste reduction in operations such as long setup times, equipment reliability through total productive maintenance, the elimination of rework and less conspicuous waste, and the reduction of variability exemplified by process times, delivery times, yield rates, staffing levels, and demand rates [14; 15]. Waste is any loss incurred by a company as a result of activities that cost it directly or indirectly and do not add value to a product or service [16], that is waste is anything that a customer is not willing to pay for.

2.4 Literature review

2.4.1 Factors affecting LM in South Africa

The South African industry faces enormous global competition from first-world countries such as Germany, owing to the latter's earlier adoption of LM techniques [17]. Despite the fact that the field of Industrial Engineering has existed in the country since 1961 and that the Lean philosophy is a symbol of Industrial Engineering, the practise has yet to be fully adopted in South African industry [17;18]. A realistic valuation of lean practise prototypes, including their effect on sustainable performance in the fruit and horticultural primary production context was conducted by [19]. They use a framework that is both holistic and comprehensive for LM and comprises the 10 dimensions of lean practice, which include supplier feedback, flow, pull, low set up, and total maintenance, to evaluate the prevalence of lean practices, including their correlation to farm size (plant), and sustainable performance in the context of the South African fruit horticultural sector. They conclude that the size of the farming operation impacts significantly on the level and depth of lean practise implementation as well as the extent of sustainable performance outcomes attained; the size of the farm (plant) is a significant factor of implementation, but this only applies for a subsection of lean practises [20;21].

2.4.2 Overview of factors affecting LM in Food Industry context

An analysis of empirical and theoretical literature by [22], there are three kinds of inhibiting factors: company inhibitors, human inhibitors, and technological inhibitors, distinguished as follow [22;23].

Table 2: Factors affecting LM implementation as compiled by [22]

Company inhibitor	Human inhibitor	Technological inhibitor
Plant size	Poor communication	Lack of technical resources
Company culture	Resistance to change	Absence of technological infrastructure
Lack of training	Job insecurity among employees	
High cost of implementation	Inability to see long term lean goals	
Lack of time	Low skill workers	
Insufficient labour resources	Willingness to achieve quick results	
No rewards and recognition	Suppliers not cooperating	
Lack of funds		
Failure of previous LM		

Adopted from: [22]

The most significant barriers to implementing lean are: (1) a lack of knowledge; (2) a lack of resources; (3) a lack of training; and (4) insufficient process control techniques for SMEs in the food processing industry [5;6].

It can be deduced from reviewed literature that company culture, management commitment, leadership style, change management (resistance to change), training, and resources are prevalent in the reviewed literature across borders.

2.4.3 Sources of waste

The three causes of waste which are related are mura, muri and muda, where when there is inconsistency in a process mura results; leading to the overburden of employees and equipment (muri) which results in non-value adding activities (muda) [4].

Taiicho Ohno from Toyota outlined the seven original types of waste based in the TPS, namely:

1. Transportation - the unwarranted transport of components under production.
2. Inventory - Heaps of components waiting to be completed or finished goods waiting to be shipped.
3. Motion – the unwarranted movement of people working on products.
4. Waiting – the unwarranted waiting by people to begin the next step.
5. Over-Processing the product with extra steps.
6. Over-Production of products not needed.
7. Defects in the product.
8. Underused people.

Table 3 is a representation of the relevant literature reviewed on LM in South Africa, including the food sector, is provided below:

Table 3: Lean management literature reviewed in South Africa

Author	Title	Source

Source: authors

This review was embarked on to assess and gain in-depth knowledge and understanding of the enabling and inhibiting factors of lean implementation that encourage or discourage LM in the food industry. The identified influential factors across borders from the reviewed literature, include:

- Company culture
- Leadership
- Skills and Training
- Company Structure
- Resources
- Multifunctioning Teams
- Compensation/ Rewards

- Change Agent

3 RESEARCH METHODOLOGY

The method of research is depicted as the map which gives direction to how the goals of the research are executed ensuring that the data gathering procedure is orderly and coordinated [23].

3.1 Quantitative Research Design

Saunders, Lewis and Thornhill [25] developed the Research Onion, which is used to guide this research design by adopting an approach that is philosophical, influenced by the positivistic philosophy.

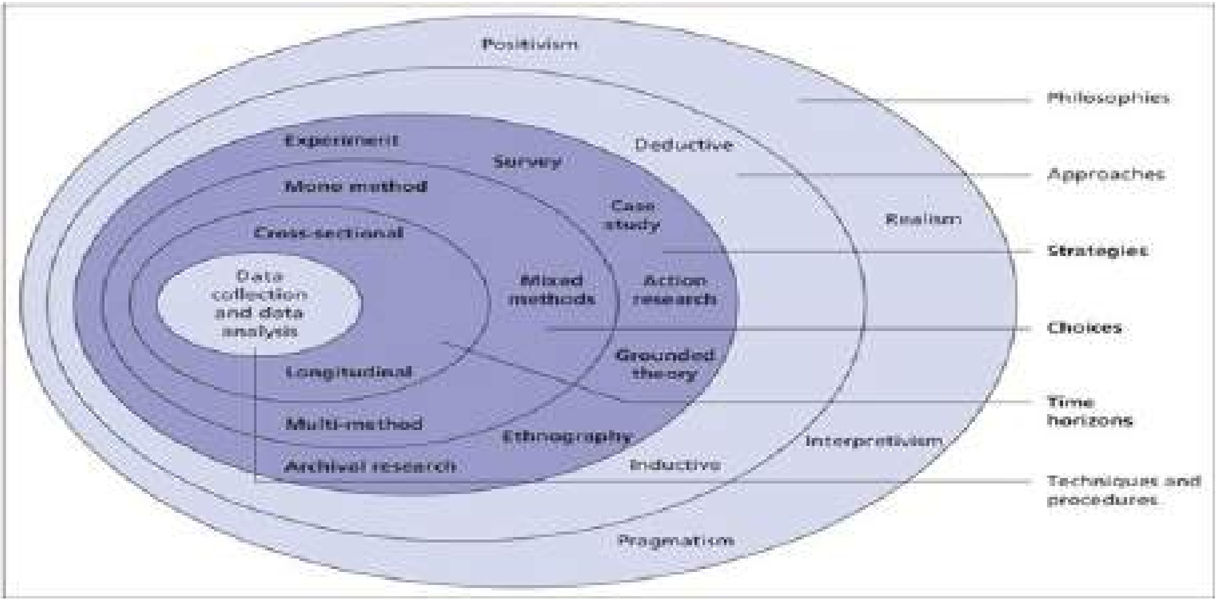

Figure 2: The Research Onion

Adopted from: Saunders, Lewis and Thornhill [25]

3.1.1 Philosophy adopted

The opinion of positivists is based on the commonality of human nature, which is not reliant on one's beliefs, culture, or historical background which will be adopted for this study [23].

3.1.2 Research approach

This approach was deductive and tested theory as it applied to the South African food manufacturing industry. The approach allows for the scrutiny of the problem and the context, resulting in the deduction of both the cause and effect; this process assists in investigating the phenomenon in its normal setting with a focus on cases that are contemporary [24].

3.1.3 Research strategy

The variables identified in the review of previous literature were tested in the context of the food factory in the South African environment by conducting a survey, a quantitative tool, at the case company. A survey questionnaire with pre-set questions relevant to LM was used to explore factors in the literature. Surveys are frequently used in business management research because they are reliable and allow for large quantities of data to be gathered [25;26].

3.1.4 Research choice

The mono method, as outlined in the research onion, was adopted for this research due to the time constraints of the research period.

3.1.5 Techniques and procedures

The techniques adopted after the collection of data via the survey to analyse the data were incorporate descriptive statistical analysis, which was conducted first, and then inferential statistical analysis [27;28].

This study used the systematic, sequential approach depicted in Figure 3. Beginning with a review of the literature.

Figure 3: Quantitative Research Road Map

Source: authors

3.2 Population

The population was not made up of subject matter experts but rather ordinary, experienced employees in their areas of expertise who are actively involved at the operations level, 82 employees out of the 100 completed the online surve.

Table 4: Target Population

Department	No of participants
Liquids & Powders plants	50
Creative and Development	10
QC/ QA	10
Customer service	12
Warehouse/ Stores	8
Sales	10

3.3 Sample

Propagates sampling as a process that selects a subset that represents the population, which allows the study to extricate significant information after which conclusions may be extrapolated [29;30]. This approach was used to achieve the target sample.

3.3.1 Convenience Sampling

Convenience Sampling - a technique for compiling information from a group of participants to whom the researcher has easy access. It is a commonly used tool as it is quick, straightforward, and economical. Participants are easy to approach in most cases to take part in the sample [31].

3.4 Data collection

This research used an online questionnaire, and made on-site observations through Gemba walks (Gemba walks a Japanese term denote the action of going to see the actual process, understand the work, ask questions and learn) [5], before and in anticipation of LM implementation to ascertain the value and obtain an overview of how the processes and operations will change subject to LM implementation [30]. As LM manufacturing has already been implemented, all employees were familiar with the terminology of lean.

3.5 Data Analysis

Content analysis was carried out to ascertain patterns, inclinations, preconceptions and premises. First, descriptive statistical analysis was conducted, followed by inferential statistical analysis [30].

3.5.1 Descriptive Statistics

Descriptive statistical analysis was conducted, where the collected quantitative data was summarised in graphics and tables.

3.5.2 Inferential Statistics

Inferential statistics is described as being involved with formulating interpretations founded on relations discovered in the sample and relations in the population [31].

3.6 Validity and Reliability

Validity and reliability were significant constructs utilised in determining whether suggestions in research are based on legitimate, dependable, precise, and credible data compilation and methods of analysis, must be both repeatable and dependable for them to be contemplated as being reliable [30].

3.7 Ethical Consideration

Ethical consideration was given to respect the respondent's rights in the interviews and during the Gemba walks and questionnaires; this includes how they were approached and interviewed, consent forms that were signed to show agreement to participate, and the data collected and used for this research.

4 RESULTS AND FINDINGS

The focus of the research was to establish the factors that affect the implementation of LM in a food flavours manufacturing factory. The research's objective was to provide senior management with insight into the internal factors that influence the implementation of LM in the company and to make recommendations that offer potential solutions to improve the company's competitive advantage. The quantitative study will inform management of the empirically developed and tested factors are indeed important and should be considered.

4.1 Limitations

This research is restricted to the case company, which is its main limitation, the response rate received was satisfactory (82 responses of 100) for the population however this may not be representative of an entire industry. The research approach and its findings are considered to be sound however, widening the investigation to include other companies in the food flavours manufacturing industry in South Africa would strengthen the validity and generalisation of the findings. The study aimed to provide insight to the internal factors that influence LM implementation, however it is limited in providing insight on how the company could benefit quantitatively.

4.2 Descriptive statistical analysis

The outcomes of the descriptive statistical analysis were presented, and the collected quantitative data was summarised in tables. The data was collected from a an identified population of 300 using the online survey questionnaire which was emailed to the respondents. In addition, he identified population for the study was 300 and the responses received were 82.

4.2.1 Continuous Improvement (CI) Methods Awareness

The CI methods awareness are the methods that the population is familiar with and use, which include Total Quality Management (TQM), Lean Manufacturing (LM), and Six Sigma, a reflection of improvement activities in the food industry. As LM manufacturing has already been implemented, all operational employees were familiar and trained with the terminology of lean.

The set of questions that evaluated Implemented CI Methods are presented in Table 5.

Table 5: Implemented CI Methods (n = 82)

Methods	Not intended to be used / unknown	Planned for use in subsequent year	Planned for use in 3 years	Already in use
Quality mission statement	8	3	3	68
	10%	4%	4%	83%
Quality vision statement	10	2	3	67
	12%	2%	4%	82%
Root Cause Analysis (Fishbone diagram)	16	1	3	62
	20%	1%	4%	76%
Standardised work sheet	20	4	3	55
	24%	5%	4%	67%
Standard work	21	3	4	54
	26%	4%	5%	66%
5 – why analysis	23	1	4	54
	28%	1%	5%	66%
Visual Management	21	3	5	53
	26%	4%	6%	65%
Notification system for quality and process problems (Andon)	28	3	4	47
	34%	4%	5%	57%
Just in time	27	4	7	44

Methods	Not intended to be used / unknown	Planned for use in subsequent year	Planned for use in 3 years	Already in use
	33%	5%	9%	54%
Plan-do-check-act PDCA cycle	32	3	6	41
	39%	4%	7%	50%
5S - method	38	4	2	38
	46%	5%	2%	46%
Value Stream Mapping	30	7	9	36
	37%	9%	11%	44%
Levelling production and schedules (heijunka)	39	0	8	35
	48%	0%	10%	43%
Pull system	46	5	6	25
	56%	6%	7%	30%
Takt Time	43	7	8	24
	52%	9%	10%	29%
Error Proofing (poka yoke)	46	10	6	20
	56%	12%	7%	24%
Gemba	56	1	7	18
	68%	1%	9%	22%
Kanban system	53	5	7	17
	65%	6%	9%	21%
Single minute exchange of die (change overs)	55	4	8	15
	67%	5%	10%	18%

The results indicate that the company practises TQM like many in the food industry, with 83% of respondents being familiar with the company's quality mission statement and 82% being familiar with the quality vision statement.

4.2.2 Understanding of Lean Manufacturing

Table 6 exhibits the set of questions that evaluated understanding of LM, the scale 1 to 5 represents the degree to which the respondents agreed or disagreed, with 1 being strongly disagree to 5 strongly agree.

Table 6: Understanding of LM

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
I understand the concept of lean management.	4	0.91	3	2	10	45	22	82
			4%	2%	12%	55%	27%	100%
I am aware of this lean practice, in our company	4	1.02	4	7	18	39	14	82
			5%	9%	22%	48%	17%	100%
Our company is currently implementing lean manufacturing practices	4	0.92	2	5	29	32	14	82
			2%	6%	35%	39%	17%	100%
Our company has been implementing many of the lean	4	0.93	4	2	28	37	11	82

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
manufacturing practices even though we do not call it lean			5%	2%	34%	45%	13%	100%
My colleagues have adequate knowledge of Lean Manufacturing	3	1.04	6	10	31	27	8	82
			7%	12%	38%	33%	10%	100%

Standard deviation (SD) is a measure of how dispersed the data is in relation to the mean. Low, or small, standard deviation indicates data are clustered tightly around the mean, and high, or large, standard deviation indicates data are more spread out [31].

The respondents (55%) agree they have an understanding of LM, 48% agree that they are only aware of the company's LM practice. The respondents (55%) agree they have an understanding of LM, 48% agree that they are only aware of the company's LM practice.

4.2.3 Lean Manufacturing

With regards to LM, many of the respondents indicated that the employee training programme on LM is not working (Mo = 2, SD = 1.07). This offers a possible solution to the question of why there is not more emphasis on operational improvements that could result from successful LM implementation.

The set of questions that measured LM is presented in Table 7.

Table 7: Lean Manufacturing

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
8.5: Our company is currently implementing HACCP	5	0.92	2	1	13	29	37	82
			2%	1%	16%	35%	45%	100%
8.6: Our company is currently implementing FSSC 22000	5	0.89	2	0	15	32	33	82
			2%	0%	18%	39%	40%	100%
8.7: Our company is currently implementing NFS	4	0.95	2	2	28	28	22	82
			2%	2%	34%	34%	27%	100%
8.8: Our company is currently implementing ISO 9001: 2015	4	0.88	2	1	17	38	24	82
			2%	1%	21%	46%	29%	100%
8.9: Our company is currently implementing ISO 45000	4	0.99	3	3	28	29	19	82
			4%	4%	34%	35%	23%	100%
11: Do you think your employee training program on Lean Manufacturing is working?	2	1.07	10	29	26	12	5	82
			12%	35%	32%	15%	6%	100%
12: You are involved in problem identification & improvement of	4	1.03	4	10	18	39	11	82

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
processes (be they Production; innovation; sales; procurement etc) of the company?			5%	12%	22%	48%	13%	100%
13: To what extent can the worker involvement in Lean Manufacturing (waste elimination) programs in your workplace be explained?	3	1.03	4	7	32	25	14	82
			5%	9%	39%	30%	17%	100%
14: Do you think the opinions and suggestions of employees are given due consideration?	3	1.26	6	16	32	6	22	82
			7%	20%	39%	7%	27%	100%

4.2.4 Stakeholders relationship scale

The set of questions that evaluated Stakeholders Relations is presented in Table 8.

Table 8: Stakeholders Relationship Scale

Customer Relations	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
We are in frequent contact with our customers.	4	0.92	3	3	10	46	20	82
			4%	4%	12%	56%	24%	100%
Our customers give us feedback on quality and delivery performance.	4	0.84	1	3	11	41	26	82
			1%	4%	13%	50%	32%	100%
We conduct customer satisfaction surveys regularly.	3	0.97	3	4	35	25	15	82
			4%	5%	43%	30%	18%	100%
We are in frequent contact with our Suppliers.	4	0.74	1	0	15	46	20	82
			1%	0%	18%	56%	24%	100%

The majority of the respondents strongly agree that they are in frequent contact with their customers (Mo = 4, SD = 0.92) and that they are in frequent contact with their suppliers (Mo = 4, SD = 0.94). The respondents agree that the customers give them feedback on quality and delivery performance (Mo = 4, SD = 0.84). Customer gratification is influenced by superior product quality, reasonable prices, and on-time supplies, [32,33].

4.2.5 Supply function

There are various requirements for the implementation of LM in a company, one of which is that the company must integrate its suppliers and customers [33].

The set of questions that measured Supply function is presented in Table 9.

Table 9: Supply Function Scale

Supplier Management	**Mode**	**SD**	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	**N**
Our key suppliers deliver to our factory on just-in-time basis.	4	0.93	1	5	28	29	19	82
			1%	6%	34%	35%	23%	100%

Supplier Management	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
We take steps to reduce the number of suppliers in each category to reduce raw material variations.	4	0.92	2	5	29	32	14	82
			2%	6%	35%	39%	17%	100%
Our purchasing / supply function is centralised.	4	0.77	1	0	33	35	13	82
			1%	0%	40%	43%	16%	100%

The majority of the respondents agree that the purchasing/ supply function is centralised (Mo = 4, SD = 0.77) and that they take steps to reduce the number of suppliers in each category in order to reduce raw material variations. (Mo = 4, SD = 0.92).

4.2.6 Internal Operations

The set of questions that measured Internal Operations is presented in Table 10.

Table 10: Internal Operations Scale

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
We use the pull production system.	3	0.91	1	6	41	20	14	82
			1%	7%	50%	24%	17%	100%
We use Kanban, squares, or containers of signals for production control.	3	0.93	3	9	41	20	9	82
			4%	11%	50%	24%	11%	100%
Production at station is pulled by the current demand of the next station.	3	0.86	1	8	40	24	9	82
			1%	10%	49%	29%	11%	100%
Products are classified into groups with similar routing requirements.	4	0.83	1	4	26	39	12	82
			1%	5%	32%	48%	15%	100%
Product families determine our factory lay out.	4	0.92	1	7	28	31	15	82
			1%	9%	34%	38%	18%	100%
We are working to lower set up times in our plant from one batch to the next.	3	0.89	2	4	33	31	12	82
			2%	5%	40%	38%	15%	100%
We monitor our production cycle time to respond quickly to customer requests.	4	0.91	2	5	20	40	15	82
			2%	6%	24%	49%	18%	100%
Our employees practice setups to reduce required time.	3	0.99	2	12	29	27	12	82
			2%	15%	35%	33%	15%	100%
Our processes on the shop floor are currently under Statistical Process Control.	3	1.02	3	7	35	21	16	82
			4%	9%	43%	26%	20%	100%
We use charts to show defect rates on the shopfloor.	3	0.92	4	8	42	21	7	82
			5%	10%	51%	26%	9%	100%

A total of 48% of the respondents agree that products are classified into groups with similar routing requirements (Mo = 4, SD = 0.83), 49% agree that they monitor the production cycle time to respond quickly to customer requests.

4.2.7 Employee Involvement

The set of questions that evaluated Employee Involvement is presented in Table 11.

Table 11: Employee Involvement Scale

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
Shopfloor employees undergo cross-functional training.	3	0.98	4	6	32	29	11	82
			5%	7%	39%	35%	13%	100%
Shopfloor employees are crucial to problem-solving teams.	4	0.98	3	3	20	35	21	82
			4%	4%	24%	43%	26%	100%
Shopfloor employees lead product/process improvement efforts.	3	1.10	4	9	26	25	18	82
			5%	11%	32%	30%	22%	100%
I welcome change most of the time when it is clearly communicated.	4	0.64	0	0	7	38	37	82
			0%	0%	9%	46%	45%	100%

45% of the respondents strongly agree that they welcome change most of the time when it is clearly communicated (Mo = 4, SD = 0.64) and 43% agree that shopfloor employees are crucial to problem-solving teams (Mo = 4, SD = 0.98). Only 39% of the respondents neither agreed nor disagreed that shopfloor employees undergo cross-functional training (Mo=3, SD=0.98).

4.2.8 Leadership

In a study in Morocco, the participants interviewed by Farissi et al [36] identified the main inhibiting factors and attributed 80% of them to a lack of managerial commitment.

The set of question set that measured Leadership is presented in Table 12.

Table 12: Leadership Scale (n = 82)

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
I have a positive working relationship with my line manager.	4	0.84	2	1	6	40	33	82
			2%	1%	7%	49%	40%	100%
My job allows me to advance my career.	4	1.07	3	7	12	33	27	82
			4%	9%	15%	40%	33%	100%
My manager is aware of my work problems and obstacles.	4	0.98	3	3	18	36	22	82
			4%	4%	22%	44%	27%	100%
Management behaviour in our company is related to subordinate satisfaction and task commitment.	4	0.91	3	3	29	35	12	82
			4%	4%	35%	43%	15%	100%
	4	1.11	3	11	21	27	20	82

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
Management behaviour in our company is related to employee motivation.			4%	13%	26%	33%	24%	100%
Managers encourage the creation of new knowledge and ideas via the use of academic motivation.	4	1.04	4	7	25	31	15	82
			5%	9%	30%	38%	18%	100%
Management enhances employee competence and encourages transformation.	4	1.02	3	8	15	39	17	82
			4%	10%	18%	48%	21%	100%
Managers in the company build exceptional teams and influence performance.	4	1.01	3	7	21	35	16	82
			4%	9%	26%	43%	20%	100%
Employees feel trust, admiration, loyalty and respect toward their manager.	4	1.01	2	8	23	31	18	82
			2%	10%	28%	38%	22%	100%
The company actively promotes a culture of empowerment and motivation.	4	1.08	3	8	19	30	22	82
			4%	10%	23%	37%	27%	100%

Only 40% of the respondents strongly agree that they have a positive working relationship with my line manager (Mo = 4, SD = 0.84).

4.2.9 Change Management

One of the most important success factors of the LM implementation in the shoe factory study was cultural change management,[33].

The set of questions that measured Change Management is presented in Table 13.

Table 13: Change Management Scale (n = 82)

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
Our company has a management of change policy which I am aware of.	4	1.11	5	6	24	28	19	82
			6%	7%	29%	34%	23%	100%
Our company communicates change to employee at the beginning (outset) of the journey.	4	1.09	4	10	14	37	17	82
			5%	12%	17%	45%	21%	100%
Our company communicates change effectively so that all employees affected understand.	4	0.95	1	9	17	38	17	82
			1%	11%	21%	46%	21%	100%
Our company provides training for the change where necessary.	4	0.87	2	3	8	45	24	82
			2%	4%	10%	55%	29%	100%
Our company communicates change effectively so that all employees are on board, cooperate and are supportive.	4	0.99	2	6	21	33	20	82
			2%	7%	26%	40%	24%	100%
	4	0.98	3	4	25	33	17	82

Our company motivates its employees throughout the change process.			4%	5%	30%	40%	21%	100%

Of the respondents 55% agree that our company provides training for the change where necessary (Mo = 4, SD = 0.87), and 46% agree the company communicates change effectively so that all employees affected understand (Mo = 4, SD = 0.95). This may suggest that the change management policy may not be well communicated, especially where more than 50% of the respondents have been with the company for less than 5 years.

4.2.10 Employee Performance Scale

Lean leadership may be thought of as a manner of sustaining and refining employee performance in lean production systems.

The set of questions that evaluated Employee Performance is presented in Table 14 below.

Table 14: Employee Performance Scale (n = 82)

	Mode	SD	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	N
My Colleagues adequately complete their assigned duties.	4	0.79	0	5	10	46	21	82
			0%	6%	12%	56%	26%	100%
My Colleagues execute extra effort to fulfil their tasks beyond expectation.	4	0.80	1	4	12	49	16	82
			1%	5%	15%	60%	20%	100%
My Colleagues always strive to achieve departmental goals.	4	0.84	1	4	9	44	24	82
			1%	5%	11%	54%	29%	100%
My Colleagues enjoy sharing information and skills with other colleagues.	4	0.94	2	3	16	36	25	82
			2%	4%	20%	44%	30%	100%
My Colleagues adhere to informal rules to maintain order.	4	0.81	1	3	19	44	15	82
			1%	4%	23%	54%	18%	100%
My Colleagues enjoy contributing solutions to solve departmental problems.	4	0.93	3	3	14	43	19	82
			4%	4%	17%	52%	23%	100%
My Colleagues are committed to their work.	4	0.83	2	1	7	42	30	82
			2%	1%	9%	51%	37%	100%
My Colleagues value interpersonal relationships.	4	0.84	2	2	14	46	18	82
			2%	2%	17%	56%	22%	100%
My Colleagues welcome feedback to help improve performance	4	0.89	2	3	12	43	22	82
			2%	4%	15%	52%	27%	100%

The majority of the respondents (60%) agree that, My Colleagues execute extra effort to fulfil their tasks beyond expectation (Mo = 4, SD = 0.80).

4.2.11 Organisational Commitment

It is the actions of management to deliberately promote a culture of CI that give rise to a higher commitment of employees to maintain lean, cooperation among cross-functional teams to attain process targets, and a keenness of the workforce to advance their performance continuously [37].

The set of questions that measured Organisational Commitment is presented in Table 15.

Table 15: Organisational Commitment Scale (n = 82)

	Mode	**SD**	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	**N**
During the last 3 months, how do you rate your overall job satisfaction?	5	1.06	2	6	8	21	45	82
			2%	7%	10%	26%	55%	100%
A person should always be loyal to the organisation he/she works in	5	0.79	1	1	8	36	36	82
			1%	1%	10%	44%	44%	100%
One of the main reasons for me to continue to work in this company is loyalty and moreover moral obligations	4	0.95	1	5	20	31	25	82
			1%	6%	24%	38%	30%	100%
I can leave my job if I get a better job offer	5	1.13	3	10	22	23	24	82
			4%	12%	27%	28%	29%	100%
Spending most of his/her career in one institution is good for a worker	4	1.09	5	18	25	25	9	82
			6%	22%	30%	30%	11%	100%
It will not be logical to commit myself emotionally to one organisation	3	1.03	5	9	39	18	11	82
			6%	11%	48%	22%	13%	100%
As for my opinion, being loyal to the organisation is important	4	0.76	0	1	14	36	31	82
			0%	1%	17%	44%	38%	100%

The majority of the respondents (55%) strongly agree that they experienced overall job satisfaction during the last 3 months (Mo = 5, SD = 1.06), Job satisfaction in the company seems to be very good.

4.3 Analysis Inferential Statistical

The results of the inferential statistical methods are utilised to analyse the gathered quantitative data. Although the scales of this study were subjected to factor analysis, the results were not recorded.

4.3.1 Hypothesis testing

The first set of hypotheses was to determine the relationship between the eight continuous dependent variables and the dependent variable Internal Operations (IO).

Hypothesis H1.1 to H1.9

Hypothesis $H0_{1.1}$ to $H0_{1.9}$: There is no relationship between the selected continuous dependent variables of the study

It is clear that a significant, positive correlation exists between all the selected continuous dependent variables of the study. Upon this finding, the null hypotheses $H0_{1.1}$ to $H0_{1.9}$ are discarded, accepting the alternate hypotheses which denoted that a positive relationship exists between all the chosen continuous dependent variables of the study.

Hypothesis H2.1 to H2.9

Hypothesis $H0_{2.1}$ to $H0_{2.9}$: Each one of the 9 chosen Continuous Dependent Variables mean rank scores are not identical per gender category

Table 16: Gender Group Mean Score Assessment (n = 82)

	Dependent Variables	Mann-Whitney U	Wilcoxon W	Z	Asymp. Sig. (2-tailed)
H2.1	Understanding of Lean Manufacturing (UM)	588.000	1329.000	-2.318	**.020**
H2.2	Stakeholders Relations (SR)	669.000	1410.000	-1.570	.117
H2.3	Supply Function (SF)	687.000	1428.000	-1.405	.160
H2.4	Internal Operations (IO)	698.000	1439.000	-1.287	.198
H2.5	Employee Involvement (EI)	552.000	1293.000	-2.673	**.008**
H2.6	Leadership (LS)	716.000	1457.000	-1.117	.264
H2.7	Change Management (CM)	638.000	1379.000	-1.848	.065
H2.8	Employee Performance (EP)	627.000	1368.000	-1.953	.051
H2.9	Organisational Commitment (OC)	536.000	1277.000	-2.801	**.005**

Understanding of Lean Manufacturing: The female group has a median score of 3.4, while the male group has a score of 3.9. This means that men report a greater level Understanding of Lean Manufacturing than women.

Employee Involvement: The median score for Females is (3.17) and Males is (4.00). This means that males report a higher Employee Involvement than females.

Organisational Commitment: The median score for Females is (3.80) and Males is (4.30). This means that the males report a higher Organisational Commitment that females.

Hypothesis H3.1 to H3.9

Hypothesis $H0_{3.1}$ to $H0_{3.9}$: **Each one of the 9 chosen Continuous Dependent Variables mean rank scores are not identical per Age category**

The non-parametric Kruskal-Wallis Test (for testing more than two variables) (Pallant, 2020) [28] was applied to establish if there are meaningful variances in categorical variables' mean scores.

Table 17: Age Group Mean Score Comparison (n = 82)

	Dependent Variables	Chi-Square	df	Asymp. Sig.
H3.1	Understanding of Lean Manufacturing (UM)	4.344	3	.227
H3.2	Stakeholders Relations (SR)	2.024	3	.567
H3.3	Supply Function (SF)	5.504	3	.138
H3.4	Internal Operations (IO)	2.966	3	.397
H3.5	Employee Involvement (EI)	3.617	3	.306
H3.6	Leadership (LS)	5.236	3	.155
H3.7	Change Management (CM)	4.460	3	.216
H3.8	Employee Performance (EP)	1.620	3	.655
H3.9	Organisational Commitment (OC)	9.247	3	**.026**

Due to space constraints, only results of significance are shown in detail. Only one variance of statistical significance was found between the dependent variables across the categorical independent variable age groups.

Hypothesis H4.1 to H4.9

Hypothesis $H0_{4.1}$ to $H0_{4.9:}$ Each one of the 9 chosen Continuous Dependent Variables mean rank scores are not identical per Job Level category

The non-parametric Kruskal-Wallis Test (for testing more than two variables) was applied to establish if there are relevant variances in categorical variables' mean scores. The outcomes of the means rank-score comparison of the categories of job level on the nine dependent variables of the study are reported in Table 18.

Table 18: Job Level Group Mean Score Comparison (n = 82)

	Dependent Variables	Chi-Square	df	Asymp. Sig.
H4.1	Understanding of Lean Manufacturing (UM)	4.735	3	.192
H4.2	Stakeholders Relations (SR)	10.380	3	**.016**
H4.3	Supply Function (SF)	9.941	3	**.019**
H4.4	Internal Operations (IO)	8.116	3	**.044**
H4.5	Employee Involvement (EI)	4.400	3	.221
H4.6	Leadership (LS)	1.375	3	.711
H4.7	Change Management (CM)	9.907	3	**.019**
H4.8	Employee Performance (EP)	2.698	3	.441

H4.9	Organisational Commitment (OC)	6.855	3	.077

Four statistically significant differences were found between the dependent variables and the categorical independent variable gender groups.

Stakeholders Relations (SR): Using the Kruskal-Wallis Test post hoc analysis (see Table 19) reveals that the distribution of Stakeholders Relations is not identical across categories of Job Level as there is a statistically significant difference (n = 82; p = 0.016) in categories of Job Level with Stakeholders Relations.

Table 19: Stakeholders Relations Comparison between Current Job Level

Sample 1 - Sample 2	Test Statistic	Std Error	Std Test Statistic	Sig	Adj-Sig
Junior Management (supervisory)-Senior or Middle management	-9.187	7.349	-1.250	.211	1.000
Junior Management (supervisory) - Operational	-15.135	6.535	-2.316	.021	.123
Junior Management (supervisory) - Support Staff	-23.827	8.004	-2.977	.003	.017
Senior or Middle management - Operational	5.948	7.349	.809	.418	1.000
Senior or Middle management - Support Staff	-14.640	8.681	-1.686	.092	.550
Operational – Support Staff	-8.692	8.004	-1.086	.277	1.000

The outcomes of the Kruskal-Wallis test post hoc analysis showed that there are statistically significant differences in the Stakeholders Relations levels between the Job Level categories Junior management and Supporting Staff. This means Supporting Staff gives higher Stakeholders Relations scores than Junior management (supervisory).

Supply Function (SF): Table 20, reflects on the analysis of the Kruskal-Wallis Test which reveals that the distribution of Supply Function is not identical across categories of Job Level which resulted from a statistical significant variance (n = 82; p = 0.019) in categories of Job Level with Supply Function.

Table 20: Supply Function Comparison between Current Job Level

Sample 1-Sample 2	Test Statistic	Std Error	Std Test Statistic	Sig	Adj-Sig
Junior Management (supervisory)-Senior or Middle management	-12.552	7.326	-1.713	.087	.520
Junior Management (supervisory) - Support Staff	-15.346	7.978	-1.923	.054	.327
Junior Management (supervisory) - Operational	-19.904	6.514	-3.055	.002	.013
Senior or Middle management - Support Staff	-2.794	8.654	-.323	.747	1.000
Senior or Middle management - Operational	7.352	7.326	1.004	.316	1.000
Support Staff - Operational	4.558	7.978	.571	.568	1.000

The outcomes of the analysis using the Kruskal-Wallis Test post hoc revealed that the Supply Function levels differed statistically substantially (p = 0.013) between the Job Level categories Junior management (supervisory) (Mean rank = 30.15, n = 26) and Operational (Mean rank = 50.06, n = 26). This means Operational Staff gives higher Stakeholders Relations scores than Junior management (supervisory).

Internal Operations (IO): The Kruskal-Wallis Test post hoc analysis revealed that the distribution of Internal Operations differs across classes of Job Level as there is a statistical difference of significance in classes of Job Level with Internal Operations. Based on this information it seems that employees on a lower job level give a higher score for Internal Operations.

Change Management (CM): Table 21 reflects on the Kruskal-Wallis Test post hoc analysis reveals that the distribution of Change Management is not identical across classes of Job Level as there exists a statistically significant difference (n = 82; p = 0.019) in classes of Job Level with Change Management.

Table 21: Change Management Comparison between Current Job Level

Sample 1 – Sample 2	Test Statistic	Std Error	Std Test Statistic	Sig	Adj-Sig
Junior Management (supervisory)-Senior or Middle management	-10.768	7.402	-1.455	.146	.874
Junior Management (supervisory) - Operational	-15.577	6.582	-2.367	.018	.108
Junior Management (supervisory) - Support Staff	-23.058	8.061	-2.860	.004	.025
Senior or Middle management - Operational	4.809	7.402	.650	.516	1.000
Senior or Middle management - Support Staff	12.290	8.743	-1.406	.160	.959
Support Staff - Operational	-1.7481	8.061	-9.28	.353	1.000

The outcomes of the Kruskal-Wallis Test post hoc analysis revealed that there exists a statistically significant difference in Change Management levels (p = 0.025) between the Job Level categories Junior management (supervisory) (Mean rank = 30.67, n = 26) and Supporting Staff (Mean rank = 53.73, n = 13). Supporting staff give higher scores for Change Management than Junior management (supervisory).

Hypothesis H5.1 to H5.9

Hypothesis $H0_{5.1}$ to $H0_{5.9}$: Each one of the 9 chosen Continuous Dependent Variables mean rank scores are not identical per Current Position Tenure category

Reported in Table 22 below are the outcomes of the means rank scores comparison of the categories of Current Position Tenure on the nine dependent variables of the research.

Table 22: Current Position Tenure Group Mean Score Comparison (n = 82)

	Dependent Variables	Chi-Square	df	Asymp. Sig.
H5.1	Understanding of Lean Manufacturing (UM)	4.228	3	.238
H5.2	Stakeholders Relations (SR)	2.575	3	.462

	Dependent Variables	Chi-Square	df	Asymp. Sig.
H5.3	Supply Function (SF)	6.174	3	.103
H5.4	Internal Operations (IO)	2.325	3	.508
H5.5	Employee Involvement (EI)	2.221	3	.528
H5.6	Leadership (LS)	3.730	3	.292
H5.7	Change Management (CM)	3.083	3	.379
H5.8	Employee Performance (EP)	2.612	3	.455
H5.9	Organisational Commitment (OC)	3.218	3	.359

The Kruskal-Wallis Test revealed that the distribution of nine dependent variables is same across categories of current position tenure as there is no difference ($n = 82$; $p > 0.05$) in categories of current position tenure with the nine dependent variables.

Hypothesis H6.1 to H6.9

Hypothesis $H0_{6.1}$ to $H0_{6.9}$: Each of the 9 selected Continuous Dependent Variables mean rank scores are not identical per Education category

Table 23 below reflects on the outcomes of the means rank scores comparison of the categories of Education on the nine dependent variables of the research.

Table 23: Education Group Mean Score Comparison (n = 82)

	Dependent Variables	*Chi-Square*	*df*	*Asymp. Sig.*
H6.1	*Understanding of Lean Manufacturing (UM)*	*9.370*	*3*	***.125***
H6.2	*Stakeholders Relations (SR)*	*9.300*	*3*	***.026***
H6.3	*Supply Function (SF)*	*3.579*	*3*	*.311*
H6.4	*Internal Operations (IO)*	*4.703*	*3*	*.195*
H6.5	*Employee Involvement (EI)*	*5.570*	*3*	*.134*
H6.6	*Leadership (LS)*	*7.152*	*3*	*.067*
H6.7	*Change Management (CM)*	*8.534*	*3*	***.036***
H6.8	*Employee Performance (EP)*	*3.123*	*3*	*.373*
H6.9	*Organisational Commitment (OC)*	*16.077*	*3*	***.001***

Four statistically significant differences were found between the dependent variables across the categorical independent variable gender groups.

Understanding of Lean Manufacturing: The Kruskal-Wallis Test post hoc analysis revealed that the distribution of Understanding of Lean Manufacturing is different across categories of Education as there exists a statistically significant difference ($n = 82$; $p = 0.025$) in categories of Education with Understanding of Lean Manufacturing.

Stakeholders Relations: Table 24 below revealed that the distribution of Stakeholders Relations differs across categories of Education as there exists a statistically relevant difference ($n = 82$; $p = 0.026$) in categories of Education with Stakeholders Relations.

Table 24: Stakeholders Relations Comparison between Education

Sample 1-Sample 2	Test Statistic	Std Error	Std. Test Statistic	Sig	Adj. Sig
Undergraduate-Diploma/ degree	5.150	8.291	.621	.534	1.000
Undergraduate-Master's degree or equivalent or more	13.900	12.168	1.142	.253	1.000
Undergraduate-Grade 12 or less	21.338	8.869	2.406	.016	.097
Diploma/ Degree-Master's degree or equivalent or more	-8.750	10.284	.851	.395	1.000
Diploma/ Degree-Grade 12 or less	-16.188	6.029	-2.685	.007	.044
Master's degree or equivalent or more-Grade 12 or less	7.438	10.755	.692	.489	1.000

Change Management: The outcomes of the Kruskal-Wallis Test post hoc analysis utilising a Dunn's technique with Bonferroni correction for multiple comparisons revealed that the distribution of Change Management is not the same across categories of Education as there exists a statistically significant difference (n = 82; p = 0.036) in categories of Education with Change Management.

Organisational Commitment: Table 25 below revealed that the distribution of Organisational Commitment is dissimilar across categories of Education as there exists a statistically significant difference (n = 82; p = 0.001) in categories of Education with Organisational Commitment.

Table 25: Organisational commitment comparison between education

Sample 1-Sample 2	Test Statistic	Std. Error	Std. Test Statistic	Sig	Adj. Sig
Diploma/Degree-Undergraduate	-11.910	8.345	-1.427	.154	.921
Diploma/Degree-Master's degree or equivalent or more	-14.976	10.351	-1.447	.148	.888
Diploma/Degree-Grade 12 or less	-23.955	6.069	-3.947	.000	.000
Undergraduate-Master's degree or equivalent or more	3.067	12.247	.250	.802	1.000
Undergraduate-Grade 12 or less	12.048	8.927	1.349	.177	1.000
Master's degree or equivalent or more-Grade 12 or less	8.979	10.825	.829	.407	1.000

On the basis of this outcome the alternate hypothesis is discarded and the null hypotheses 6.9 is acknowledged which stated that Organisational Commitment mean rank scores differ per Education category.

5 DISCUSSION AND SUMMARY OF FINDINGS FROM THE REVIEW OF LITERATURE

There are numerous requirements for the successful implementation of lean practises in a company, one of which is that there ought to be a strong commitment from top management, [33]. In a study in Morocco, the participants interviewed by Farissi et al [36] identified the main inhibiting factors and attributed 80% of them to a lack of managerial commitment.

The conclusions from the literature reviewed concerning factors that affect the implementation of LM in various countries were conducted to assess and gain in-depth knowledge and understanding of the enabling and inhibiting factors of lean implementation that encourage or discourage LM in the food industry. The identified influential factors across borders include:

Company Culture	Leadership	Skills and Training	Company Structure
Resources	Employee Engagement	Compensation/ Rewards	Change Management

Plant, product, and process in the food industry are contextual factors to be considered in the implementation of lean. The context of the food industry is built around very dissimilar groupings of products with diverse degrees of perishability and various manufacturing lead times; thus, manufacturers must constantly balance the risk of waste versus reduced product quality, risking stock-outs and disgruntled customers [14].

It can be concluded that Skills and Training, Stakeholder Relations, Employee engagement, Change Management, Leadership, Employee Performance and employee characteristics diversity have influence on LM. Further, it can be concluded that the participants have a clear understanding of the company's quality mission statement and quality vision statement and used the Fishbone diagram, (a LM tool for problem solving). That the identified factors identified, skills and training, change management, stakeholder relations, employee engagement, employee performance and leadership all have a positive correlation with LM. It can be concluded that an improvement on any of these factors will influence positively the performance of LM at the food flavours manufacturing company.

6 RECOMMENDATIONS

It is therefore recommended that efforts towards improving communication of policies such as the change management. Enhancing communication will improve stakeholder relations, it was observed from the survey that most of the respondents agree that they are in frequent contact with their customers and that they are in frequent contact with their suppliers.

7 MANAGERIAL IMPLICATIONS

These findings give insight to management on the factors affecting LM implementation, based on this insight, it is recommended that managers purposefully engage employees in problem identification and solutions, involve the shopfloor employees in the improvement process as they have first-hand experience. Also, the training program be revised, enhanced, and implemented to improve the knowledge and skill base of the employees.

8 CONCLUSION

To conclude, the research answered the research questions and satisfied the research objectives as well as provided recommendations to management as an input to their LM implementation strategy.

Appendix 1: Survey questionnaire

- **Annexure D: Survey Questionnaire**

Part A: CONSENT FORM

Please Note:

- All responses to the survey are confidential.
- No names will be link to any data.
- All data collected are strictly for research purposes only.

1) * Please indicate your willingness to participate in this research study, by indicating your preference below:

I am willing to participate

I am not willing to participate

Part B: GENERAL INFORMATION

Please note we collect the demographical data for research purposes only.

2) * Your Gender

Male

Female

Prefer not to say

3) * Your Age Category

18-25 years

26-30 years

31-40 years

41-50 years

51-60 years

61 years or above

4) * What is your employment position in the company?

Senior Management

Middle management

Junior Management (supervisory)

Operational

Support Staff

5) * Number of years serving in the CURRENT position

0 to 5 years

6 to 10 years

11 to 15 years

16 to 20 years

21 years or more

6) * What is your highest academic qualification?

Grade 12 or less

Undergraduate

Diploma/Degree

Master's degree or equivalent or more

7) * During the last 3 month, how do you rate your overall job satisfaction?
Very low 2 3 4 5 Very High

SECTION C: LEAN CULTURE

The purpose of lean manufacturing is to eliminate waste and enhance the value of products produced thereby increasing the company's competitiveness. An example of waste is any form of Re-Work, it can be corrected by doing this right the first time.

- *Transportation - the unwarranted transport of components under production.*
- *Inventory - Heaps of components waiting to be completed or finished goods waiting to be shipped.*
- *Motion – the unwarranted movement of people working on products.*
- *Waiting – the unwarranted waiting by people to begin the next step.*
- *Over-Processing the product with extra steps.*
- *Over-production of products not needed.*
- *Defects in the product.*
- *Under-utilised people*

8) * To what extent do you agree with the following statements when considering your company?

Lean Manufacturing	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
I understand the concept of lean management.					
I am aware of this lean practice, in our company					
Our company is currently implementing lean manufacturing practices					
Our company has been implementing many of the lean manufacturing practices even though we do not call it lean					
Our company is currently implementing HACCP					
Our company is currently implementing FSSC 22000					
Our company is currently implementing NFS					
Our company is currently implementing ISO 9001: 2015					
Our company is currently implementing ISO 45000					

9) * Based on the following table, which of the following has been implemented?

	Not intended to be used / unknown	Planned for use in subsequent year	Planned for use in 3 years	Already in use
Quality vision statement				
Quality mission statement				
Value Stream Mapping				
Takt Time				
Pull system				
Just in time				
Kanban system				
Standard work				
Standardised work sheet				
Levelling production and schedules (heijunka)				
Single minute exchange of die (change overs)				
Error Proofing (poka yoke)				
Visual Management				
Notification system for quality and process problems (Andon)				
Root Cause Analysis (Fishbone diagram)				
5 – why analysis				
Plan-do-check-act PDCA cycle				
5S - method				
Gemba				

Please indicate your level of agreement with the following statements.					
10) *My colleagues have adequate knowledge of Lean Manufacturing	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
11) *Do you think your employee training program on Lean Manufacturing is working?	Not really	Not quite enough	Reasonable training program	Enough training programs	More than enough training program

12) *You are involved in problem identification & improvement of processes (be they Production; innovation; sales; procurement etc) of the company?	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
13) *To what extent can the worker involvement in Lean Manufacturing (waste elimination) programs in your workplace be explained?	Very Poor	Poor	Fair	Good	Very Good
14) * Do you think the opinions and suggestions of employees are given due consideration?	Not at all. Supervisors and managers do not care about employees' opinions.	Sometimes Supervisors and managers listen to their subordinates' opinions.	Supervisors and managers in many cases listen to opinions of employees.	Supervisors and managers always listen to opinions of employees from some employees.	Supervisors and managers always listen to opinions of employees from all levels, and they are responsive.

15) * To what extent do you agree with the following statements regarding the use of Lean Manufacturing practices when considering your company.

Customer Relations	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
We are in frequent contact with our customers.					
Our customers give us feedback on quality and delivery performance.					
We conduct customer satisfaction surveys regularly.					
Supplier Relations					
We are in frequent contact with our Suppliers.					
Our key suppliers deliver to our factory on just-in-time basis.					

We take steps to reduce the number of suppliers in each category to reduce raw material variations.					
Our purchasing / supply function is centralised.					
Internal Operations					
We use the pull production system.					
We use Kanban, squares, or containers of signals for production control.					
Production at station is pulled by the current demand of the next station.					
Products are classified into groups with similar routing requirements.					
Product families determine our factory lay out.					
We are working to lower set up times in our plant from one batch to the next.					
We monitor our production cycle time to respond quickly to customer requests.					
Our employees practice setups to reduce required time.					
Our processes on the shop floor are currently under Statistical Process Control.					
We use charts to show defect rates on the shopfloor.					
Employee Involvement					
Shopfloor employees undergo cross-functional training.					
Shopfloor employees are crucial to problem-solving teams.					
Shopfloor employees lead product/process improvement efforts.					
I welcome change most of the time when it is clearly communicated.					

16) * To what extent do you agree with the following statements regarding the use of Lean Manufacturing practices when considering your company.

Leadership/ Management	**Strongly Disagree**	**Disagree**	**Neutral**	**Agree**	**Strongly Agree**
I have a positive working relationship with my line manager.					
My job allows me to advance my career.					
My manager is aware of my work problems and obstacles.					
Management behaviour in our company is related to subordinate satisfaction and task commitment.					
Management behaviour in our company is related to employee motivation.					
Managers enable the generation of new knowledge and ideas through the use of academic motivation.					
Management enhances employee competence and encourages transformation.					
Managers in the company build exceptional teams and influence performance.					
Employees feel trust, admiration, loyalty and respect toward their manager.					
The company actively promotes a culture of empowerment and motivation.					
Change Management					
Our company has a management of change policy which I am aware of.					
Our company communicates change to employee at the beginning (outset) of the journey.					
Our company communicates change effectively so that all employees affected understand.					
Our company provides training for the change where necessary.					
Our company communicates change effectively so that all employees are on board, cooperate and are supportive.					
Our company motivates its employees throughout the change process.					

17) * To what extent do you agree with the following statements:

My Colleagues……

Employee Performance	**Strongly Disagree**	**Disagree**	**Neutral**	**Agree**	**Strongly Agree**
..adequately complete their assigned duties.					
..execute extra effort to fulfil their tasks beyond expectation.					
..always strive to achieve departmental goals.					
..enjoy sharing information and skills with other colleagues.					
..adhere to informal rules to maintain order.					
..enjoy contributing solutions to solve departmental problems.					
..are committed to their work.					
..value interpersonal relationships.					
..welcome feedback to help improve performance					
Organisational Commitment					
A person should always be loyal to the organisation he/she works in					
One of the main reasons for me to continue to work in this company is loyalty and moreover moral obligations					
I can leave my job if I get a better job offer					
Spending most of his/her career in one institution is good for a worker					
It will not be logical to commit myself emotionally to one organisation					
As for my opinion, being loyal to the organisation is important					

IS THE NORMAL DISTRIBUTION FOR DURATION OF ACTIVITIES ADEQUATE FOR ANALYSIS AND SIMULATION OF A CAR WASH FACILITY?

J.K. Visser[1*]
[1]Department of Engineering and Technology Management
University of Pretoria, South Africa
krigevisser51@gmail.com

ABSTRACT

Many vehicle owners use car wash facilities for washing and cleaning of their vehicles. The daily throughput of cars determines the revenue and profit for the car wash owner. A queue of cars waiting to enter the washing bay and a queue of cars waiting to enter the drying bay develop regularly. A simulation model was developed to study the effect of using non-symmetric probability distributions like the lognormal and gamma input distributions on the total time in the facility which determines the daily throughput of vehicles. Actual duration of the washing and drying processes was measured and used as input parameters for a discrete event simulation. Results showed that using right skewed triangular input distributions gives longer washing and drying durations, causing longer total time in the facility and reduction of throughput. Right skewed distributions are recommended as input for simulation of this type of facility.

Keywords: Car wash facility, Monte Carlo simulation, discrete-event simulation, probability distributions

1 INTRODUCTION

1.1 Background

Vehicles are an important part of an industrial economy in most countries worldwide. In December 2022 there were about 12 million vehicles registered with the National Traffic Information System (Natis) of South Africa [1]. In Gauteng alone there were about 4,5 million vehicles registered. About a third of South African households own and drive a car. It is the most popular way of commuting from home to work for many citizens. It is therefore no surprise that car wash businesses are well established in South Africa and all cities and major towns have at least one car wash facility. There are about ten car wash facilities within a 10km radius of the author's residence in Centurion, Gauteng. Washing and cleaning the interior of a car also is a maintenance activity that is required regularly

A washing facility typically comprises a location for washing the car and a location to dry the exterior and vacuum the interior. Other equipment and material include high pressure pumps, water hoses, dryers, vacuum cleaners, soap, polishes, and other chemicals. Electricity, water, and a sewer discharge point are necessities. All car wash facilities require some manual labour, but manual car washes are labour intensive with 10 to 20 washers and cleaners, depending on the size of the business and facility. There are also by-laws of the town council and safety and environmental regulations that must be considered by car wash business owners e.g., soap and chemical used in the washing process should be discharged into the sewer and not the stormwater system [2].

Car wash facilities usually offer different options for its customers. Some only require a quick wash while most customers make use of a 'special offer' that comprises a wash, dry and vacuum. Vehicles that arrive at the wash facility also differ significantly in size and shape. Normal sedans are abundant, but it seems that the SUV's are increasing in number [1]. Other categories include four-by-four vehicles and microbuses and therefore different pricing strategies are available [3].

1.2 Problem Statement

Car wash owners operate the business to ensure a profit at the end of the financial year. The profit is directly proportional to the throughput of cars which is a function of the duration of the wash, dry and vacuum processes or activities. A customer that arrives at the wash facility and finds that the queue of cars is too long might decide to find a different facility or just wait in the queue. A car wash owner could determine which processes are limiting the throughput by observing the operations daily. One option to increase the throughput is to hire more workers to perform the washing or drying processes. Simulation models are popular for studying and analysing complex industrial processes, and facilities. A process and simulation model can be used as a 'what if' tool to study the effect of changes in the inputs on the output performance.

This paper discusses the development of a simulation model for a typical car wash facility and how the model was applied to determine the effect of changing the interarrival rate of cars. The model was also used to study the effect on output of using different probability distributions for the wash and drying steps of the total process. The primary objective of this research study was to analyse a car washing facility by means of Monte Carlo simulation and discrete event simulation and to evaluate outputs for different input distributions. Sub-objectives were:

- To determine the total time distribution i.e., from the moment that the customer joins the queue to the moment that he leaves the premises;
- To determine the difference in total time and waiting time for different distributions e.g., normal, lognormal, triangular, and gamma distributions.

2 THEORY AND LITERATURE

All human endeavour involves uncertainty and scientists and engineers must consider this uncertainty in projects, operations, and maintenance. Uncertainty is modelled by means of probability. The performance of a car wash business involves uncertainty in the duration of the activities or processes. An important parameter is the total time that a vehicle is on the premises, from the time of arrival until exiting. The overall process can be divided into sub-processes and the duration of each process can be modelled by means of probability distributions. The literature review for this study focused on the modelling of a car wash facility, queueing systems, probability distributions, Monte Carlo simulation and discrete event simulation.

2.1 Car wash facilities

Car wash facilities have varying configurations. Some use automatic washing machines (usually rollers) and dryers while others use hand washing, drying, and vacuuming. Some have only one wash bay while others have two wash bays. The number of drying bays varies from about 4 to 10. There is also variation in the type and size of vehicles that arrive at the car wash facility. The time to wash and to dry such vehicles will thus also vary. In this study it was not feasible to collect the washing and drying durations for different car types and sizes due to time constraints. The owner of the car wash business is concerned with the total time that a vehicle is in the system, the total throughput in an hour or day, the maximum number of vehicles in the queue, and the total cost associated with the operations [4].

2.2 Queueing systems and models

Queueing theory dates to the early 20th century. Research and analysis led to the development of mathematical queueing models which are recognised today as the foundation of queueing theory. A simple queueing system is a server system where customers arrive to receive some service and leave when finished. In the context of this paper, the customer is the driver of the vehicle that arrives at the washing facility which has two 'servers' i.e., the wash service and the drying and vacuuming service. If a vehicle arrives at the wash bay and it is busy, it joins the queue. If the wash step cannot keep up with the rate of arrivals, a queue will build up to the maximum space available [5].

Most queueing models accept a steady state situation where the arrival rate and server rate can be accepted as constant and probabilistic behaviour of the arrivals and service duration need not be considered. In practice though this is hardly ever the case and probabilistic models have therefore been developed to deal with the inherent variation in such systems.

2.3 Monte Carlo Simulation (MCS)

Monte Carlo Simulation is a 'static' simulation that uses random sampling of distributions to produce a distribution of outcomes e.g., the total project cost and total duration, total annual cost for a maintenance department, or total duration of a maintenance task. MCS methods have become popular amongst project managers, operations and maintenance managers, and financial managers. The MCS method is well documented and discussed in various textbooks [6], [7], 8]. Various software programmes for performing simulations are available to model uncertainty in the cost or duration of activities. Two well-known software applications that automate the MCS method are @Risk [9] and Crystal Ball [10]. Some add-ins that provide MCS functionality for MS Excel are also available e.g., SimVoi [11] and RiskAmp [12]. Visser and Howes [13] used a MCS to determine the optimal workforce for a company involved in servicing and repairing imaging equipment at medical facilities throughout the Gauteng province. Meyer and Visser [14] used historical data for duration of project phases in mining industry projects to improve estimates for future projects.

2.4 Discrete event simulation (DES)

Banks [15] defined discrete event simulation models as "*a system for which some variable changes only at a discrete set of points in time*". A repairable system could typically be in an operational or running state and when a failure occurs it changes to a stopped state. When a repair or replacement is completed the system changes to a running state again. A DES is useful to model failures and repairs and determine the availability of a system from the failure times and repair times. Two discrete event simulation software programmes, GoldSim [16] and Arena [17], are often used to model a variety of manufacturing processes like cars arriving at a service station for fuel or at a workshop for a service or repairs.

Vàzques-Serrano et al. [18] reviewed 231 papers on the application of DES in healthcare. The study found that the DES was mostly used in emergency departments and medical centres to determine the allocation of resources and to improve duration of processes and efficiency.

Revina and Trifonova [19] used a DES to model the processes in a car service centre. Optimisation with the simulation model identified the bottlenecks in the service centre. Changes were subsequently made to the staff schedule, allocation of workers to work, and the number of posts. The changes led to an increase in the profit of the business by a factor of 1,9.

Greasely [20] described a methodology to implement a DES using a spreadsheet. A case study of a supermarket is used to explain how a spreadsheet can be used to model the system and how to use it in an educational context.

2.5 Probability distributions for modelling duration

Udoumoh and Ebong [21] discussed several probability distributions that are suitable for use in a MC simulation. The normal, lognormal, triangular gamma and Weibull distributions are included in their study. McLaughlin [22] as well as Evans et al. [23] compiled a comprehensive collection of probability distributions and formulas to calculate the density function (PDF), cumulative distribution function (CDF), mean value, and standard deviation.

The normal distribution, also known as the Gaussian distribution, is one of the most popular distributions used in MCS, general engineering, and science. It is a continuous and symmetric distribution with two parameters i.e., the mean value, μ, and the standard deviation σ. The distribution does not perform well when activities are severely right skewed [6]. Random variates for the normal distribution can be calculated with the norminv(rand(); μ; σ) function of Excel, where rand() is the random number generator provided by Excel [23].

The lognormal distribution is a non-symmetric, right-skewed distribution that is useful to model the duration of activities or tasks. Many tasks often take longer than planned since unexpected failures of equipment and tools occur. The distribution has two parameters i.e., the mean value, μ, and the standard deviation σ. Random variates can be calculated using the Excel function lognorm.inv(rand(); μ; σ) [23].

The triangular distribution is bounded on the left and right and can be symmetric, left skewed, or right skewed depending on the values of the three parameters that determine the shape of the distribution [23]. The three parameters of the triangular distribution are typically a (lower bound), m (mode), and b (upper bound) [23]. Forbes et al. [24] provide formulas for calculating the random variates for the triangular distribution.

$$T = \left\{a + \sqrt{\rho(b-a)(m-a)}\right\} \text{ for } 0< \rho <F(m) \quad (1)$$

$$T = \left\{b - \sqrt{(1-\rho)(b-a)(b-m)}\right\} \text{ for } F(m)\leq \rho <1 \quad (2)$$

Where $F(m)$ = (m-a)/(b-a) and ρ is a random number between 0 and 1.

The gamma distribution is skewed and often used in reliability to model failure times of equipment [23]. It has a shape parameter, $k > 0$, and a scale parameter, $\theta > 0$. The density function can have many different shapes depending on the values of the parameters. Random variates can be determined using the Excel function gamma.inv(rand(); k; θ) [23].

The Gumbel distribution is also known as the Extreme Value distribution (Type I) and has a location parameter $\mu > 0$ and a scale parameter $\beta > 0$ [23]. This distribution is mainly used in the analysis of extreme values e.g., flood levels in rivers and earthquake damage. A random variate, T, for the Gumbel distribution was calculated using equation 1 from Forbes et al. [22].

$$T(\rho, \mu, \beta) = \mu - \beta \cdot ln\left[ln\left(\frac{1}{\rho}\right)\right] \qquad (3)$$

where ρ is a random number from 0-1 and β and μ are the parameters of the Gumbel distribution.

The Weibull distribution is used extensively for modelling reliability of assets due to its versatility regarding the failure rate. It has two parameters i.e., a shape parameter, β, and a 'characteristic life' parameter, η [23]. The Weibull distribution is also useful to model task or activity duration since it is one of a few distributions that is skewed towards the left (negative skewness) for some values of the parameters. It is therefore not suitable for right-skewed activities [4]. A random variate, T, for the Weibull distribution was calculated using equation 2 [see 24].

$$T(\rho, \beta, \eta) = \eta \cdot \left[ln\left(1 - \frac{1}{1-\rho}\right)\right]^{\frac{1}{\beta}} \qquad (4)$$

where ρ is a random number, β is the shape parameter and η the characteristic life parameter of the Weibull distribution.

2.6 Comparison of probability distributions

Ferson et al. [25] said "*the results of probabilistic risk analyses are known to be sensitive to the choice of distributions used as inputs, an effect which is undoubtedly even stronger for the tail probabilities*". Some probability distributions are called fat-tailed which can be defined as a distribution that exhibits a large skewness or kurtosis. The occurrence of very large random variates is more likely for fat-tailed distributions like the lognormal, gamma, and Gumbel distributions than for the normal distribution.

Hajdu and Bokor [26] performed MC simulations with uniform, triangular and beta distributions and noted: "*the use of different distributions with the same three-point estimation has a smaller effect on the project duration than a 10% difference in the values of the three-point estimation*". Visser [27] found that the output distribution of a simulation depends on the complexity of the system being modelled, the distribution selected for the inputs, and the values for the parameters of the distribution selected. Wood [28] said: using the same input data as the mean and variance values, the output distributions for the normal, lognormal, and triangular distributions could vary by as much as 10%. This contradicts the findings of Hajdu and Bokor [26].

Balasooriya and Abeysinghe [29] compared the results of a simulation with the gamma and Weibull distributions using the same data set. They found that even though distribution fitting produced similar goodness of fit values, it was important to choose the best distribution for analysis and simulation purposes. Kundu and Manglick [30] said: "*The lognormal and Weibull distributions are the most popular distributions for modelling skewed data*". They developed a method to select between the gamma or lognormal distribution when failure data are available. The ratio of maximum likelihood was used to determine the better of the two distributions. Alzaid and Sultan [31] studied the problem of fitting given data to a gamma or lognormal distribution and selecting the better of these two distributions. They found that the gamma distribution gave a better fit than the lognormal in many situations. The method was tested with an actual data set. Monte Carlo simulation with 10000 trials was used to determine goodness of fit.

3 MODEL FOR VEHICLE WASHING FACILITY

The steps in the overall car wash process were observed visually and a block flow diagram or process map of the washing facility used for this case study is shown in Figure 1.

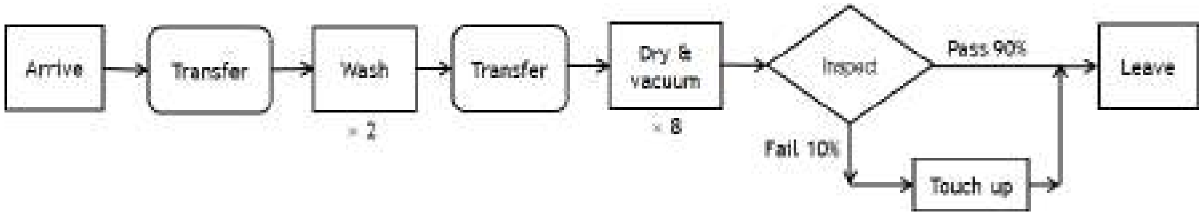

Figure 1. Block diagram for vehicle washing facility

Upon arrival at the facility, a vehicle joins the queue if both washing bays are occupied. As soon as one of the wash bays is open, the vehicle in the front moves from the waiting area into the wash bay where the washing activity is started. The time to transfer to the wash bay was measured 5 times and a minimum and maximum value of 12-15 seconds were allocated for this duration. The mean time and standard deviation for the wash process was obtained from actual data. When the wash step is finished, the vehicle proceeds to any of the drying bays that is available. If not, the car must wait until a bay is open. This transfer time was also observed 5 times and minimum and maximum values of 18-24 seconds were allocated for this duration. The mean duration and standard deviation for the drying process was obtained from actual data. When the drying stage is finished, a supervisor performs a brief inspection of the quality of work. The duration of this activity was measured 10 times and an average duration of 40 seconds was used as a constant in the simulation. If the quality check is positive, the vehicle leaves the premises. If negative, the supervisor or other worker performs a touch-up and the vehicle leaves. The duration of the touch up activity was measured, and an average value of 30 seconds was used as a constant in the simulation.

4 RESEARCH METHODOLOGY

4.1 Time data for vehicles

This project involved a case study of one car washing facility. The first step in the study was to obtain primary data for the duration of the wash and the drying/vacuuming steps of the process. Some 31 duration values were measured for the drying step and 16 duration values were measured for the washing step on three days of observation. The days chosen were days that the washing facility is very busy i.e., on Saturdays and Friday mornings. Descriptive statistics were calculated for this data to obtain the mean time and standard deviation for the wash and drying steps.

Six probability distributions i.e., normal, lognormal, gamma, Gumbel, Weibull, and triangular distributions, were fitted to the duration data of the drying process. The duration data was ranked from lowest to highest and a rank number, i, was assigned to each value. Breneman et al. [32] proposes a predictor for the cumulative distribution as the ratio of the rank number and the total number of data points as shown in equation 3.

$$F(i) = \frac{i}{N} \tag{5}$$

Guess values for the parameters of each distribution, based on the mean and standard deviation values as calculated with Excel AVERAGE and STDEV.P functions, were assumed and 31 values of the cumulative distribution was calculated using the formula for the cumulative distribution function in Excel i.e., norm.dist(i; μ; σ; true). The difference between the F(i) and the density function was squared and added for all 31 points. The Excel Solver add-in was used to vary the values of μ and σ until the minimum value for the sum of the squares for all data points is achieved. This process was repeated for all six distributions.

4.2 Performing a Monte Carlo Simulation in Excel

A mean value of 5,75min for the wash process and 18min for the drying process was used for the normal distribution. Standard deviation values of 1,0min for the wash process and 3,0min for the drying process were used. The total time for a car in the system was calculated by adding the distributions for all processes. The inverse variates for the distributions were then calculated for 50000 trials or repetitions. Usually about 10000 trials are adequate but 50000 was used in this case study to ensure credible results. The mean value, standard deviation and skewness values for these trials were calculated using standard Excel functions. Parameters for the lognormal, triangular, gamma and Gumbel distributions were calculated from the mean and standard deviations mentioned earlier.

4.3 Performing a Discrete Event Simulation

Estay [33] describe a process to perform a discrete-event simulation (DES) using a spreadsheet. It was applied to a simple system with two processes in a healthcare scenario. Elizandro and Taha [34] developed a discrete event simulation for an industrial system with Excel and visual basic. Quintão et al. [35] discuss the results of a discrete event simulation for a car wash facility using Arena software. Analysis of actual data indicated that queue congestion and long waiting times occur. The simulation minimised the queue length and reduced the waiting time by optimising the resources of the system.

The car wash facility used in this case study has two processes. The first column in the spreadsheet indicates the numbers of the cars that arrive over a period of 4 hours, for example 50 cars. The next column could indicate the inter-arrival times for the 50 cars as determined from the inverse of the exponential distribution. Further columns in the worksheet are needed for the wash time calculated from the inverse of the distribution and the drying time from the inverse of the drying time distribution. The arrival times for each car is noted in a separate column, the first car can be advanced to the wash bay, and the start time for this car is noted in a separate column. The finish time for the car is the start time for the wash plus the duration of the wash. There should be two columns for the two parallel wash bays and 8 columns for the 8 parallel wash bays. The simulation can be automated to increase the speed of processing by using specialist software available from several software developers.

5 RESULTS

5.1 Primary data

Sixteen duration values were captured for the washing operation and 31 duration values for the drying process. The actual data for the wash and drying processes is shown in Table 1.

Table 1: Duration data for wash and drying activities

Number	Dry (min)	Wash (min)
1	15,0	2,084
2	17,0	3,000
3	18,0	3,167
4	17,0	2,917
5	22,0	2,250
6	17,0	2,667
7	20,0	2,500
8	19,0	3,000
9	20,0	3,250
10	23,0	2,834
11	15,0	2,500
12	13,0	4,000
13	19,0	3,834
14	15,0	2,750
15	18,0	2,750
16	15,0	2,500
17	18,0	
18	16,0	
19	21,0	
20	18,0	
21	22,0	
22	23,0	
23	15,0	
24	19,0	
25	15,0	
26	23,0	
27	17,0	
28	21,0	
29	14,0	
30	17,0	
31	14,0	
Mean	17,936	5,750
Std. Dev.	2,920	0,995

The 31 data points for the drying activity were used to fit six probability distributions. The SOLVER add-in for Excel was used to determine the mean, standard deviation, and least squares values for these distributions as shown Table 2.

Table 2: Parameters and least squares values for six distributions

Distribution	Mean (min)	Std. Dev. (min)	Least squares value
Triangular	17,732	3,003	0,0473
Gamma	17,751	3,193	0,0489
Lognormal	17,524	1,198	0,0490
Normal	17,631	3,178	0,0528
Gumbel	18,002	3,525	0,0561
Weibull	17,478	3,260	0,0663

From this data the triangular distribution provides the best fit and the Weibull distribution the worst fit for the drying process. However, the least square values do not differ much and any of these six distributions could be used in a simulation to model the drying activity duration. The mean value of 17,936 minutes (Table 1) for drying was rounded to 18 minutes and the standard deviation of 2,92 was rounded to 3,0 minutes. The mean value of 5,75 minutes for drying was taken and the standard deviation of 0,995 minutes was rounded to 1,0 minutes. The minimum and maximum values for the two transfer times, inspection time and touch-up duration were selected based on the duration measured for 5 cars. The following values in Table 3 were used for the MCS and the DES.

Table 3: Input values used for MCS and DES simulations

Activity/process	Distribution	Parameter 1	Parameter 2
Transfer 1 (s)	Uniform	18	24
Washing (min)	Normal	5,75	1,0
Transfer 2 (s)	Uniform	12	15
Drying (min)	Normal	18,0	3,0
Inspection (s)	Constant	30	-
Touch up (s)	Uniform	30	40

For the lognormal, triangular and gamma distributions, the parameters in Table 3 for the washing and drying processes were calculated from the mean and standard deviation values of the normal distribution. The other durations remained the same.

5.2 Results of Monte Carlo Simulation

The total time for a car to move from the queue to the final process and leave the facility was modelled using a Monte Carlo simulation in Excel. The inverse cumulative distributions were used to calculate the variates for five probability distributions. Inverse distribution functions are available in Excel for the normal (norm.inv), lognormal (lognorm.inv) and gamma (gamma.inv) distributions. Equation 3 was used to calculate the inverse for the Gumbel distribution and equation 4 was used for the inverse of the Weibull distribution. The inverse function for the triangular distribution is available from Breneman et al. [31].

The output of the MC simulation is a histogram of the probability density function for the total time that the car takes from the moment that it enters the wash bay until it leaves the facility. Some parameters for the total time distribution like the mean, standard deviation and skewness are calculated in Excel. The 90% (P90) and 95% (P95) probabilities are also shown in the summary of the relevant parameters in Table 4.

Table 4: Summary output of Monte Carlo simulation in Excel

Parameter	Normal	Lognormal	Triangular	Gamma	Gumbel
Mean (min)	24,820	24,826	24,847	24,818	24,834
Std Dev. (min)	3,170	3,156	3,171	3,159	3,179
Skewness	+0,020	+0,436	+0,327	+0,284	+1,051
P90 (min)	28,905	28,954	29,350	28,914	28,983
P95 (min)	30,078	30,383	30,473	30,254	30,722

The mean and standard deviation values do not differ significantly since the same values were used for all five simulations with different distributions. The skewness varies from 0,020 for the normal distribution to 1,051 for the Gumbel distribution. All the distributions for the total time are right-skewed. The P95 values differ from 30,078 for the normal distribution to 30,722 for the Gumbel distribution. The differences in P90 and P95 values are not significant, and it can therefore be concluded that for a MCS of the total time for this car wash facility, the normal distribution would be adequate. A data analyst who wants to run a MCS for some other washing facility should obtain some data points for the washing and drying processes, calculate the mean and standard deviations, and use these values and a normal distribution.

5.3 Results of Discrete Event Simulation

The same values for the mean duration and standard deviation for the washing and the drying processes were used for the discrete event simulation (DES). The distributions for the transfer times and inspection time were also the same. The DES was run for the normal, lognormal, triangular and gamma distributions for the washing and drying processes. The inter-arrival times used were 5,0 minutes, 4,0 minutes, and 3,5 minutes. The main output of the simulation is the total time in the system for 100 trails. The maximum total time in the system, the average waiting time, the maximum waiting time, the average number of cars in the queue waiting to enter the wash bay, and the maximum number of cars in the queue waiting to enter the wash bay were determined. These values are shown in the charts in Figures 2 to 6 below.

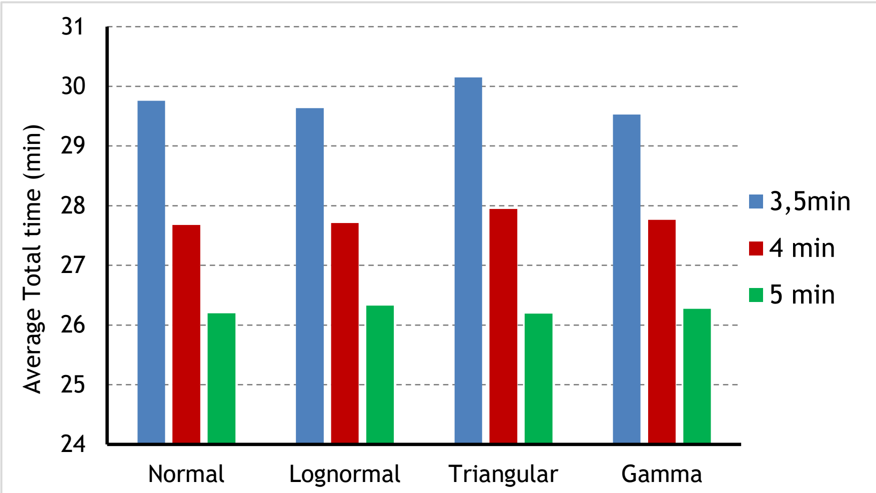

Figure 2: Average total time in facility for different arrival rates

From Figure 2 it is noticed that the average total time for 100 trials increases for all four distributions as the inter-arrival rates decrease, from 26,2 minutes to 29,8 minutes for the normal distribution. The triangular distribution has the longest total time of 30,1 minutes.

The average of the maximum times and 100 trials was calculated and is shown in Figure 3 for the four distributions and three inter-arrival times.

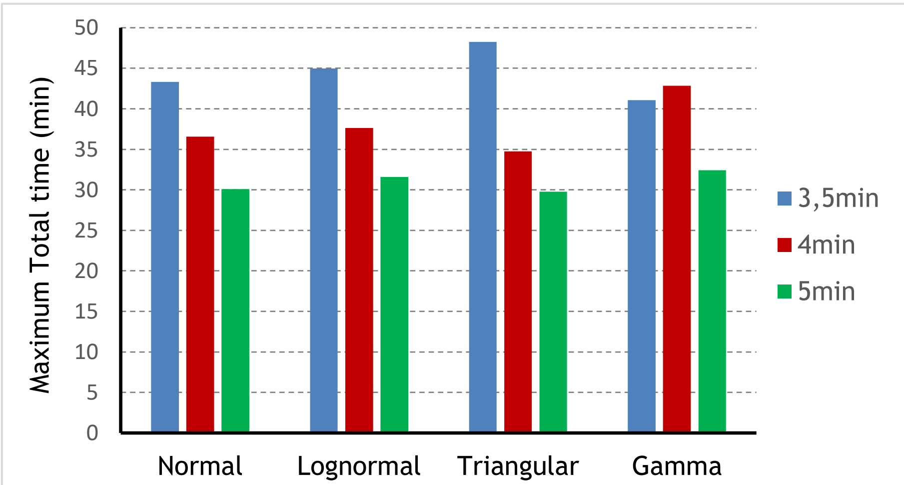

Figure 3: Average of maximum time in washing facility for 100 trials

The average maximum time in the system varies from 30,1 to 43,3 minutes for the normal distribution, and from 29,8 to 48,2 minutes for the triangular distribution. The tail of the skewed distributions produces longer durations for the wash and drying processes than that of the normal distribution. In practice, using a normal distribution in DES will underestimate the total time in the system.

The largest total waiting time for the cars in 100 trials is shown in Figure 4. The maximum waiting time increases as the arrival rate increases, which is to be expected. For an inter-arrival time of 3,5 minutes, the maximum waiting time increase from 18,3min for the normal distribution to 23,3 minutes for the triangular distribution. This represents a 25% increase.

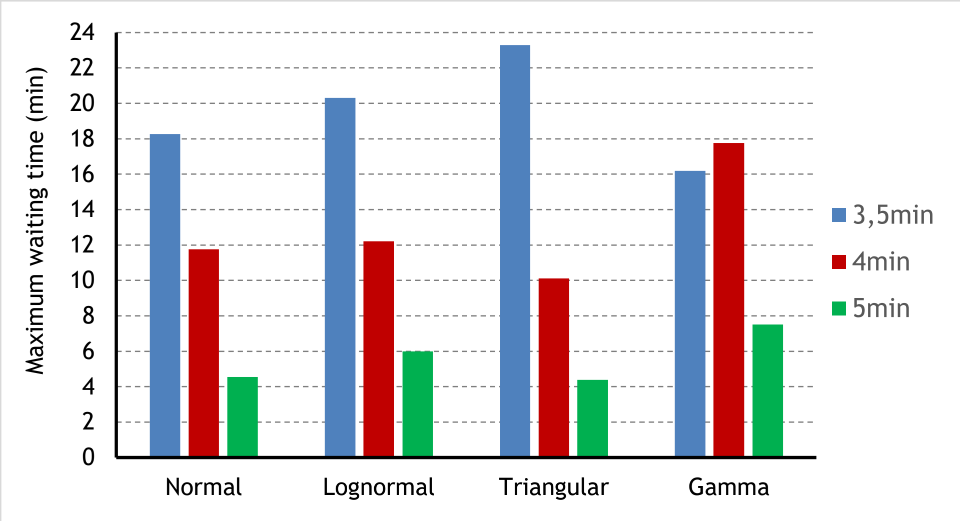

Figure 4: Maximum waiting time in 100 trials for different arrival rates

The maximum number of cars waiting in the queue to enter the process is shown in Figure 5 for three arrival rates and four distributions. For an inter-arrival time of 5 minutes (12 cars per hour) the normal, lognormal, and triangular distributions have a largest queue of just over 1 car. However, for an inter-arrival time of 3,5 min (about 17 cars/hour) the number of cars in the queue to enter the wash bay increases to 8,6 for the normal distribution and 10,4 for the triangular distribution.

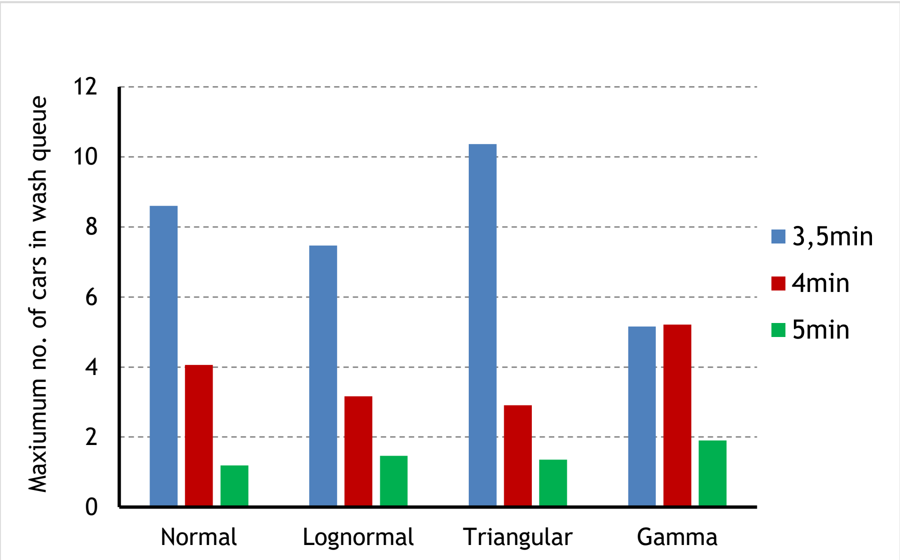

Figure 5: Maximum number of cars waiting in the queue for the wash process

The maximum number of cars that can be accommodated in the queue is 10, therefore some customers might pass and come back later or look for some other washing facility close-by.

5.4 Summary of findings

The distribution fitting indicated that the triangular distribution had the best fit and the gamma distribution the second best fit for the measured data. The MCS showed a slight increase in the total time that the vehicle is in the system as measured by the P90 and P95 values for the triangular distribution compared to the values for the normal distribution, but this total time excluded the waiting time. For the DES, it was observed that the total time that a vehicle spends in the system increases as the inter-arrival time decreases. The waiting time for the vehicles also increases as well as the number of cars waiting to enter the wash bay. The total time in the system and the total waiting time for the lognormal, triangular, and gamma distributions is mostly higher than when the normal distribution is used.

6 CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusions

Process duration data was collected for the washing and drying steps of a car wash process. Descriptive statistics indicated mean and standard deviation values for the wash process for the drying process. The skewness of 0,27 for the drying process indicated that the data is not normally distributed. A curve fit using the least squares method showed that the triangular distribution has the best fit for the data and the Weibull distribution has the worst fit. A MC simulation for the process using different distributions for the wash and drying steps showed only small differences in the P90 and P95 values for the cumulative distribution for the total duration of the car in the washing facility.

The same values for the average and standard deviation for the wash and the drying step of the car wash system that were used for the MC simulation were used for a discrete event simulation (DES). Values were determined for the average time that a customer spends in the system from the moment that he/she joins the queue until he/she leaves the premises. The total waiting time was also determined for three values of the interarrival time of cars that arrive at the car wash facility.

The main objective of the study was to analyse the car wash system by means of a Monte Carlo simulation and a discrete event simulation. The sub-objectives were to determine the total time that a vehicle spends in the system, the waiting time in the queue, and the number of vehicles in the queue. The main and sub-objectives were achieved, and the DES showed that the normal distribution might not be adequate for this car wash system since it underestimates the maximum total time in the system, the maximum waiting time in the queue, and the maximum number of vehicles in the queue. A right-skewed distribution more accurately predicts the output parameters.

6.2 Recommendations

The following improvements are suggested for a more realistic model and simulation experiment for a car was facility:

- Obtain more duration data for the wash and the drying steps of the process. A hundred data values will lead to more accurate values for the mean and standard deviation values of both processes.
- The current policy is to direct cars from the wash bays to drying bays sequentially. The model in this paper just directs a car from the wash bay to any open drying bay randomly. The model could be modified to direct cars sequentially.
- A third wash bay and a ninth drying bay could be added to the facility. This will ease the pressure on the work teams when the arrival rate of cars increases. It would require additional workers and an increase in the cost; therefore, a cost-benefit analysis should be done before such an addition is implemented.

ABSTRACT

South Africa hosts some of the deepest and most complex mines in the world. Consequently, effective ventilation of underground areas is challenging. The expansion of deep-level mines offers additional hazards in the ventilation system that need to be managed proactively. Hazards include high temperatures, dust pick-up and gas build-up. Currently, most gold mines in South Africa are nearing the end of their planned life-of-mine (LOM). This means that new deepening projects must be implemented to extend the LOM. This study presents a comparison between incremental and end-state planning with the use of a calibrated digital twin. The main contribution of this study is indicating the effect of incremental planning when planning the installation of important infrastructure. This emphasises the importance of effective planning methods to ensure the success of the overall future of the mine.

Keywords: Deep-level mine; Digital twin; Ventilation; Hazard identification; Hazard mitigation

1 INTRODUCTION

South Africa has the largest reserves of platinum-group metals (PGMs), manganese, chromite and gold [1]. South Africa also houses six of the top ten deepest mines in the world [2]. The extreme depths of these mines are mostly due to the depletion of the original ore reserve [1]. These mines expanded deep into the earth and are now reaching the end of their life-of-mine (LOM). Figure 1 illustrates the current LOM and depth of all the major gold- and PGM mines in South Africa in 2023.

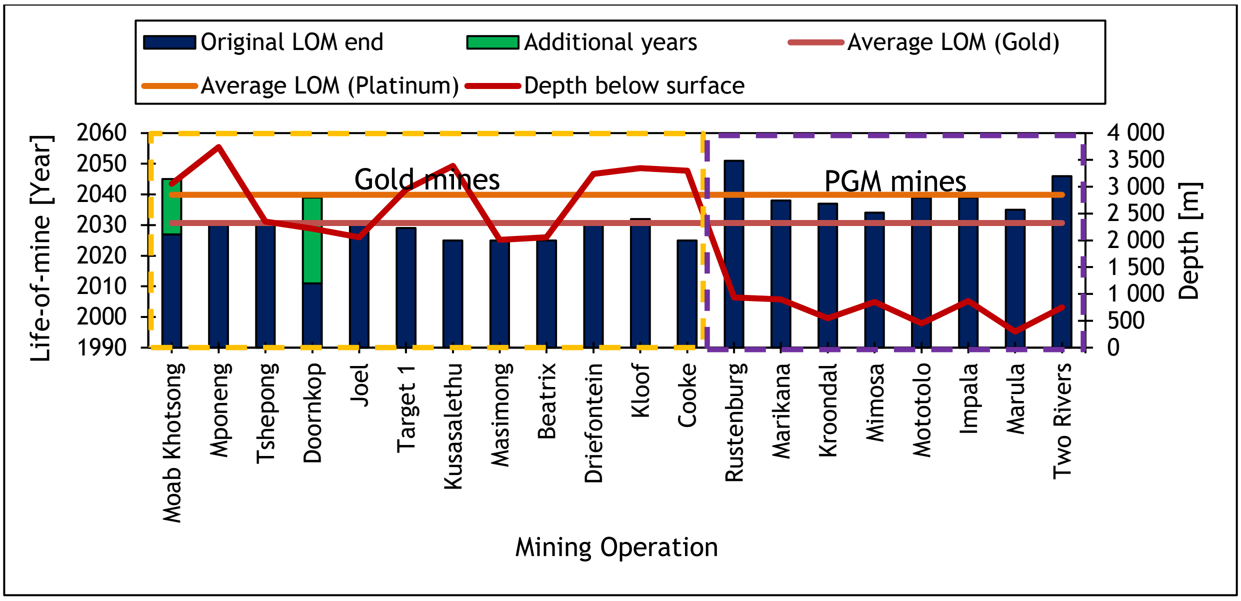

Figure 1: LOM and depth of major gold- and PGM mines in South Africa [3-5].

Figure 1 shows that most of the gold mines are nearing their end of life by 2030 and are reaching depths over two kilometres deep [3-5]. The PGM mines have a longer LOM and are much shallower than gold mines with most not even reaching one kilometre in depth [5]. Figure 1 also shows that the LOM of some of the mines were extended [3] by deepening projects which were not part of the original LOM plan [3].

One of the main challenges with further deepening of these mines is the planning of the ventilation system [6] [7]. The ventilation system is the primary means of cooling the mine and providing a sustainable working environment. It becomes more and more challenging to ventilate and cool deep-level mines due to the increase in virgin rock temperature (VRT) [6]. Figure 2 illustrates the increase in VRT as the depth below surface increases, for the Witwatersrand, Klerksdorp, Free state, Bushveld complex and Plats reef regions.

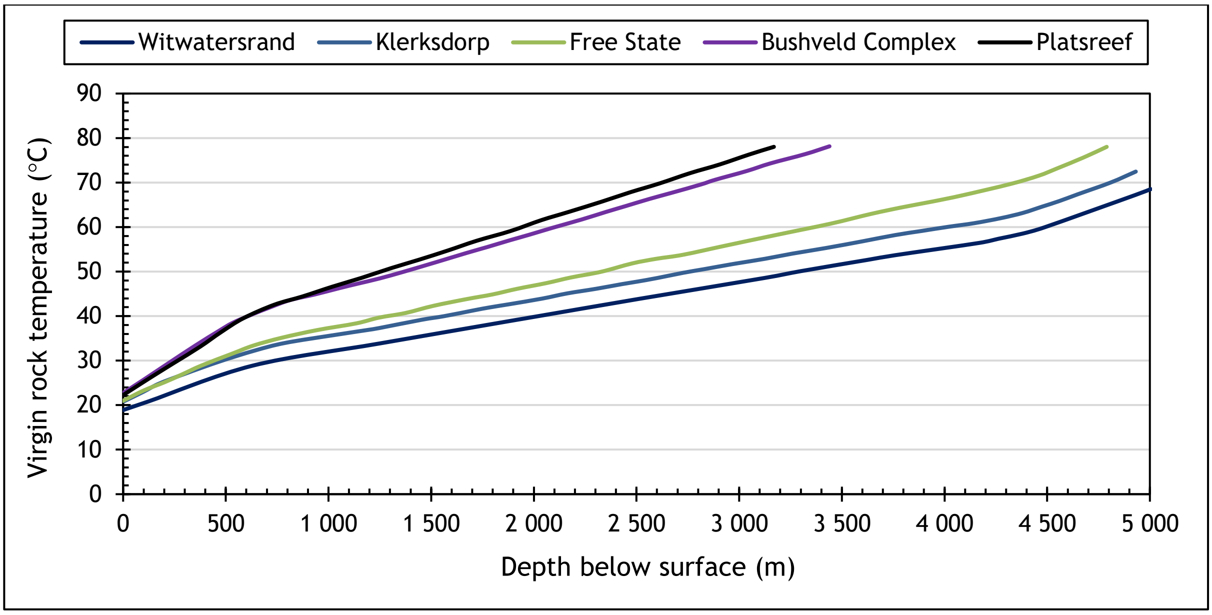

Figure 2: VRT increase as depth below surface increases [6]

The increase in depth below surface of South African gold mines increases the risk of heat exposure to underground workers making it imperative that heat be mitigated effectively [6-9]. The health and safety of underground workers should always take priority. There have been various studies which illustrated the properties and guidelines for a safe working environment [7] [8] [10-14].

These studies indicated three major hazards that can occur in ventilation systems, namely high temperature, gas build-up, and dust pollutants in the air [7] [8] [10-14]. These hazards can cause various illnesses that can prove fatal to underground workers [8] [15] [16]. There are various mitigation tactics that have been deployed which mainly entail detection and control [17-19]. These tactics are reactive and not preventative but will always remain necessary due to the occurrence of unforeseen events.

There are other tools that can be used to help prevent hazards occurring in ventilation systems. Tools such as digital twins which can be defined as cyber-physical copies of actual system can be used to simulate an actual system [20]. Digital twins have been utilised in many instances to help plan and improve various deep-level mining systems including ventilation [20-23], refrigeration [24], and compressed air [25].

Therefore, digital twins can be used in effective planning to avoid these hazards entirely. This study will compare two planning methods, namely incremental- and end-state planning [26-29]. Incremental planning is when a system is planned in set increments as a system is developed. This ensures that the system will operate as required during each stage of development. The end-state planning method entails the planning of the system when it is fully developed and ensures that the system will operate as required when fully developed.

2 PROBLEM AND OBJECTIVES

The incremental and end- state planning methods have been used in various studies to plan ventilation systems [26-29]. There are, however, limitations to each of these methods. The problem therefore exists to know when each of these methods should be used and what results to expect when mitigating hazards. There is, however, no clear distinction found in literature to aid in choosing the correct method for a given scenario.

Consequently, the objective of this paper is to apply both methods on the planning of a deep-level case study mine ventilation system for comparison to aid future mine ventilation system expansion projects in South Africa.

3 METHOD FOR IDENTIFYING VENTILATION HAZARDS

This study will utilise the hazard identification and mitigation method previously developed [9] and summarised in Figure 3.

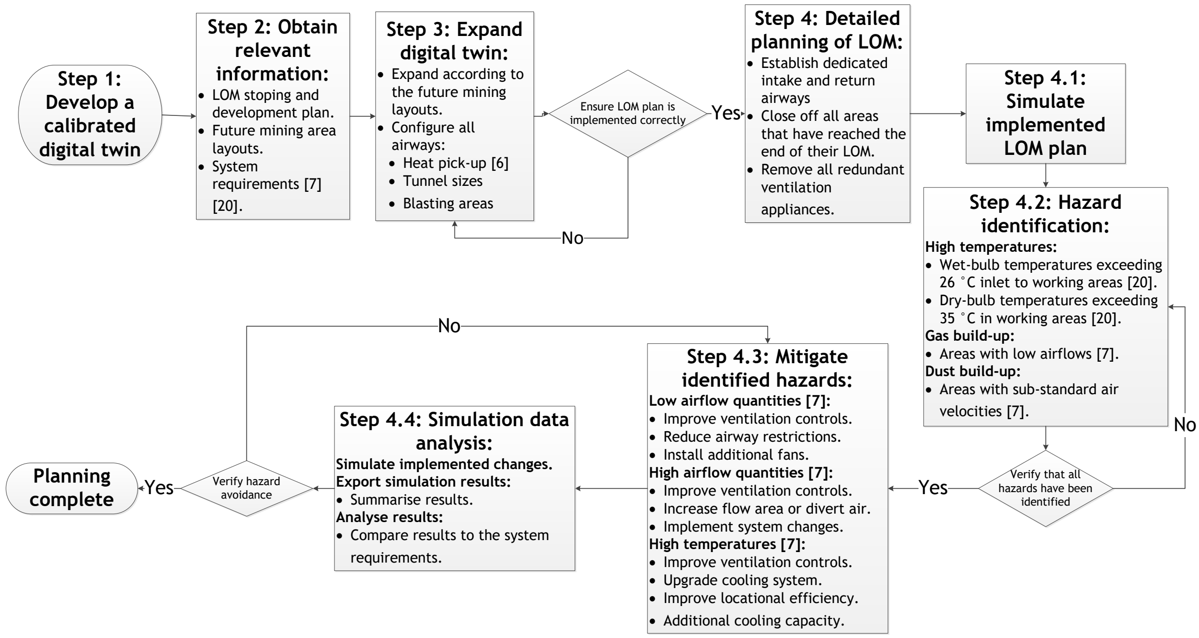

Figure 3: Summary of the mine ventilation hazard identification and mitigation method previously developed [9]

Figure 3 shows what steps are taken to effectively identify and mitigate hazards. The strategy was described in more detail in a previous study. The objective of this study is how this strategy can be used in incremental and end-state planning methods. Figure 3 does not mention the incremental- and end-state methods. This method can, however, be utilised for both planning methods as follow:

- Incremental planning:
    - o Evaluate LOM plan to effectively divide the system development into increments.
    - o Expand the digital twin in Step 3 (Figure 3) to represent the mine for each of the increments.
    - o Complete the method in Figure 3 for each of these increments.
- End-state planning:
    - o Expand the mine to the point in the LOM where it is fully developed.
    - o Complete the method in Figure 3 on the fully developed mine.

The results section of this paper illustrates how the strategy is utilised in both methods and what information was gathered and displayed. The results obtained from these two methods was then used to see which of the two planning methods are most effective in deep-level mine ventilation LOM planning. This is the main objective and contribution of this study.

4 RESULTS & DISCUSSION

Figure 3 illustrates the strategy which was applied to a case study mine. This section will describe each step and how it was applied in both the incremental and end-state planning methods. The results of both planning methods will also be compared during each step before being summarised in the discussion section to validate that the main objective of this study has been achieved.

Step 1: Develop a calibrated digital twin

The first step, according to Figure 3, is to develop a calibrated digital twin. This digital twin is used as a base model to which the future expansions of the mine will be added later. This means that this step will be identical for both incremental and end-state planning methods.

The digital twin that is developed and calibrated for this study by using the method previously developed by Jacobs (2020) with the use of Process toolbox (PTB) [20]. Figure 4 illustrates the calibrated ventilation digital twin of the mine evaluated in this paper.

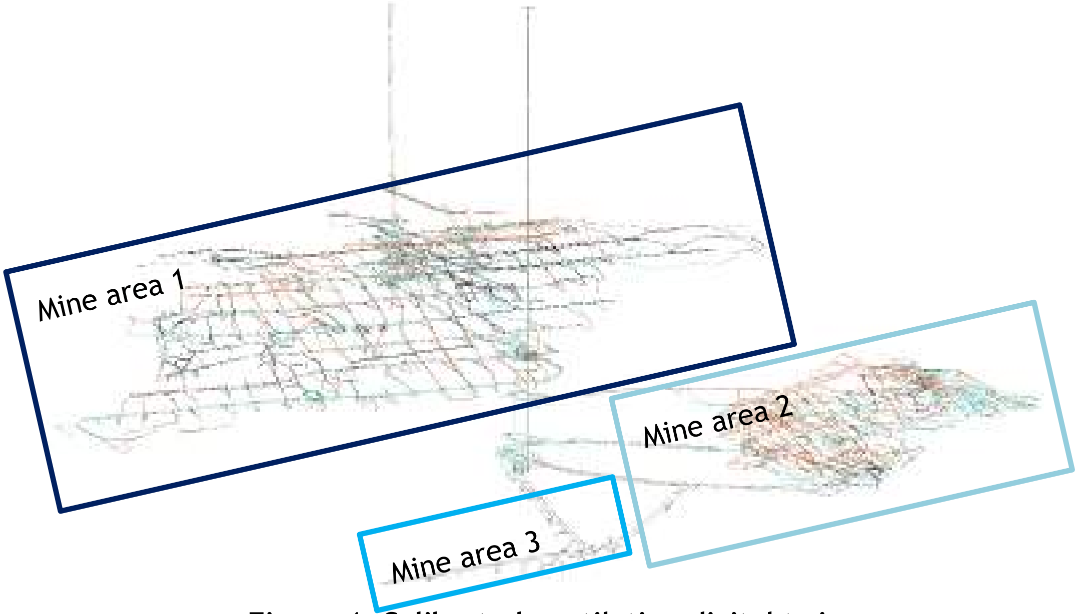

Figure 4: Calibrated ventilation digital twin

The calibration, for the purpose of this paper, can be summarised by evaluating:

- The average surface and underground booster fan pressures and total flows – 98% accurate.
- The average station flow and temperatures – 92% accurate.
- The average working area inlet temperatures and flow – 97% accurate.

This yielded an overall accuracy of 96% when compared to the performance of the actual ventilation system. The current actual system and its digital twin exhibit identical responses and can therefore be utilised to predict the performance of the system as the mine expands and develops.

Step 2: Obtain relevant information

The information obtained will be utilised for both planning methods. The means by which it is used will however differ as follows:

Step 2.1: The LOM stoping and development plan

The LOM plan includes various information which is used to estimate the planned tonnes of ore extracted at each active area within the mine. Figure 5 illustrates the planned ore to be extracted from the mine evaluated in this study.

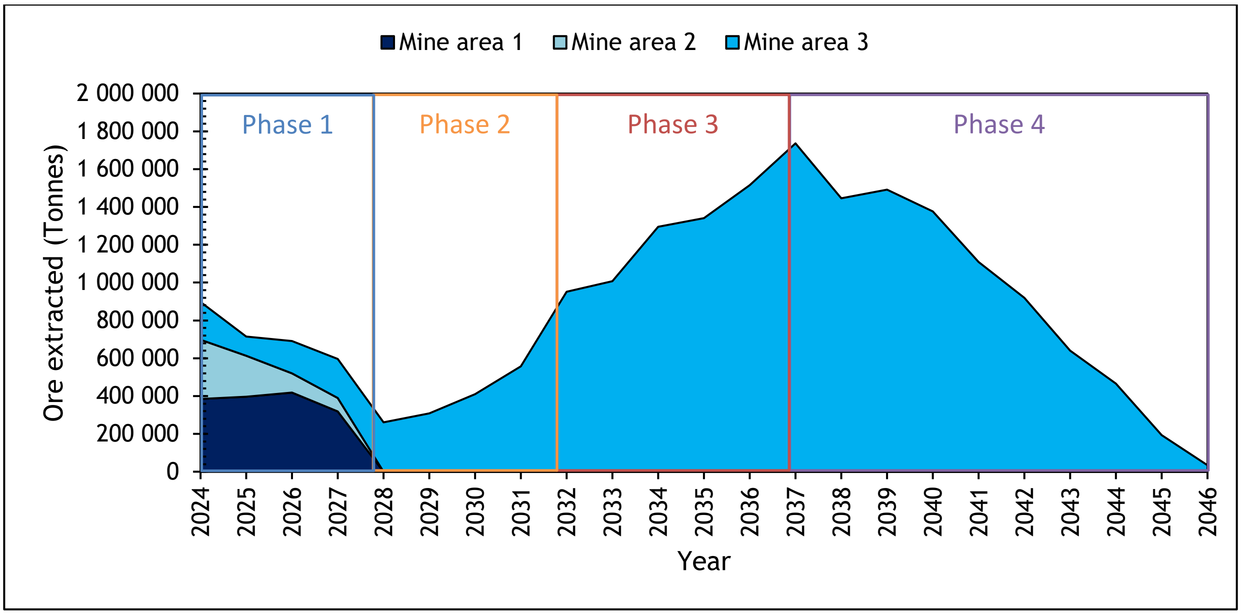

Figure 5: Planned ore extracted during case study's LOM

Figure 5 shows the phases of development of the case study mine evaluated in this paper. Mine areas 1 and 2 will no longer produce gold at the end of phase 1. Mine area 3 is still in the development phase during phase 1 and is the future of the mine. The success of phase 1 determines the overall future of the LOM plan. Therefore, for the purpose of this study, focus will only be placed on phase 1. This information is utilised in both planning methods and the difference between the methods are as follows:

Incremental planning method:

The LOM plan is divided into a chosen increment, based on a variety of factors, such as the scale and complexity of the mine plan, the mining method, and the level of detail required [27] [30]. The smaller the increment, the more detail can be added to the ventilation plan. As noted by Mamghaderi (2021), smaller increments could also increase the complexity and cost of the mine design [26]. Therefore, larger increments may be simpler and more efficient, but some detail to the plan will be sacrificed.

This study will utilise 6-month increments since the LOM plan is divide into years and 6 months will ensure that two instances of each year is planned. Figure 6 illustrates the planned ore extracted during phase 1, distributed into 6-month increments.

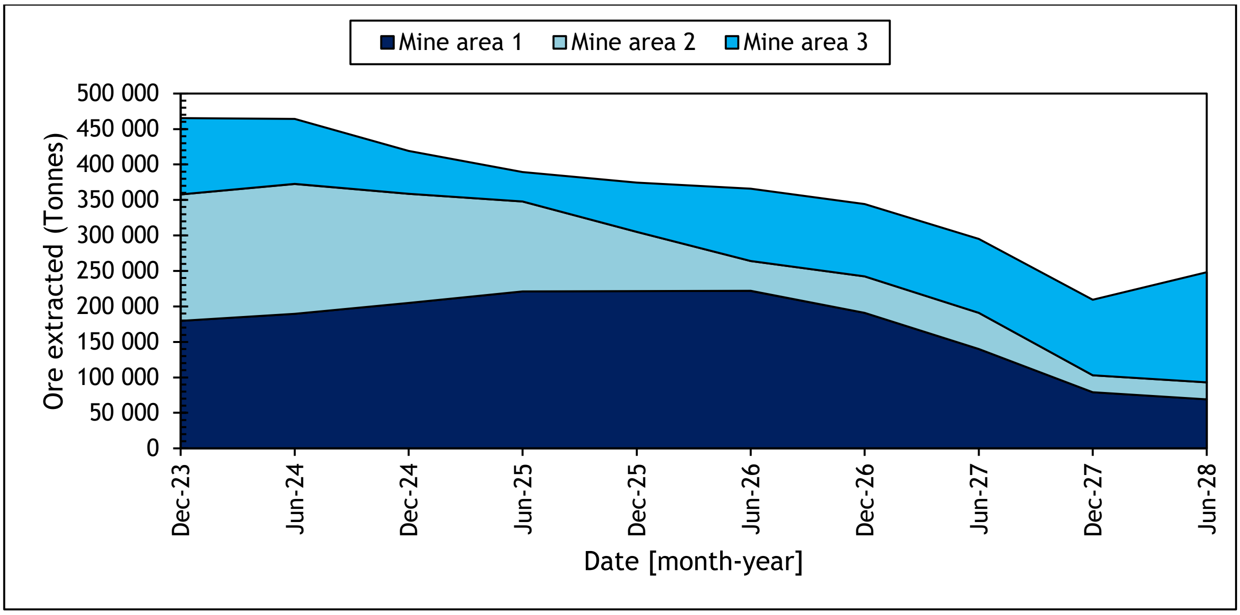

Figure 6: Planned ore extracted divided in 6-month increments

Figure 6 shows an overall decrease in production in especially in mine areas 1 and 2, but is also shows the increase in production in mine area 3 in more detail. This information will be utilised in the incremental planning method.

End-state planning method:

End-state ventilation planning involves the development of a ventilation system that can accommodate the end-of-mine-life (EOML) [29]. This involves factors such as mine closure, ore depletion, and changes in mining methods [29]. This is ideally done through simulation or other prediction models which predict the future state of the mine [29]. There has also been studies which have optimised ventilation systems for the EOML scenario in terms of airflow requirements, energy consumption, and capital cost [28]. This study will consider the EOML scenario as the end of phase 1 of the mine. This means that this study will consider June 2028 as the EOML, as indicated in Figure 6.

Step 2.2: The future mining area layouts

Mine areas 1 and 2 are not expanded during phase 1 since these are existing areas that are being mined out until the end of their LOM. Therefore, the only expansion of the digital twin that is required is at mine area 3. Figure 7 illustrates the future layout of mine area 3.

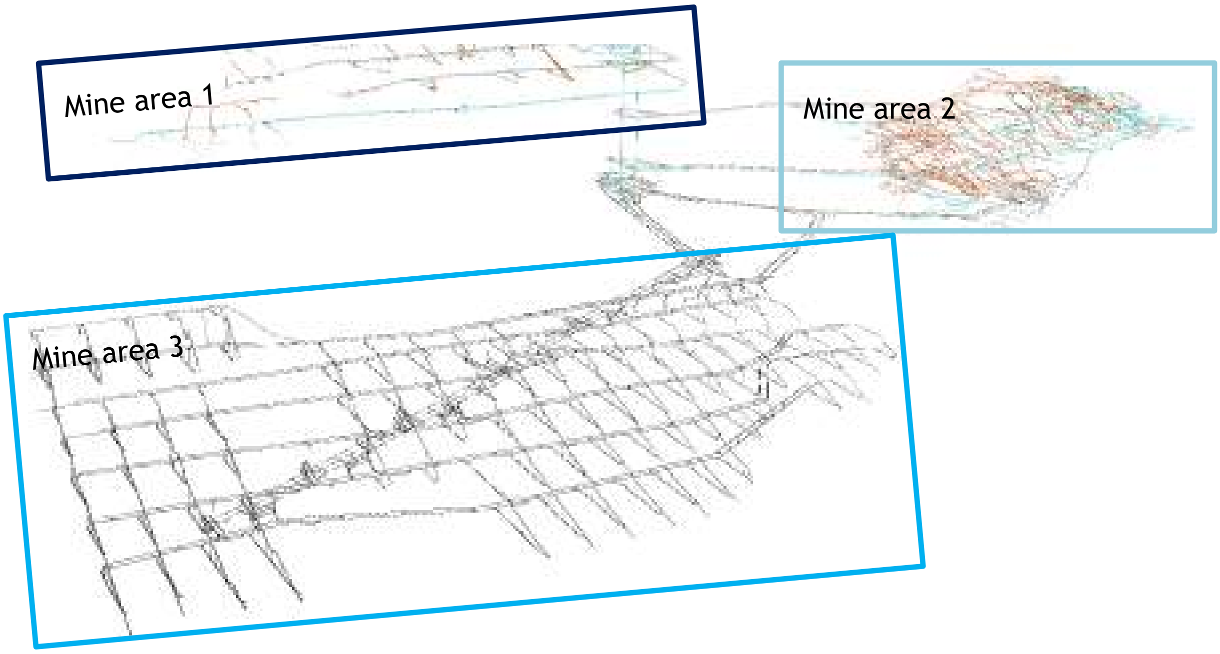

Figure 7: Mine area 3 EOML layout

Figure 7 shows the planned layout of the mine by 2046. This is a concept layout and is not necessarily what the mine area would look like at the end of the LOM. This is because the ventilation system has not been designed in detail to meet all the ventilation requirements. This layout is therefore only used as a base layout on which the ventilation system is planned.

Step 2.3: System requirements

The refrigeration and air flow quantity requirements for phase 1 should be determined to ensure that the existing infrastructure can accommodate the LOM plan. Figure 8 and Figure 9 illustrate the refrigeration- and air flow quantity requirements, respectively, for each mine area.

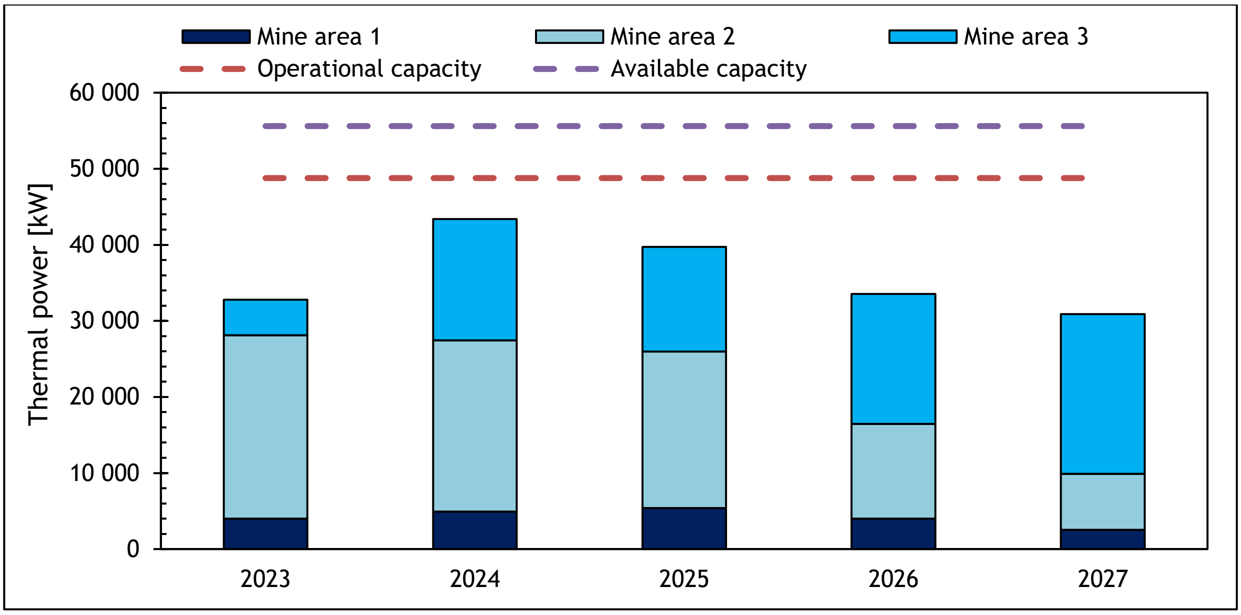

Figure 8: Refrigeration requirements for phase 1

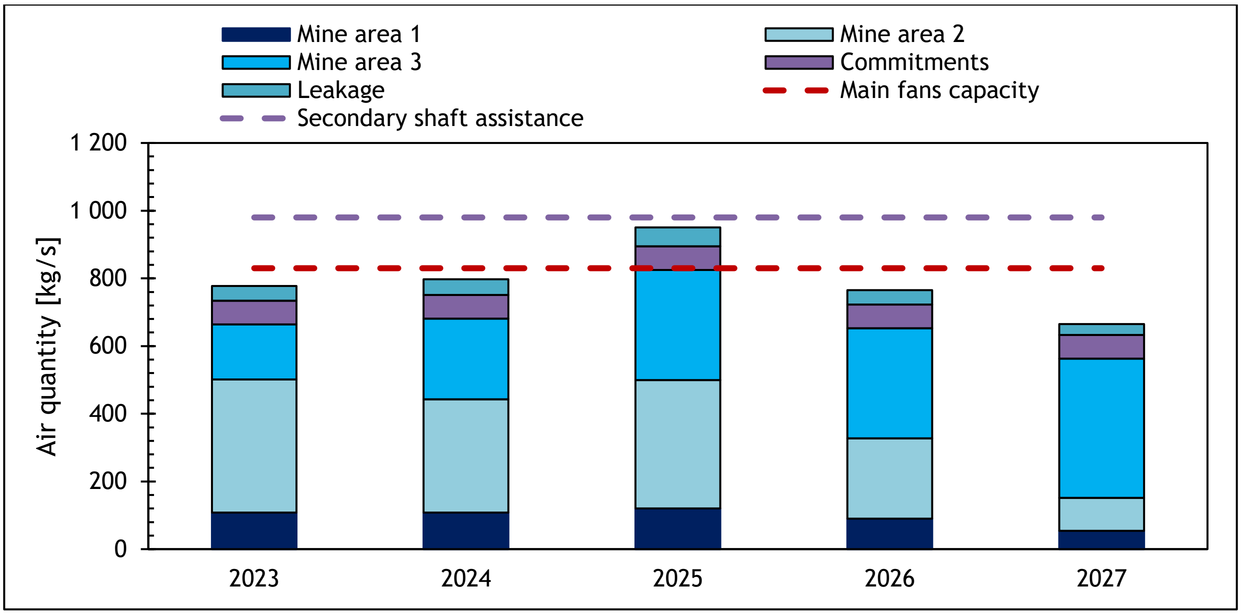

Figure 9: Air flow quantity requirements for phase 1

Figure 8 and Figure 9 show that the existing infrastructure will be able to accommodate the LOM plan during phase 1. It is also important to note that there are key performance indicators (KPIs) that should be evaluated during the planning process. The KPIs in this study are air temperature, air flow quantity, and air velocities. Table 1 indicates the requirements for the main KPIs.

Table 1: KPI requirements mine ventilation planning

KPI	Requirement
Air temperature	Stoping areas intake: • Wet-bulb < 26 °C • Dry-bulb < 35 °C Development end intake: • Wet-bulb < 28 °C • Dry-bulb < 37 °C Other accessible areas: • Wet-bulb < 32.5 °C • Dry-bulb < 37 °C
Air flow quantity	Stoping areas intake: • 15 m^3/s Conventional development ends: • 0.4 $m^3/s/m^2$ Trackless development ends: • 0.08 $m^3/s/kW$
Air velocities	Intake airways: • Conveyor belt airways – 4 m/s • Horizontal airways – 7 m/s • Shafts – 18 m/s Return airways: • Horizontal airways – 12 m/s • Shafts – 30 m/s • Ventilation holes – 30 m/s

Meeting these KPIs ensures proper ventilation and mitigates hazards like high temperatures, gas accumulation, and dust build-up.

Step 3: Expand digital twin

The model is expanded in different ways when implementing incremental or end-state planning. The difference in the planning methods is as follow:

End-state planning:

The end-state planning method requires the digital twin to be expanded to the end of phase 1. Figure 10 illustrates the expansion of the digital twin to the end of phase 1.

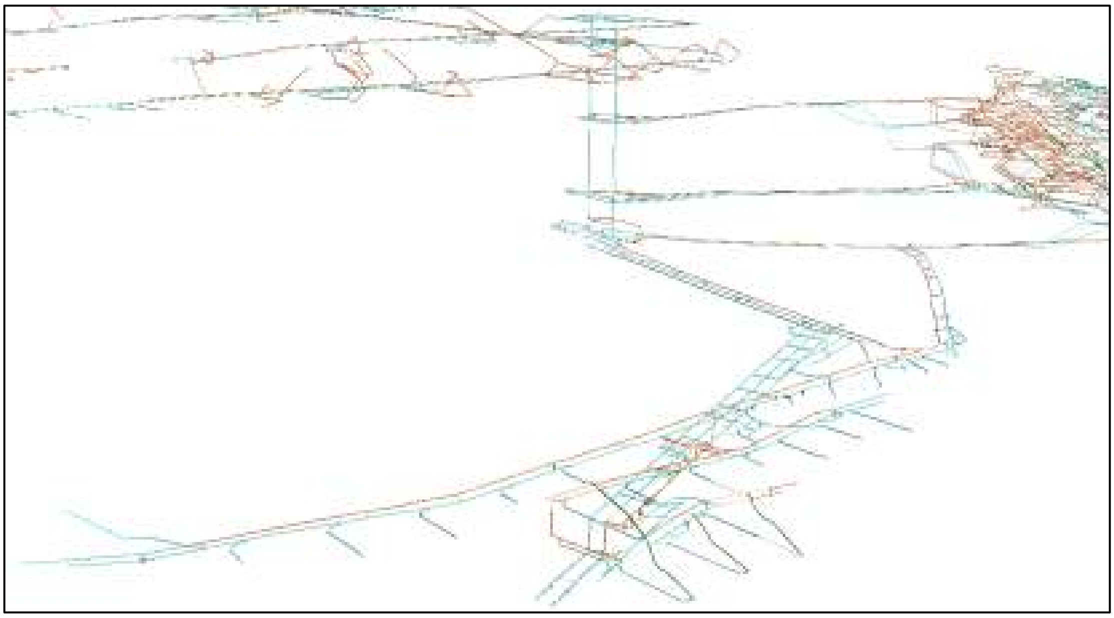

Figure 10: Digital twin expansion to end-state of phase 1

Figure 10 shows the digital twin model that will be used in the end-state planning method. The benefit of the end-state method in this step of the implemented strategy is that there is only one simulation model with its set of outputs to optimise.

Incremental planning method:

The expansion of the digital twin in the incremental planning method required the expansion to be divided into 6-month increments. Figure 11 illustrates the expansion and is colour coded to distinguish the increments.

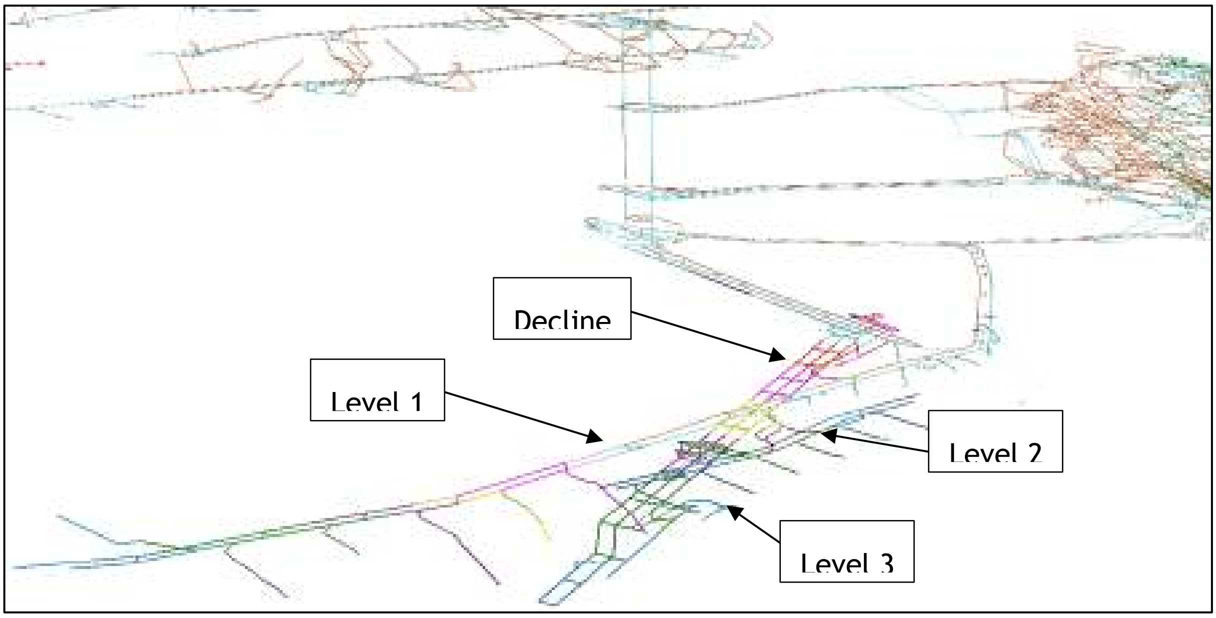

Figure 11: Digital twin expansion of phase 1 divided into 6-month increments

Figure 11 shows the 6-month increments in the mine's development during phase 1. This means that there will be 10 different simulations, each with their own set of outputs to optimise. This increases the detail to which the ventilation system is planned and designed.

Step 4: Detailed planning of LOM

The detailed planning of the LOM plan will now be completed by implementing both planning methods. It should be noted that the end-state model was designed according to standard ventilation practices. This includes:

- Force ventilation with auxiliary fans and steel ducting at all development ends.
- Force-exhaust ventilation at the decline where trackless diesel machinery is used.

There are also locations planned where bulk air coolers (BACs) and secondary booster fans are installed. The size and performance specifications were also determined from the heat load and airflow requirements, illustrated in Figure 8 and Figure 9. This information is used when optimising the ventilation plan.

The planning methods are implemented as follows:

End-state planning method:

As mentioned previously, the end-state planning method only requires one digital twin model with one set of outputs to optimise. The main areas that are being focused on are the decline airways, the horizontal development ends, and the stoping areas. Firstly, it can be seen in Figure 11 that there are three declines, namely the conveyor, service, and material declines. These declines provide fresh intake air to two active levels. There are also three development ends located on a level above these two levels which receives fresh air from the horizontal airways connected to the main intake shaft.

The focus is first placed on the airflow quantity supplied to each of these areas. Figure 12 illustrates the results from the end-state simulation model.

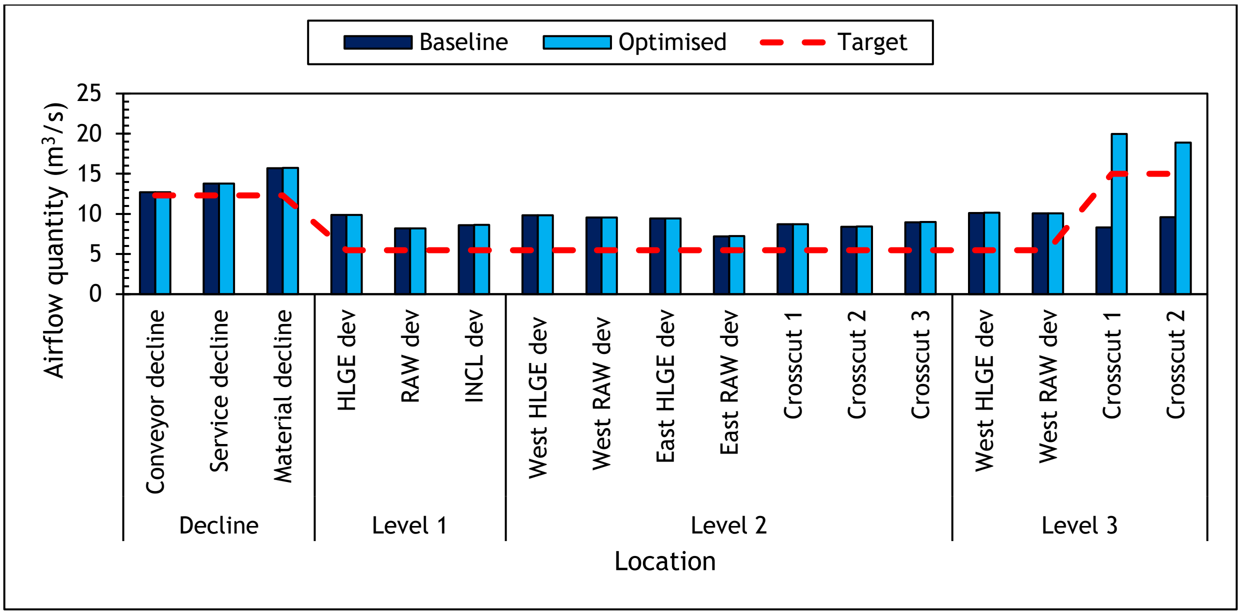

Figure 12: Airflow quantity at key locations (End-state planning method).

Figure 12 shows that the decline areas receive enough air to remove all the diesel particles. There are also sufficient air volumes being supplied to all development ends. The only areas which did not receive enough air were the two crosscuts on level 3. This was rectified by placing two 45 kW fans in tight circuit with a low-pressure door at each of these crosscuts. It should be noted that all areas in the model were evaluated to identify areas with stagnant airflow. There were no areas identified and therefor no areas are at risk of gas build-up. Figure 13 illustrates the air wet-bulb temperature results from the end-state model.

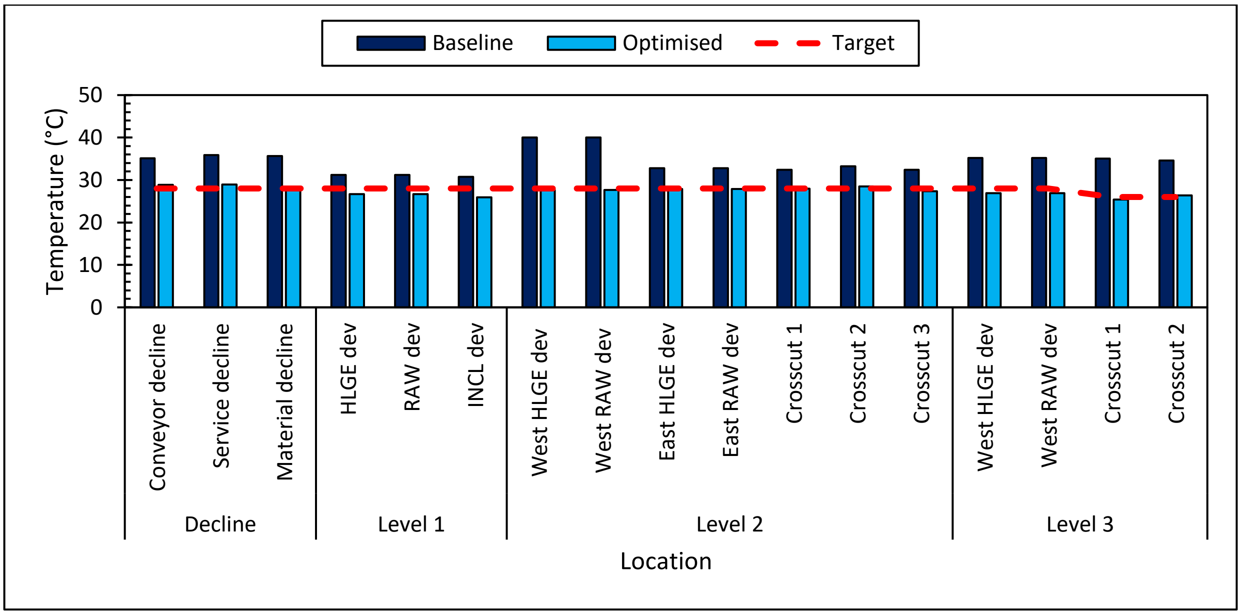

Figure 13: Air wet-bulb temperature at key locations (End-state planning method).

Figure 13 shows that all areas are above their target temperatures. The decision was then taken to start up all the planned BACs. It was also necessary to place a spot cooler in crosscut 2 of level 3. This resulted in all areas achieving their target temperatures.

This concluded the end-state planning method, and all hazards were mitigated. The incremental planning method will now be implemented, and focus will be placed on the same areas.

Incremental planning method:

The incremental planning method requires a different simulation model for every 6 months during phase 1 of the project. Each of these models yielded results that should be optimised. The focus is again firstly placed on the airflow supply to each of the key areas. Figure 14 illustrates the airflow quantity results of each of the simulated increments.

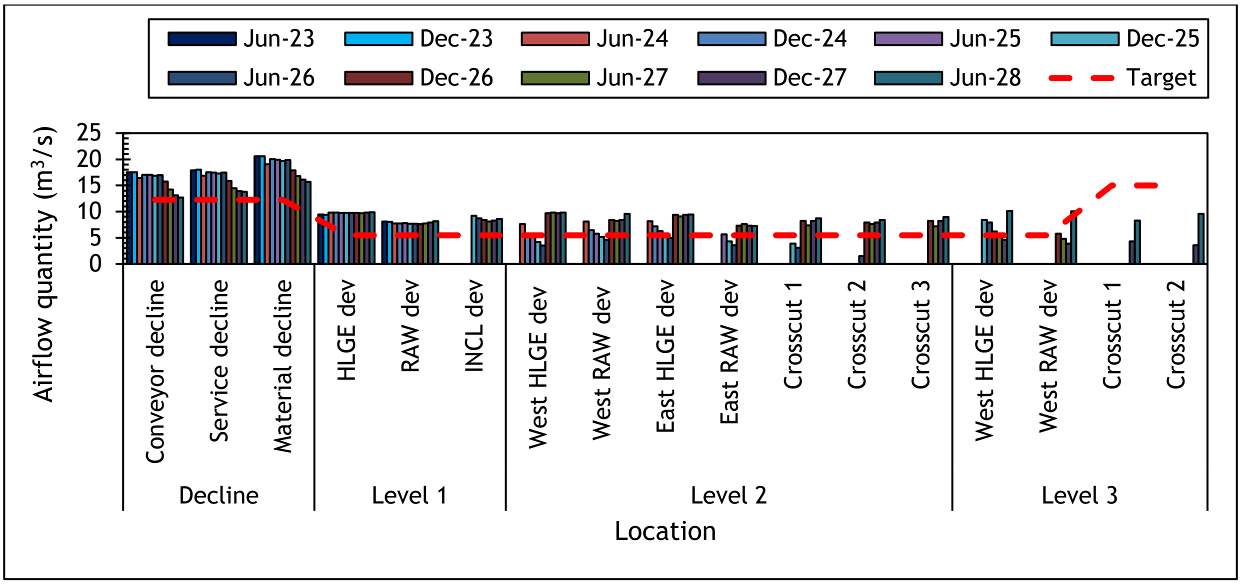

Figure 14: Airflow quantity at key locations (Incremental planning method).

Figure 14 shows that enough air will be supplied to the decline area development ends. There are also no shortfalls with air supply to the developments on level 1. Level 2 and level 3 do, however, have problems from December 2025. The next step will be to evaluate the air temperature results. Figure 15 illustrates the air wet-bulb temperature results.

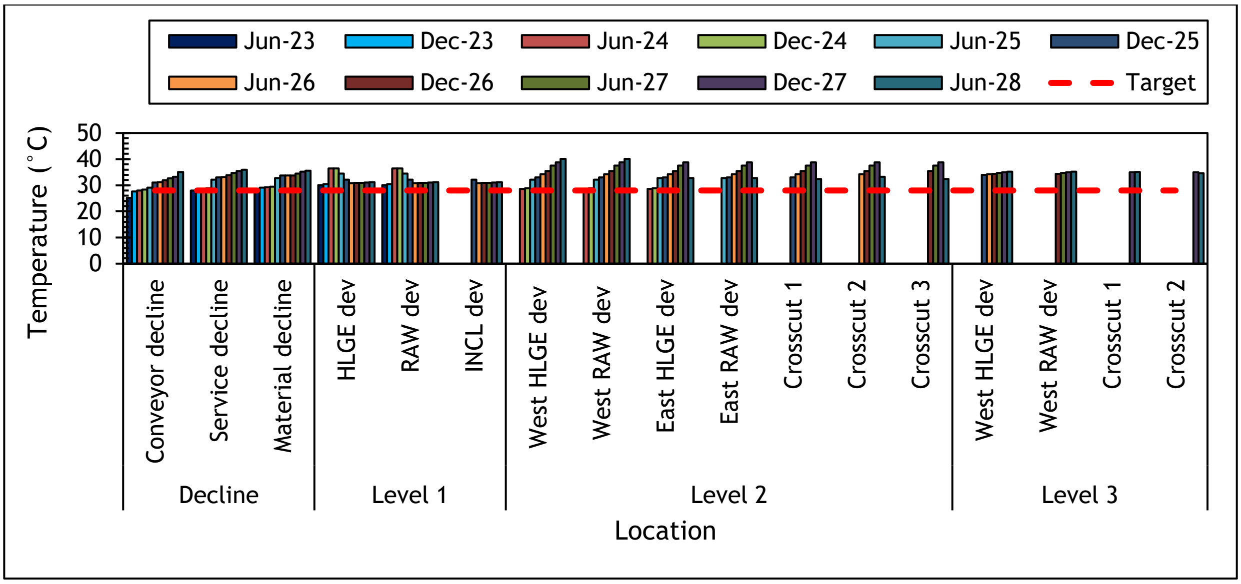

Figure 15: Air wet-bulb temperature results (Incremental planning method).

Figure 15 shows almost all areas will exceed the target temperatures. There are also excessive temperatures well above the legal limit [14] identified at level 2 and level 3. There also seems to be a decrease in temperature at level 1. This is mainly due to the closing of production areas which discharged hot air into the intake airway. The largest issue identified was the long distances that air had to be supplied by means of a force ventilation system. Figure 16 illustrates the excessive distances before the first planned ventilation hole.

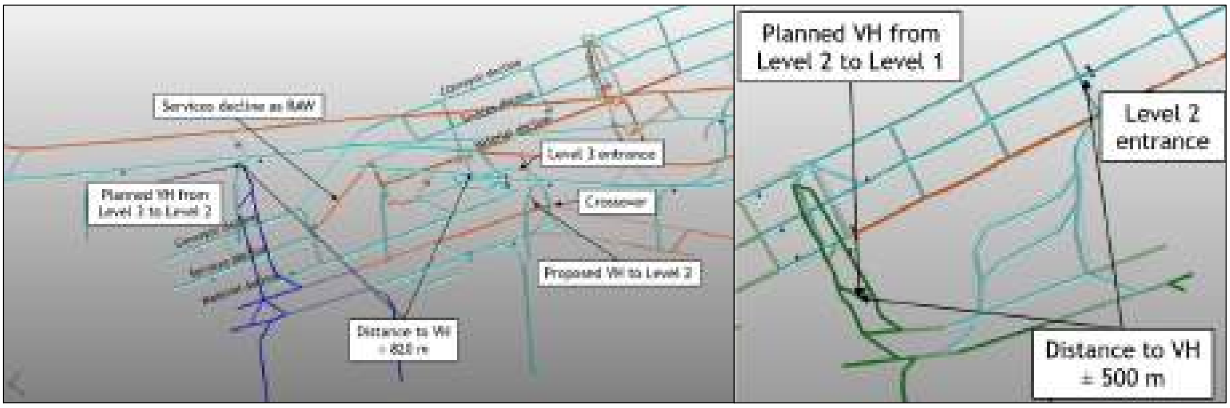

Figure 16: Identified issue on levels 2 and 3.

Figure 16 shows that the distances are more than 500 meters. The force ventilation system, which uses 45 kW fans, can only supply fresh air a distance of 250 meters. This is evident in Figure 14 where the target airflow quantity is not achieved after exceeding this distance. These issues can only be rectified by moving the planned ventilation hole (VH) closer to the entrance of the level. This, along with switching the planned BACs and booster fans on, will help achieve the desired airflows and air temperatures.

The benefit of incremental planning is not only establishing how to mitigate hazards but also establishing a deadline. This helps with planning the logistics surrounding the installation and commissioning of all ventilation and cooling infrastructure. Table 2 describes the timeline to commission the planned infrastructure.

Table 2: Timeline of commissioning of planned ventilation infrastructure

June 2023	• No actions required.
December 2023	• Start the first 2 MW BAC at the decline.
June 2024	• Start the second BAC at the decline. • Start the 2 MW BAC on level 1.
December 2024	• Start the first planned secondary booster fan.
June 2025	• Establish the newly planned VH from level 2 to level 1. • Start the third 2 MW BAC at the decline.
December 2025	• Establish the newly planned VH from level 3 to level 2.
June 2026	• No actions required.
December 2026	• Start planned 1 MW BAC on level 2.
June 2027	• Start planned 1 MW BAC on level 3.
December 2027	• Install 2 x 45 kW fans at crosscut 1 on level 3 in tight circuit.
June 2028	• Install 2 x 45 kW fans at crosscut 2 on level 3 in tight circuit.

Table 2 is the timeline that must be followed to ensure that all targets are met on-time. This will ensure that all hazards are avoided and mitigated before they occur, thereby ensuring a safe working environment as the mine is developed.

5 DISCUSSION

The two planning methods both yielded positive results in achieving the desired airflow supply and air temperatures. The main results can be summarised as:

- Insufficient ventilation during development phase if end-state planning method is followed.
- Planning and management of infrastructure is improved with the use of the incremental planning method.
- Both methods illustrated the same amount of cooling and airflow required with the only difference being when it is required and distributed.

There are benefits and shortfalls to both planning methods. Table 3 indicates the comparison between the two planning methods.

Table 3: Comparison between the end-state and incremental planning methods

End-state planning method		Incremental planning method	
Benefits	**Shortfalls**	**Benefits**	**Shortfalls**
Only one simulation model required.	Limited detail in development plan.	Increased detail in development plan.	Multiple simulation models.
Planning time is reduced.	Only information is what infrastructure is required by the EOML.	Timeline developed to commission critical infrastructure.	Increased planning time.
	Risk of delays in development due to hazards.	Reduced risk to delays in production due to a set hazard mitigation plan.	
	Airflow and temperature requirements only quantified for EOML.	Temperature and airflow requirements quantified at each increment.	

Table 3 shows the main comparison point between the two planning methods. The most important being the fact that there is a reduced risk in delays in production due to the detailed hazard mitigation plan. The incremental planning method is therefore best suited for the planning of the ventilation system of a large development such as the one discussed in this paper. The end-state planning method remains valid and is ideal for time-constrained situations when assessing the feasibility of planned infrastructure to support suitable working conditions. The main objective of this study was to compare the two planning methods. Table 3 summarised the main benefits and shortfalls and thus the objective is achieved.

6 CONCLUSION

The comparison between two ventilation planning methods discussed in this study yielded interesting results. The methods were both able to mitigate all identified hazards. There were, however, major problems identified through the incremental method, which were not identified by the end-state method, illustrated in Figure 16.

The risk of a delay in the development of the mine is reduced and safe working conditions throughout development is assured. The end-state planning method does have benefits such as the ability to evaluate the planned infrastructure. The incremental planning method does, however, have the added benefit of creating a timeline of when the planned infrastructure is to be installed.

In conclusion, when planning deep-level mines with a long LOM, the incremental planning method proves to be the most suitable approach for ventilation systems. Its adaptability and flexibility makes it well-suited for accommodating the evolving needs of such complex mining operations over extended periods of time.

Additionally, it is worth noting that the incremental planning method can be successfully applied to any deep-level mine ventilation system. By utilizing this method, mine planners can ensure the efficient and sustainable functioning of ventilation systems throughout the entire lifespan of the mine, ultimately contributing to the safety and productivity of the workforce in deep-level mining environments.

ABSTRACT

South African deep-level gold mining operations are extremely stressed due to the ever-increasing energy tariffs. These operations are complex systems with services' (compressed air and water) pipelines reaching lengths of over 100 km to supply end-users. Harsh underground conditions tend to cause inefficiencies due to leakages and misuse. Due to the complex nature of the system, identifying inefficiencies can be difficult and time-consuming. Furthermore, services' monitoring is only done up until the half level splits. However, inefficiencies tend to occur closer to the working areas. Therefore, it is proposed to install flow/pressure meters in each working area and isolate it as a business unit. Dynamic zero-waste baselines were developed for each business unit to monitor service water consumption. Through this, an annual energy cost benefit of approximately R19 million was achieved. Comparing actual consumption against dynamic zero-waste baselines will help to keep personnel accountable for inefficiencies in their area.

Keywords: Zero-waste baseline, responsibility allocation, dynamic approach, deep-level mine, water reticulation system, inefficiency detection, energy savings

1 INTRODUCTION

1.1 Background

The sustainability and profitability of the gold mining industry in South Africa are in question due to the ever-increasing operating costs [1]. Between 2013 and 2022, the average operating cost of South African gold mines have increased by approximately 54% [2], [3]. This can mainly be attributed to South Africa's electricity cost tariff that has increased by approximately 653% from 2007 to 2022, compared to inflation's increase of 129% over the same period [4]. Therefore, if South African gold mining operations are to extend their life-of-mine (LOM), there is a need to investigate and exploit alternative opportunities to decrease operational costs [5].

1.2 Service water in South African deep-level mining

The South African gold mining industry is extremely energy-intensive, consuming approximately 30% of the total power supplied by South Africa's power utility, Eskom [6]. The water reticulation system on deep-level gold mines consumes as much as 39% of the total energy consumption allocated per operation. Figure 1 depicts the electricity distribution on a typical South African deep-level gold mine, with the "pumping" (25%) and "refrigeration" (14%) utilities representing the total energy consumed by the water reticulation system [7].

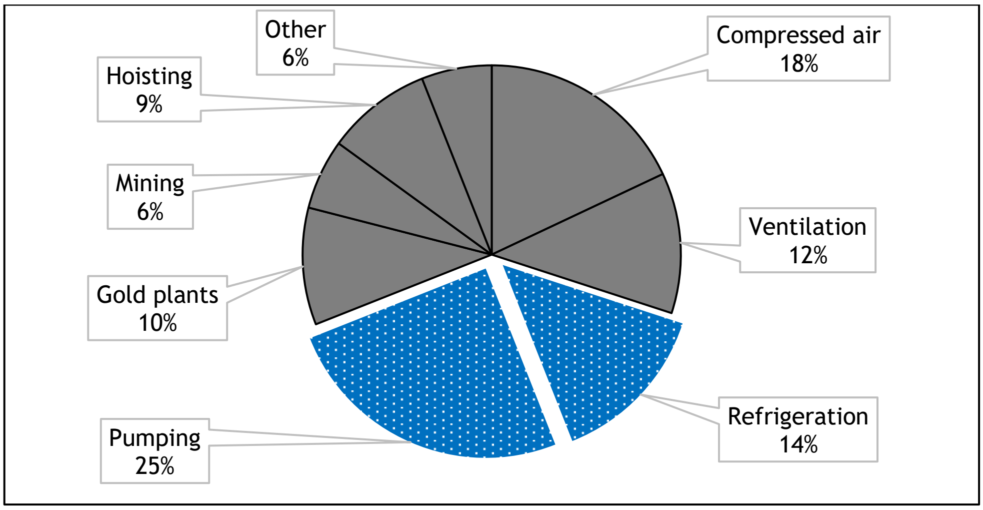

Figure 1: Electricity distribution on a typical deep-level gold mine [7]

South African gold mining operations are complex systems, reaching operational depths of up to 4 000 m [7]. This results in service pipelines reaching lengths of up to 100 km to supply end-users with service water [8], [9]. Figure 2 illustrates the complexity of deep-level mines using a typical gold mining layout.

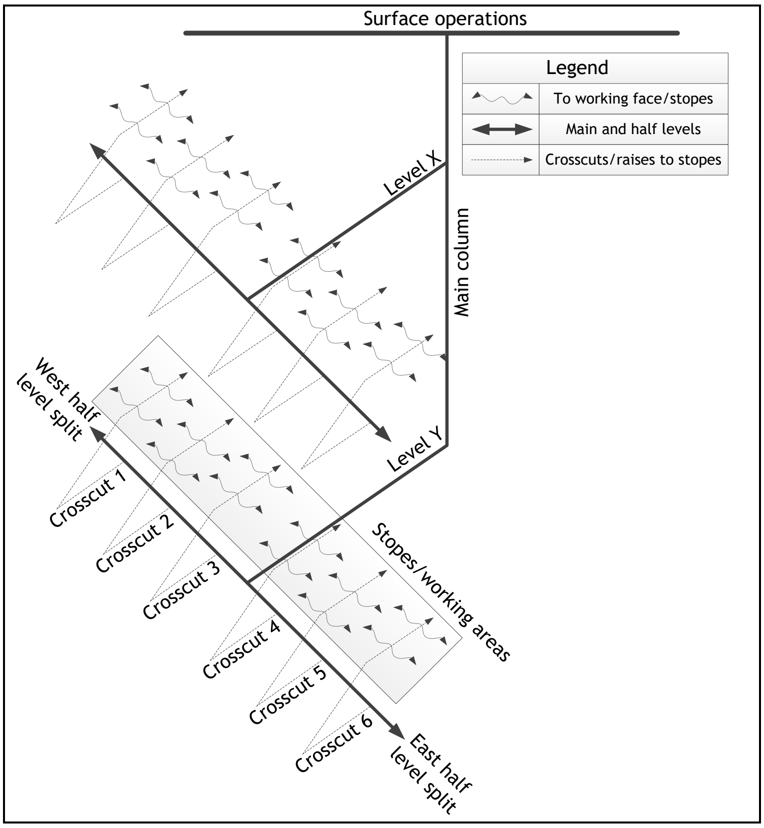

Figure 2: Typical deep-level gold mine layout

The service water is used for underground air cooling and mining activities which include the cooling of rock drills, cleaning/sweeping, and dust suppression [10]. These activities occur in the stopes/working areas depicted in Figure 2.

The water demand relies on the designated mining shifts and the equipment allocated for various activities occurring during each duty cycle. [11]–[13]. The process of underground mining is divided into a number of steps that occur in shifts throughout the day and night, forming a 24-hour cycle. The typical mining shifts (along with their duration) of a South African gold mine are as follow (with the main water-consuming equipment noted for each shift) [11]–[14]:

- Drilling (from 06:00 to 14:00):
  - Rock drills are used to drill holes in the rockface for inserting explosives. Service water is used to cool down the drill bits of the rockdrills.
- Explosive charge-up and blasting (from 14:00 to 16:00):
  - Explosives are inserted into the drilled holes, whereafter the rockface is blasted. No personnel are allowed near the blasting site during this time which means that theoretically, no water should be consumed.
- Non-entry period (from 16:00 to 21:00):
  - Following the blasts, a waiting period has been allocated to allow for dust and harmful gasses to be ventilated out of the mine. Again, no personnel are permitted underground during this period which means that no water should be consumed in the working areas.
- Cleaning and sweeping (from 21:00 to 04:00):
  - Waterjets are used to move broken rock to the collection point. The gold-bearing rock will be transported out from underground to be treated at the gold plants.

- Shift change (from 04:00 to 06:00):
    - This entails the change between the drilling and cleaning/sweeping shift. Personnel that worked during the cleaning/sweeping shift will make their way out of the stopes to the main shaft to be hoisted from the mine. The drilling shift personnel will start to make their way to the stopes. Theoretically, no water should be consumed during this period as personnel are on-route to and from the stopes.

Each mining operation may have different timetables for the listed duty cycles but consist of the same method of operation. Therefore, these schedules are merely an example of a typical mining schedule, and deviations are expected for each mining operation. It should be noted that the only water users that consume water continuously throughout the day, regardless of the mining shift, are underground cooling units such as bulk air coolers and mobile cooling units.

1.3 Service water inefficiencies

In an ideal world, the water supply should match the demand when referring to the law of mass conservation [15]. However, studies have found that approximately 50% of the total consumed water demand can be attributed to system inefficiencies [16], [17]. Inefficiencies can mainly be attributed to:

- Leaks [18]–[21], and
- Misuse and malpractice [18], [19], [22]–[26].

In addition to the cost implications, inefficiencies negatively affect system performance. These can include operating pressures, water availability and storage [20], [25], [27]. Seeing that the system performance is negatively affected, control room operators start up additional equipment on surface to account for the inefficiency losses. This results in additional energy usage where the cost implications thereof requires justification by the appointed upper-level management [20], [27].

Therefore, it is of critical importance that these inefficiencies are mitigated. However, before inefficiencies can be mitigated, they must be identified. This is a very difficult and time-consuming process due to the complex nature, harsh environment, and magnitude of South African gold mining operations [17], [19].

1.4 Current inefficiency identification and monitoring

Most inefficiencies tend to occur closer to the stopes/working areas where the gold-bearing ore is mined [20], [28], [29]. However, services monitoring is typically limited to the half-level split, making it impractical to identify exactly where the inefficiencies are located by merely using metered data. In addition, further processing of the data is required to be able to quantify inefficiencies [19].

Existing inefficiencies detection- and quantification methods are summarised below:

1. **Intensive underground audits**
   Underground audits involves the process where personnel must go underground and visually detect inefficiencies [22], [24], [30]–[33]. This method is very resource-intensive, impractical, and dangerous as auditors may need to enter abandoned and dangerous areas to locate these inefficiencies [20], [22], [34]. Auditing one level can typically take a team an entire day, which means that only the data of the specific day will be available [19]. This prevents effective and continuous monitoring.
2. **Step testing**
   Step testing is classified as a manual method where flowmeters are installed upstream of the tested area [19], [35], [36]. Certain areas will be isolated individually to

determine which areas have the largest leakage rate. Recent case studies used step testing to identify inefficiencies [37]–[39]. The pitfall is that inefficiency detection can only be done when no mining activities are present, and therefore this method does not identify inefficiencies while mining activities are underway.

3. **Zero-waste baselines**
   A zero-waste baseline is defined as a theoretical minimum consumption that is used to measure the amount of wastage of a particular system [15], [34].
   A recent study conducted by Van der Merwe [40] made use of zero-waste baselines to identify inefficiencies. Van der Merwe used the best operating point of the mining equipment to develop a zero-waste baseline. This baseline was simulated to develop a theoretical baseline. Actual data was compared to the baseline to identify wastages.
   Even though Van der Merwe's study delivered promising results, the baselines were only constructed per level. This means that inefficiencies are indicted too broadly and is still too far from the working areas. Equipment performance varies under various conditions. Using the best operating point will thus not suffice. In addition, certain factors affect the water usage throughout the day and may differ daily [40],[41]. These factors should also be accounted for as inaccurate baselines will become obsolete [42].
4. **Hardware- and software methods**
   Hardware-based methods require equipment such as sensors, optical fibres, hydrophones, or radar systems to identify inefficiencies [32], [43]. Software-based methods use extensive datasets for processing [32], [44]–[48]. These methods have proven to be time-consuming, resource intensive, and expensive [49].
5. **Benchmarking**
   Benchmarking has been proven to be a powerful tool which involves comparing the actual performance of an entity to that of a reference performance [45], [50]–[53]. A recent study conducted by Du Plooy [32], [34] developed a benchmarking model that used a mining level's compressed air consumption and production. However, this method prioritised levels based on their production. Auditors were still required to locate leaks in pipe columns of up to 10 km long.

Previous research has proven helpful in the process to identify inefficiencies on mine services, but localised leak detection remains largely unexplored.

It is worth noting that Zietsman [19] highlighted concerns about installing additional instrumentation near working areas in South African mines due to associated capital implications. However, the continuous increase in electricity tariffs and significant wastage factors have compelled South African mining operations to undertake drastic measures to reduce operating costs and ensure the longevity of their operations. The potential savings benefits outweigh the initial capital expenditure.

A recent survey conducted by Axora [54] revealed that only 60% of mining budgets allocated to digital transformation are utilised, with the remaining 40% left unused due to a lack of understanding regarding potential benefits of digital solutions. This indicates that mining operations are not fully aware of the potential benefits that can be achieved by installing flowmeters in close proximity to the working areas. By closely monitoring these areas, inefficiencies can be detected much faster than previous methods, allowing for precise identification at the stope/working area level.

1.5 Problem statement and objectives

The absence of accurate inefficiency detection methods in South African gold mining operations hampers the ability to identify and address inefficiencies effectively, resulting in increased operational costs and reduced sustainability.

The literature revealed the necessity for enhanced localised inefficiency detection near working areas in underground mines. Zero-waste baselines has proved to successfully identify wastages. However, seeing that conditions underground differ daily, the static approach followed by previous researchers will not suffice.

An effective solution is needed to dynamically identify, mitigate, and monitor system inefficiencies in deep-level gold mine service water networks.

To achieve this, each working area must be treated as a separate business unit. Flow- and pressure sensors need to be installed in close proximity to the working areas to monitor the service water consumption of each entity. This approach will facilitate the development of a dynamic zero-waste baseline, incorporating equipment performance under specific conditions, equipment time-of-use, and personnel activity. The implementation of this innovative inefficiency detection method will lead to quicker and more effective identification of inefficiencies, ultimately promoting service sustainability.

The objectives of the method can be summarised as:

- Development and implementation of dynamic zero-waste baselines
- Inefficiency detection and continuous monitoring for sustainability
- Energy- and water savings through inefficiency identification and rectification

This paper will develop a novel and more effective inefficiency management method, focussing on the detection of inefficiencies.

2 NOVEL INEFFICIENCY DETECTION METHOD DEVELOPEMENT

The proposed method to solve the objectives of this paper will be developed in this section. The steps are displayed in Figure 3 and will be briefly discussed.

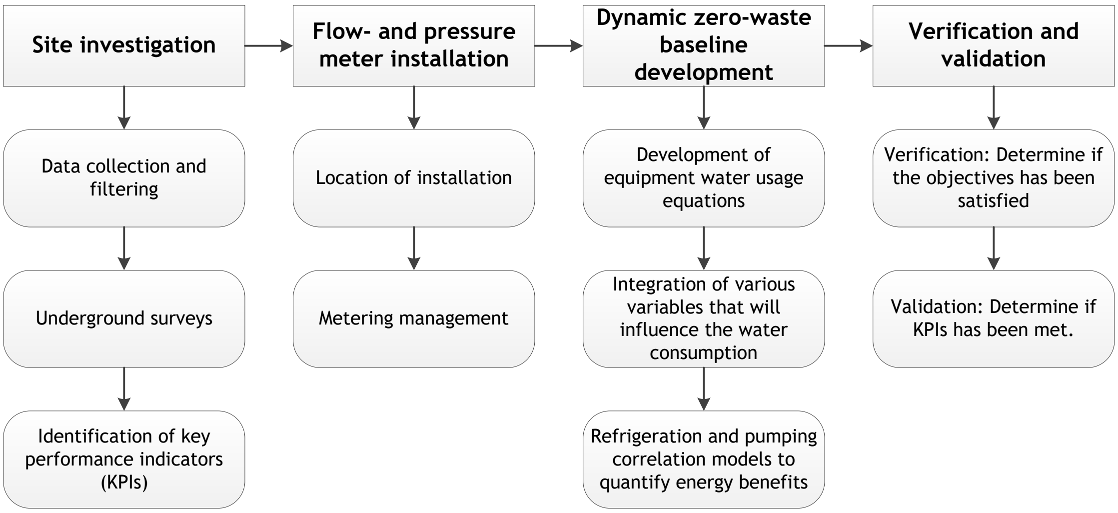

Figure 3: Proposed method development for inefficiency detection

2.1 Site investigation

The initial phase involves an extensive examination of the system, encompassing the process of data gathering and filtering. The essential data to be collected includes equipment lists of water users, their respective locations, and specification sheets. Additionally, stoping and development plans, mining standards, missing persons locator (MPL) networks, mining schedules, and flow/pressure readings obtained from installed sensors are also deemed as critical data required. Underground surveys will be conducted to identify typical wastages in working areas.

Key performance indicators (KPIs) will be identified that should be met to validate the method.

2.2 Flow- and pressure meter installation

To strategically position the sensors, the stoping and development plan will be utilised to identify areas with the longest operational life and planned tonnes.

The flow- and pressure sensors will be installed after the continuous water users (bulk air coolers and mobile cooling units) to only monitor the water to the stopes/working areas as illustrated in Figure 4.

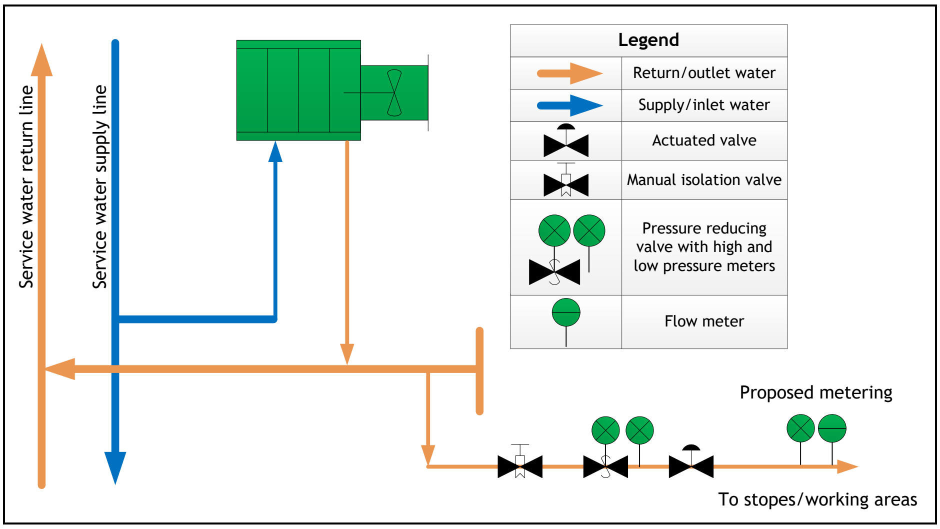

Figure 4: Typical water flow layout to working areas

When the working area closes, the metering will remain in place until the area has been entirely blanked off. This will prevent abandoned areas from wasting service water. It will be the responsibility of the person in charge of the abandoned area to move the metering to the next operational business unit.

2.3 Dynamic zero-waste baseline development

In this section, the dynamic zero-waste baseline will be developed. The developed baseline should be accurate to prevent the baseline from becoming obsolete (mentioned in section 1.4).

Firstly, correlation models will be employed to establish a formula that quantifies water usage for the equipment across varying water pressures, leveraging the information provided in the specification sheets of the equipment. Table 1 presents an example of the typical data extracted from the equipment specification sheets for rockdrills, showcasing the water usage corresponding to different water pressures.

Table 1: Equipment specification sheet example

Point	Pressure [bar]	Water usage [l/min]
A	0.50	3.50
B	1.00	3.80
C	1.50	3.90
D	2.00	4.30
E	2.50	4.80
F	3.00	5.20
G	3.50	5.60

The correlation between water usage and pressure is then examined, followed by the selection of the most suitable trendline that exhibits an r-square (R^2) value closest to one [55]. A typical example, using the data in Table 1, is shown in Figure 5.

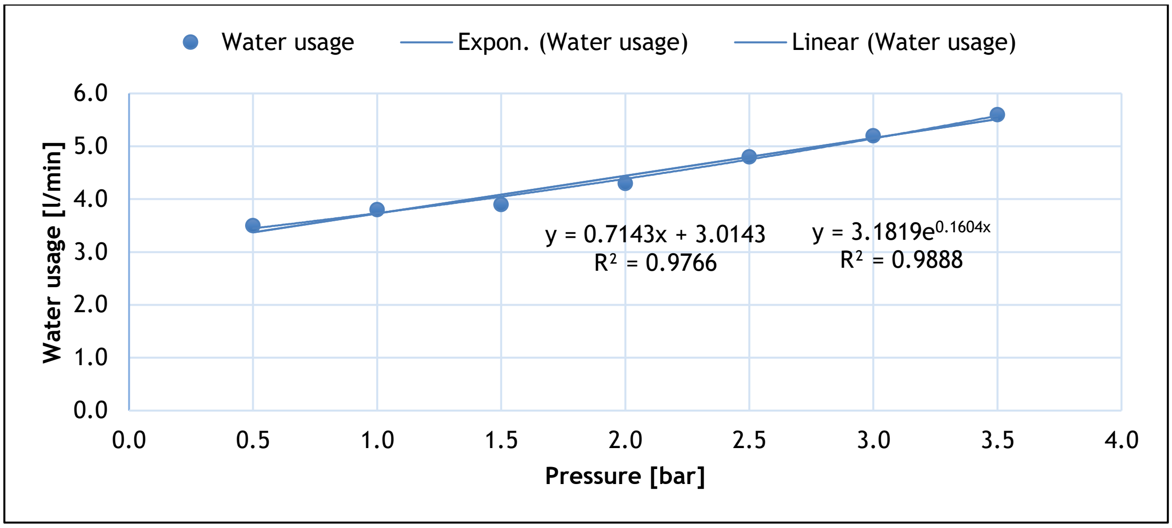

Figure 5: Example of the correlation between water usage and pressure for rockdrills

The known pressures from the specification sheet will be used in the developed formula to calculate the water usage. The calculated water usage should then be compared to the actual/specification sheet's water usage to determine the accuracy. A typical example is shown in Table 2. The model accuracy will be determined by using the Mean Absolute Percentage Error (MAPE) [56]. MAPE indicates the absolute error between the predicted and actual value by using Equation 1 [56]. A MAPE of smaller than 10% is considered a highly accurate model [57].

$$MAPE = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{A_t - F_t}{A_t}\right| \tag{1}$$

Here:

$MAPE$ - Mean absolute percentage error [%]

n - number of entries [-]

A_t - Actual value

F_t - Predicted value

Table 2: Example of MAPE between actual/specification sheet and calculation

Point	Pressure	Actual/specification sheet: Usage	Calculation: Usage	MAPE
A	0.50	3.50	3.45	1.50%
B	1.00	3.80	3.74	1.70%
C	1.50	3.90	4.05	3.78%
A	2.00	4.30	4.39	1.99%
B	2.50	4.80	4.75	1.01%
C	3.00	5.20	5.15	0.99%
A	3.50	5.60	5.58	0.39%

A simulation model is then developed to test and confirm the accuracy of the develop formula at different operating pressures.

The water pressure within the designated business unit will be utilised in conjunction with the derived equation to determine the water usage of the equipment, accounting for variations in water pressures throughout the day. It should be noted that certain water users, such as waterjets, employ power packs to elevate the water pressure to the designated operating pressure, resulting in consistent water usage during operation. Consequently, it becomes necessary to allocate the water user to the corresponding specified mining shift during which it is utilised. The underground surveys and case study investigation will assist with the equipment time-of-use which should correlate to the information provided in section 1.2.

The MPL data will be used to determine the personnel activity in the specific business unit. MPL networks is an occupancy detection method. The system is used to track employees' last location in case of an emergency [58]. Personnel is tracked by means of strategically placed antennae and receivers underground. Personnel that go underground will be equipped with a cap-lamp which is fitted with a short-range radio frequency identification tag. As the worker walks by the antennae underground, the receivers detect the cap-lamp and stores the data [58].

The system will determine the water allocation to the working areas throughout the day based on the personnel activity. Fixed schedules are not sufficient to determine the required water allocation, seeing as it only provides information relevant to the levels, and not sufficient detail on what is happening in the working areas. Personnel have planning meetings before entering their working area, which differs for each business unit. As indicated in section 1.2, it is theoretically expected that no water should be consumed during shift changes as personnel transition to- and from working areas. However, it should be noted that rockdrills will consume water during drilling shifts, while waterjets will utilise water during the cleaning/sweeping shift.

By incorporating these factors, the dynamic zero-waste baseline will be established, which will dynamically adjust according to the personnel activity and fluctuating water pressures. These factors will vary daily, resulting in a distinct baseline for each day. Consequently, a more precise and realistic baseline can be formulated. Furthermore, with the data available, the baseline will be able to update hourly, resulting in instantaneous inefficiency detection.

Next, the energy wastage will be determined by using the correlation models for the pumping- and refrigeration systems. The correlation is determined by Equation (**2**.

$$Correlation\ factor = \frac{E}{Q} \tag{2}$$

Here:

$Correlation\ factor$ – correlation between the energy consumed to pump/cool water [kWh/l/s]

E – energy consumed [kWh]

Q – water pumped/cooled [l/s]

The actual water consumption per business unit will be compared to the corresponding baseline water consumption to assess the amount of pumping- and refrigeration energy that is wasted, which correlates to the water volumes wasted. Utilising the pumping- and refrigeration correlation factors, immediate impacts can be identified and promptly communicated to the appropriate personnel for necessary action. This facilitates quicker and more efficient feedback loops.

2.4 Verification and validation

The method will undergo verification and validation to determine the efficacy thereof in addressing the problem at hand. The identified method objectives will serve as a criterion for the verification, whereas the identified KPIs will be compared to the outcomes of the implemented method for validation.

3 IMPLEMENTATION AND RESULTS

The developed method will be implemented on a case study (Mine X) to determine the effectiveness thereof.

3.1 Site investigation

As this paper focusses on the reduction of energy- and water consumption, the identified KPIs are:

- Pumping- and refrigeration energy consumption, and
- Water consumption.

3.2 Flow and pressure meter installation

The stoping and development plan was used to determine where flow- and pressure meters should be installed. The capital costs amount to approximately R60 000 per business unit. Initially, three specific areas have been identified for the installation of flow- and pressure sensors. The results will be showed for a working area (Business unit 1) with an operational life of 25 months. All other working areas/business units were calculated on the same principle.

3.3 Dynamic zero-waste baseline development

The waterjets have a constant water flow of 160 l/min when operated. The rockdrills' water usage will differ based on the supplied water pressure. From the rockdrills' specification sheet, the exponential correlation, with a R^2 value of 0.9975, between the rockdrills' water usage (y-axis) and pressure (x-axis) is displayed in Figure 6. This was calculated by using Microsoft Excel.

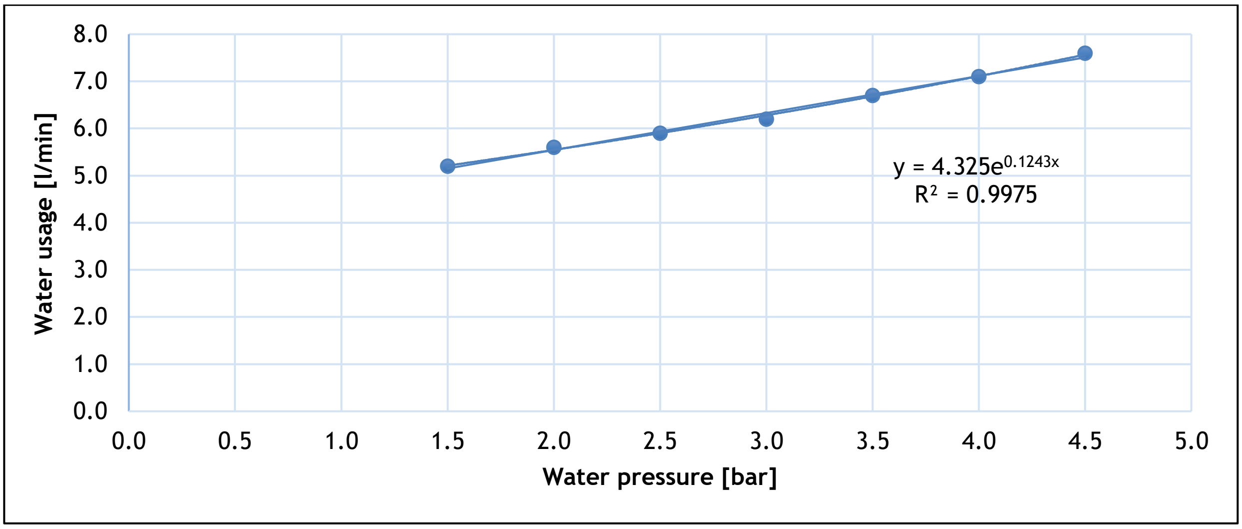

Figure 6: Correlation between water usage and pressure for rockdrills

Equation 3 has been derived from the equation seen in Figure 6 to represent the water usage of rockdrills at various pressures.

$$Q = 4.325xe^{0.1243xP} \quad (3)$$

Here:

Q – Water usage [l/min]

P – Water pressure [bar]

(**3**) was utilised to calculate the water usage at the specified pressures mentioned in the specification sheet and subsequently compared with the actual/specification sheet water usage to confirm the accuracy thereof as seen in Table 3. The model accuracy was calculated as 99.61% using MAPE, therefore, it can be concluded that the formulated equation is accurate and reliable.

Table 3: Developed formula compared to the actual/specification sheet for rockdrills

Pressure [bar]	Actual/specification sheet water usage [l/min]	Calculated water usage [l/min]	MAPE
1.50	5.20	5.21	0.22%
2.00	5.60	5.55	0.98%
2.50	5.90	5.90	0.02%
3.00	6.20	6.28	1.27%
3.50	6.70	6.68	0.26%
4.00	7.10	7.11	0.15%
4.50	7.60	7.57	0.44%

In addition, the rockdrills and waterjets were also incorporated into a simulation model to check and confirm the accuracy of the developed formula (equation (**3**). The Process Toolbox (PTB)[1] simulation software was used. The water pressure values as seen in Table 3 were integrated into the simulation model to determine the water usage and subsequently compare it with the water usage calculated using the developed formula. The MAPE between the simulation model and the developed formula has been calculated as 2.12%, confirming that the accuracy of the developed formula is acceptable.

Figure 7 illustrates the MPL data along with the mining shift schedule for Business unit 1.

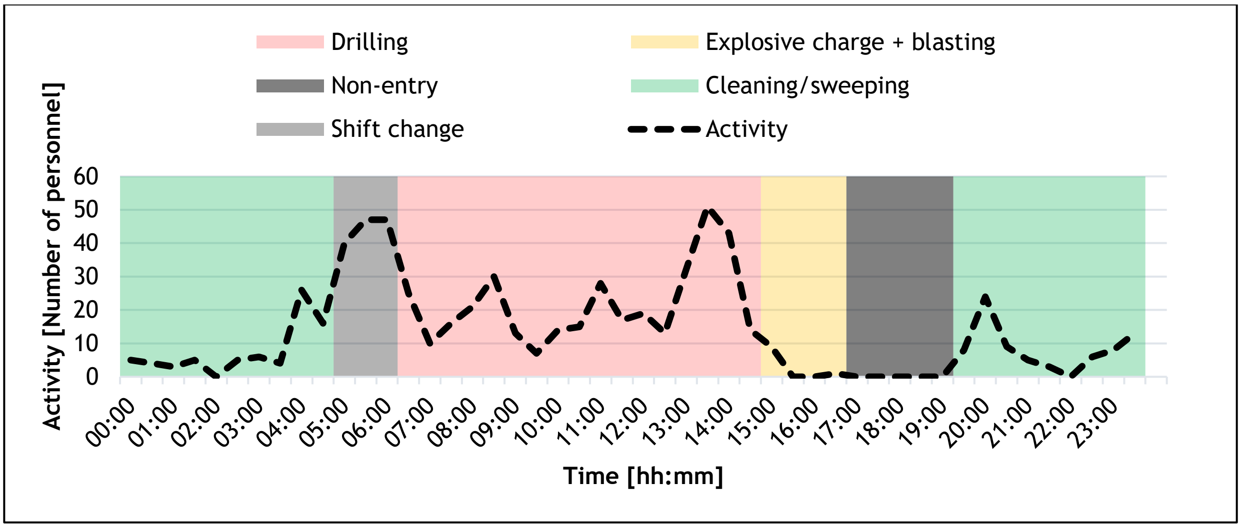

Figure 7: Personnel activity during different mining shifts

The dynamic zero-waste baselines were constructed for Mine X. Figure 8 showcases the dynamic zero-waste baselines for Business unit 1 over five distinct days. These baselines vary daily due to several factors mentioned previously.

[1] PTB is a user-friendly thermal hydraulic simulation software package that enables users to design, analyse and optimise a system's performance which is owned by MCI (Pty)©.

Each business unit possesses unique factors that impact the baseline differently, although the underlying principles on which they were developed remain consistent.

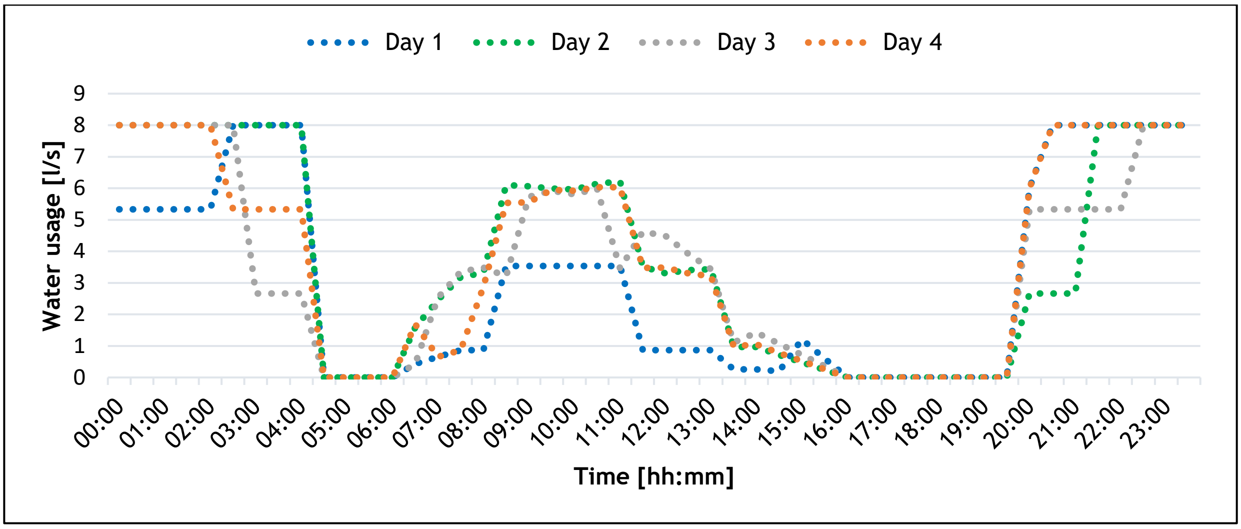

Figure 8: Dynamic zero-waste baselines for business unit 1

Figure 9 and Figure 10 depicts the pre- and post-implementation results for Business unit 1 (results before and after the rectification of identified inefficiencies). Here the measured actual water usage, as captured by the installed flow meter, is displayed alongside the corresponding dynamic zero-waste baseline. Additionally, the MPL data for the particular scenario is also depicted in the figures. This visual representation provides a comprehensive view of the real-time water flow, the baseline comparison, and the personnel activity recorded by the MPL system for the specified day.

When referring to the pre-implementation results depicted in Figure 9, we see that water was still consumed during periods where no personnel was working. This mean that the water consumed during these times are contributed to wastages. Furthermore, additional water was used during the drilling and cleaning/sweeping shifts.

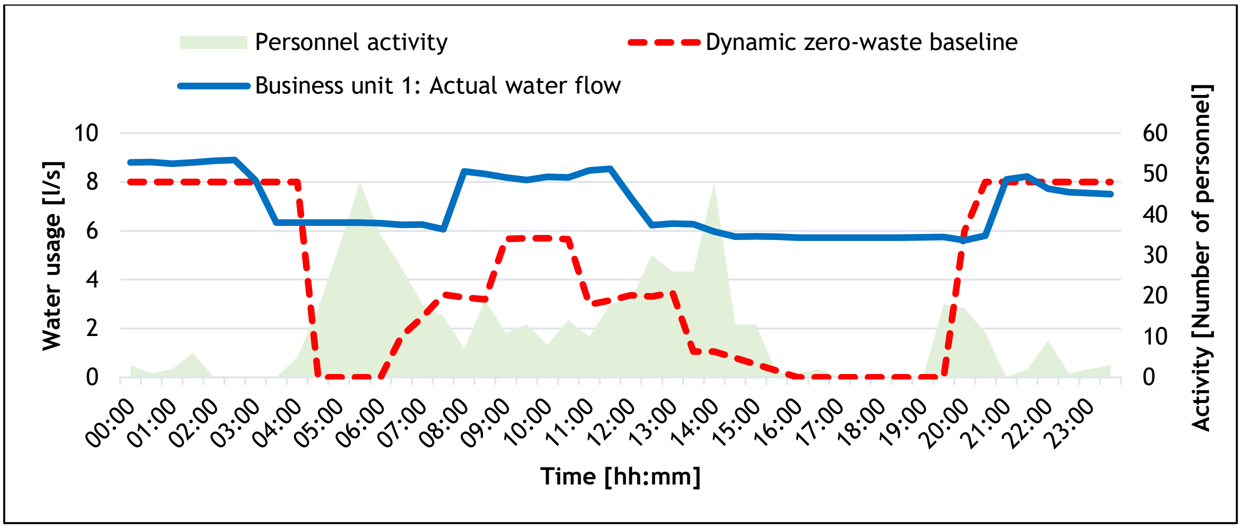

Figure 9: Business unit 1 pre-implementation results

These wastages, as seen in Figure 9, were identified using the developed method and attended to which resulted in the water being closed during periods when no water should be consumed (during shift changes and non-entry periods). This is seen in the post-implementation results shown in Figure 10. However, water is still wasted when personnel are working which requires attention.

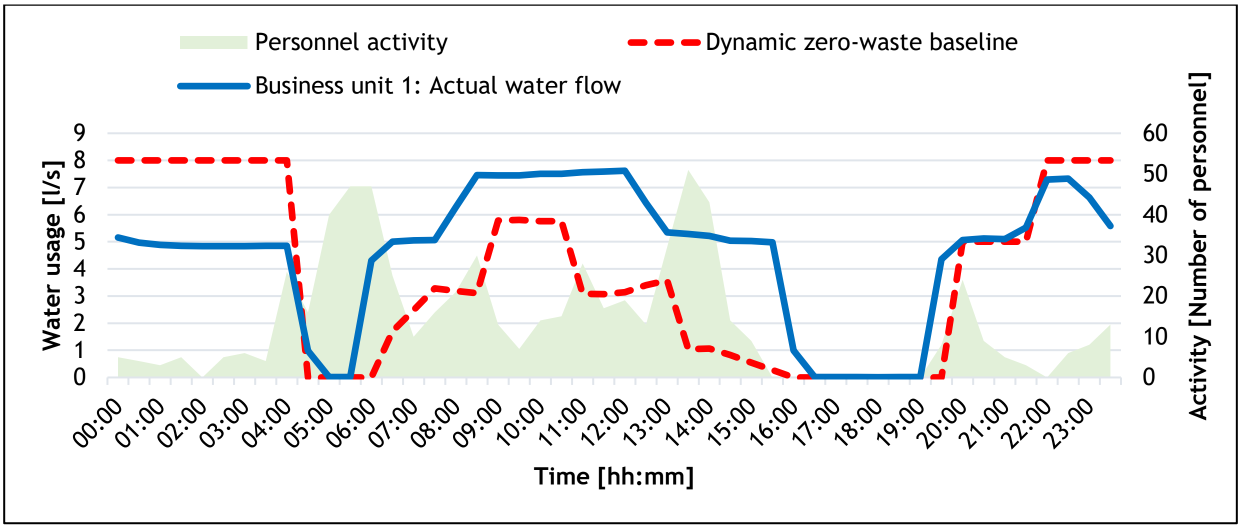

Figure 10: Business unit 1 post-implementation results

After an audit conducted based on the findings showed in Figure 9 and Figure 10, wastages seen has been attributed to 25 mm open hoses, waterjet guns that are left open and general leaks as depicted in Figure 11.

Figure 11: Identified inefficiencies on Business unit 1[1]

The mine pumping- and refrigeration correlation factors was determined by using equation (**2.** These correlations are displayed in Table 4.

Table 4: Mine X pumping- and refrigeration correlation factors

System	Correlation [kW/l/s]	Comment
Refrigeration	9.59	kW to cool 1 l/s to 4°C
Pumping	11.16	kW to pump 1 l/s

This information, together with the electricity tariffs were used to estimate the cost implications for the pre- and post-implementation results (actuals compared to baselines for each scenario). For Business unit 1, the daily water and energy wastage can be seen in Table

[1] Personnel photos taken during underground audit.

5. From this, it is clear that the wastages were reduced from the pre-implementation to the post-implementation.

Table 5: Pre- vs post-implementation daily wastages for Business unit 1

	Water wastage [l/day]	Pumping energy cost wastage [R/day]	Refrigeration energy cost wastage [R/day]	Total energy cost wastage [R/day]
Pre-implementation	264 041	R2 580	R2 217	R4 797
Post-implementation	72 811	R656	R611	R1 267
Savings	191 229	R1 924	R1 606	R3 530

This equates to an annual benefit of approximately R2.9 million for Business unit 1. The return-on-investment of the flow- and pressures meters for this specific business unit was calculated as 1 month.

The results from all the implemented business units were extrapolated to determine the average combined annual pumping- and refrigeration energy cost benefit for Mine X as seen in Table 6.

Table 6: Mine X average energy cost benefits (combined business units)

Average business unit daily energy saving [R]	R1 550
Level daily energy saving [R]	R26 350
Level annual energy saving [R]	R6 300 000
Mine X annual energy saving [R]	R19 100 000

3.4 Verification and Validation

The developed method was implemented on Mine X. The success of the method will be determined by performing the verification and validation step using the identified criterion.

By comparing the outcomes of the implemented method to the objectives thereof, the verification will be completed. The outcomes and objectives are summarised below.

- Objective: Development and implementation of dynamic zero-waste baselines.
- Outcome: Dynamic zero-waste baselines were developed and implemented on Mine X.

- Objective: Inefficiency detection and continuous monitoring for sustainability.
- Outcome: By using the developed dynamic zero-waste baselines together with the installed flow- and pressure meters, wastage was identified as seen in the pre- and post-implementation results.

- Objective: Energy- and water savings through inefficiency identification and rectification.
- Outcome: Energy- and water savings was achieved through the implementation of this method. For Business unit 1, a daily energy cost saving of R3 530 (191 Ml of water) was achieved. The data from all business units was extrapolated to determine the energy cost saving for Mine X. This resulted in an annual benefit of approximately R19 million.

For the validation of the method, the identified KPIs were compared to the outcomes.

- KPI: Pumping- and refrigeration consumption
- Outcome: A combined daily pumping- and refrigeration energy reduction of 2 240 kWh was achieved on Business unit 1. The extrapolated benefit on Mine X was calculated as 12 100 MWh.

- KPI: Water consumption
- Outcome: 191 Ml daily water reduction has been achieved on Business unit 1.

The method can be deemed successful as the criterion for the verification and validation has been met.

4 CONCLUSION

Over the past nine years, the operational costs of gold mining operations in South Africa have witnessed a significant increase of 54%. Extensive analysis has revealed that inefficiencies in services play a pivotal role in driving these escalating costs. Consequently, the exploration of inefficiency detection, particularly in localised areas near the working sites, has emerged as a pressing need.

To address this challenge, flow- and pressure sensors were strategically installed in three designated underground working areas, each delineated as a separate business unit. Dynamic zero-waste baselines were developed and employed to each business unit, which factor in multiple pertinent variables to accurately determine the required water quantities.

Through the implementation of the developed method, an annual energy cost saving of approximately R19 million was achieved for Mine X. The developed method has been deemed successful through the verification and validation thereof.

Moving forward, the developed method can be used to develop an accountability methodology to ensure the appropriate stakeholders are held responsible. It is anticipated that the implementation of this accountability framework will effectively prevent the occurrence of additional costs. By establishing clear lines of responsibility and fostering a culture of accountability, the mining operations can sustainably avoid unnecessary expenses and optimise resource utilisation.

ABSTRACT

Access to medical evaluation refers to the ability of individuals to receive timely and comprehensive medical assessments and evaluations for their health concerns. This process is critical for the accurate diagnosis, treatment, and management of medical conditions. However, access to medical evaluation can be affected by a range of factors. This paper aims to explore these factors by means of a systematic literature review. From this review various factors emerged, including geographic location, socioeconomic status, and the availability of healthcare resources. These factors can create disparities in access to medical evaluation, resulting in some individuals having limited or no access to medical services, which can have serious consequences for their health outcomes. By understanding these factors, future research can bridge the gaps. Thereby, ensuring that individuals have equitable access to medical evaluation is essential for promoting good health and improving health outcomes for all members of society.

Keywords: Access, medical evaluation, healthcare, innovative healthcare technology, improving health

1 INTRODUCTION

South Africa has a complex and fragmented public healthcare system, which faces numerous challenges. According to a study by Erasmus et. al [1], access to healthcare services in South Africa is impeded by various factors, including socio-economic factors, a shortage of healthcare providers, inadequate infrastructure, and the burden of communicable and non-communicable diseases.

The country's healthcare system is divided into two main sectors: the public sector, which is funded and managed by the government, and the private sector, which is funded by private health insurance schemes and out-of-pocket payments. However, most of the population relies on the public sector for healthcare services.

Several studies have highlighted the challenges facing the public healthcare sector in South Africa. For instance, a study by Hasumi and Jacobsen [2] found that poor quality of care and long waiting times were common complaints among patients in public healthcare facilities. Additionally, the shortage of healthcare workers, including doctors, nurses, and pharmacists, has been identified as a major challenge in the public healthcare sector [3].

Overall, the public healthcare industry in South Africa faces significant challenges, but there are ongoing efforts to address these challenges through policy interventions and innovative healthcare service delivery models.

The purpose of this paper is to investigate the factors that influence access to medical evaluation, specifically focusing on the South African healthcare context. By conducting a systematic literature review, the paper aims to identify and analyse the various factors that hinder individuals from receiving timely and comprehensive medical assessments and evaluations for their health concerns.

2 RESEARCH METHOD

To achieve the research aim, a systematic literature review (SLR) was conducted using a scoping approach to explore the scopes and purpose of various studies and frameworks. The study used Albliwi et. al.'s [4] proposed SLR method, which involved the following steps: Bullets:

- **Step 1**: Developing research purpose.
- **Step 2**: Creating research protocol.
- **Step 3:** Establishing relevance criteria.
- **Step 4:** Searching and retrieving literature.
- **Step 5:** Selecting studies using inclusion and exclusion criteria.
- **Step 6:** Assessing the quality of relevant studies.
- **Step 7:** Extracting relevant information from the papers.
- **Step 8:** Analyse and synthesize the data to identify themes and patterns.
- **Step 9:** Report the review in detailed results.
- **Step 10:** Disseminate the SLR by publishing a research paper.

Steps 1 to 6 outcomes are discussed in the sub-sections, while the findings of the study are documented under the findings section. Steps 9 and 10 are addressed by publishing the research paper.

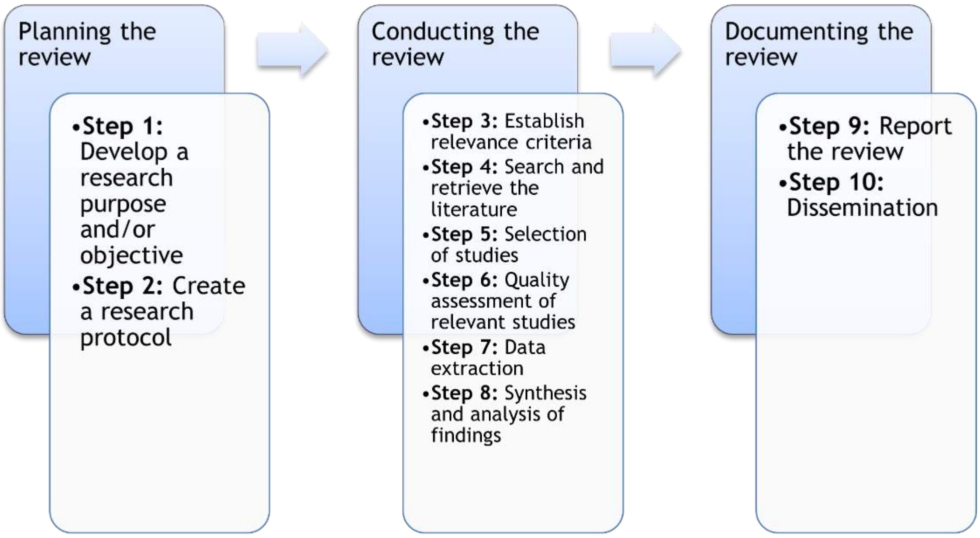

Figure 1: Research method (Adapted from [4])

2.1 Step 1: Develop a research purpose and/or objective

The purpose is to investigate the various factors that hinder individuals from receiving timely and comprehensive medical assessments and evaluations for their health concerns.

2.2 Step 2: Create a research protocol

Table 1 captures the research protocol with specific detail on the purpose, selection criteria, databases, keywords, and quality assessment criteria.

Table 1: Research review protocol (Structure adapted from [5])

Purpose of the study	To investigate the issues of poor healthcare access in South Africa
Inclusion Criteria	▪ South African based literature ▪ Literature discussing "medical evaluation", "diagnosis" and "access issues" ▪ Literature between the years 2012 – 2022
Exclusion Criteria	▪ Literature discussing private healthcare. ▪ Non-English literature ▪ Literature based in other countries (not in SA) ▪ Books, magazines, and reports
Search Databases	▪ Science Direct ▪ Scopus ▪ IEEE Explore ▪ Web of Science ▪ Emerald Insight Journals
Keywords	"South Africa" AND "Healthcare" AND "Issues"
Quality assessment criteria	• All duplicate literature must be removed. • Recovered literature checked for relevance. • Unjustifiably small sample size

	• Lack of supporting resources • Unclear scope and context • Unanswered research question • Lack of credibility, reliability, and validity

2.3 Step 3: Establish relevance criteria

When establishing the relevance criteria, it was important to be specific, but to leave room for as many studies to be included as possible [4] [5]. Thus, the following relevance criteria was developed by which studies were included:

- Literature that contained "Healthcare" and "Access" and "Issues" in the title, keywords or abstract of the study.
- Studies that are based in South Africa
- Discuss issues around access to medical evaluation.
- Literature between the years 2012 – 2022

2.4 Step 4: Search and retrieve the literature

The searching and retrieving of the literature were initially done using the databases stated in section 2.2. To initiate the search, the keywords were used to capture literature that addresses the issues of poor healthcare access in South Africa.

The search was conducted in selected databases and these databases were chosen due to their extensive coverage of scholarly literature and their relevance to the research topic. The keywords were applied in the title, keywords, and abstract fields of the literature to narrow down the search results.

The search was limited to studies published between the years 2012 and 2022 to ensure the inclusion of recent and relevant literature. This time frame allowed for an assessment of healthcare access issues in South Africa over the past decade.

Upon executing the search, the results from each database were recorded, noting the number of resources found in each database. These resources were retrieved in the form of articles or documents, which were saved for further evaluation in the subsequent steps of the SLR. This yielded a total of 9 900 studies.

The retrieved 9 900 resources then underwent a thorough screening process based on predefined inclusion and exclusion criteria. The inclusion criteria involved studies that were South African based, discussed healthcare access issues, and focused on medical evaluation. Conversely, literature discussing private healthcare, non-English literature, studies conducted in countries other than South Africa, and books were excluded from the review.

During the screening process, each paper underwent a rigorous evaluation of its title and abstract to assess its potential relevance to the research objectives. Papers that did not align with the criteria were excluded. A substantial portion of the excluded papers focused on general issues in South Africa's healthcare system without specifically addressing the issues surrounding access to medical evaluation. These papers explored topics such as economic factors influencing healthcare and strategies for improving overall healthcare quality. While valuable in their own right, they did not directly address the targeted focus of the systematic literature review on healthcare access issues.

The screening process involved reviewing titles, abstracts, and full texts of the resources to determine their eligibility for inclusion in the SLR, of which 22 resources met the criteria.

Duplicate resources were identified and removed to ensure that each study was considered only once in the subsequent analysis.

After completing the screening process, 20 remaining resources met the inclusion criteria were selected for the systematic literature review.

2.5 Step 5: Selection of studies

After applying the protocol outlined in step 1, a total of 22 studies were chosen from the initial screening process. These selected studies underwent further evaluation to eliminate any duplicate entries, resulting in 21 studies that met the criteria for inclusion. The selection process and its results are depicted in Figure 2, specifically in the "Screening" and "Eligibility" sections, which provide an overview of the search results for each database. Following the study selection, relevant information for each study, including author names, study titles, and publication years, was recorded.

2.6 Step 6: Quality assessment of relevant studies

Once the removal of duplicates was completed, a thorough assessment of the studies' quality was conducted by examining their full texts. The evaluation criteria included factors such as sample size, availability of supporting resources, scope and content of the studies, research questions addressed, as well as their reliability, credibility, and validity. Remarkably, all 21 papers met the criteria for inclusion and were deemed acceptable.

Figure 2 comprehensively documents steps 4 to 6 of the selection process, as outlined in sections 2.4 to 2.6. The figure depicts the various stages of the search on the left side and provides a clear distinction between the number of studies initially found and the number ultimately selected from each database.

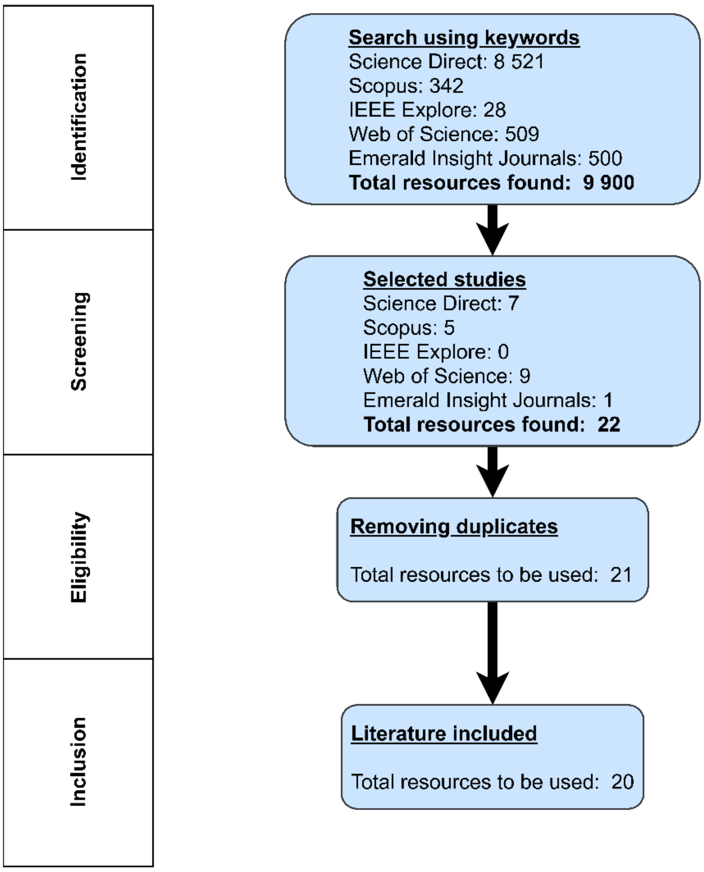

Figure 2: Selection Process

3 FINDINGS

3.1 Step 7: Data Extraction

After selecting the studies and reviewing their full texts, a summary was compiled to outline the healthcare access issues addressed in each study. This summary is presented in Table 2, which provides information such as (1) the provincial location of each study, (2) the factors influencing healthcare access, (3) the primary barriers identified, and (4) the population group affected. Additionally, Table 2 includes details about the authors, year of publication, and research titles to provide a complete overview of the included studies.

#	Author(s)	Year	Research Title	Issue addressed	Provincial Location	Affecting Factors	Main barrier to healthcare access	Population group	Ref

3.2 Step 8: Synthesis and Analysis

3.2.1 Provincial Location

From the analysis, the studies were evaluated based on their geographical location within South Africa. Figure 3 illustrates the data distribution of various provinces in South Africa, with a notable emphasis on the Eastern Cape, KwaZulu-Natal, and Mpumalanga provinces. Notably, the provinces of Eastern Cape and KwaZulu-Natal emerged as areas with a significant representation of studies. These provinces are known to have higher levels of poverty and socio-economic challenges compared to other regions in the country. The graph includes a category labelled "South Africa" to represent the studies that did not specify a specific province where they were conducted. This distribution provides a diverse and comprehensive view of healthcare access issues in different regions of the country, contributing to a more comprehensive understanding of the overall landscape of poor healthcare access in South Africa.

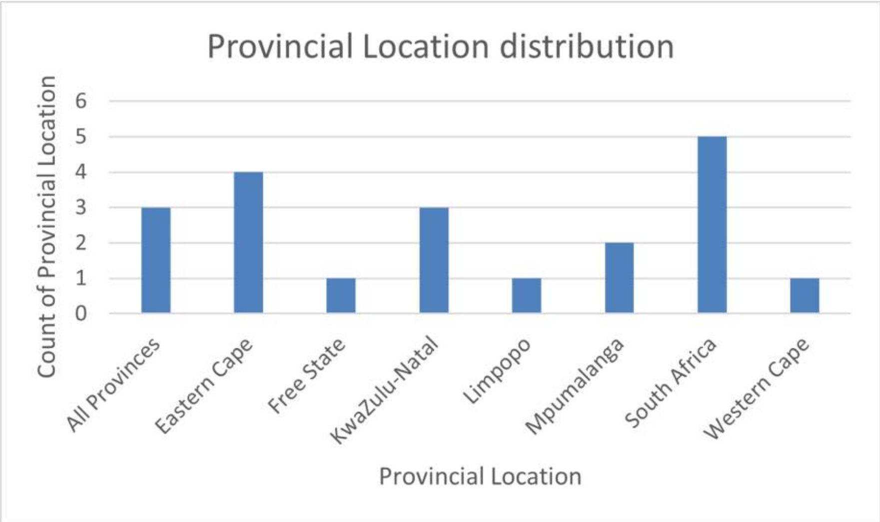

Figure 3: Bar graph of Provincial Location distribution

3.2.2 Population Groups

The data indicates the distribution of studies included in the review based on the population groups they focused on. The population groups considered include diagnosed disease or illness, health workforce, low-income group, marginalized group, older children and adolescents, people with disabilities, and rural populations. The number of studies conducted on each population group is provided in Figure 4.

The inclusion of two studies on individuals with diagnosed diseases or illnesses indicates a focus on understanding the healthcare access challenges faced by individuals already diagnosed with specific medical conditions. The seven studies on the health workforce shed light on the barriers and challenges encountered by healthcare providers, including healthcare professionals, workers, and support personnel, in accessing and delivering healthcare services.

Furthermore, the SLR included four studies dedicated to exploring healthcare access issues faced by low-income groups, highlighting the challenges experienced by individuals with limited financial resources. One study specifically focused on marginalized populations, aiming to understand the healthcare access issues faced by socially, economically, or politically marginalized groups.

Additionally, the SLR addressed the healthcare access issues experienced by older children and adolescents through one study. Two studies focused on people with disabilities, aiming to identify the barriers and challenges they encounter in accessing healthcare services. Lastly, three studies investigated healthcare access issues in rural areas, highlighting the unique challenges faced by individuals residing in remote or underserved rural communities.

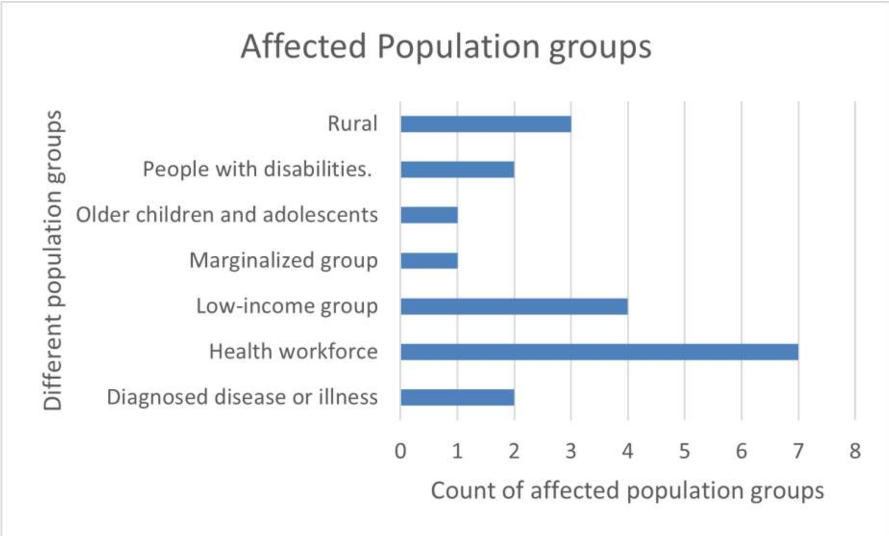

Figure 4: Affected Population groups distribution

3.2.3 Barriers to healthcare access

The barriers represent key factors that impede individuals from accessing healthcare services. Understanding and analysing these barriers is crucial for identifying gaps and challenges in healthcare access.

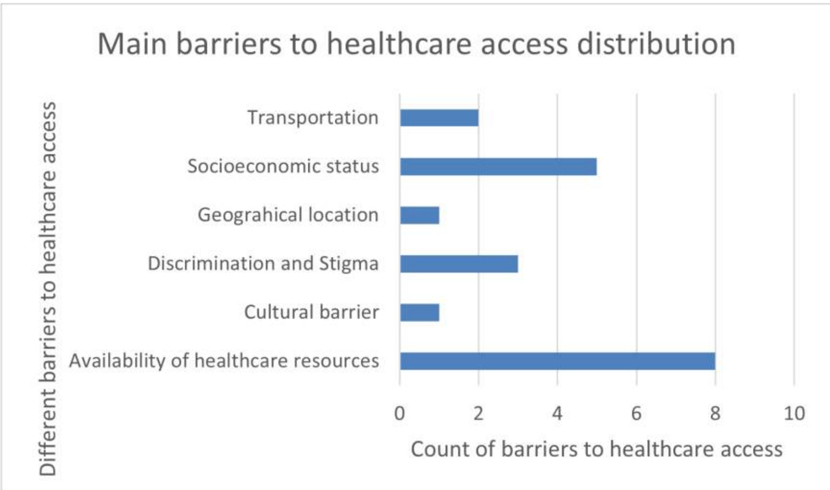

Figure 5: Barriers to healthcare access distribution

As illustrated in Figure 5, the most prevalent barrier identified in the data is the availability of healthcare resources. This suggests that inadequate availability of healthcare facilities, medical equipment, and healthcare professionals poses a significant challenge to accessing healthcare services. This finding emphasizes the need to address resource limitations and ensure sufficient healthcare infrastructure.

The presence of cultural barriers, exemplified by the resistance of certain communities to provide assistance to asylum seekers, highlights the influence of cultural attitudes and prejudices on healthcare access. This finding underscores the importance of addressing misconceptions and promoting inclusivity and empathy within society.

Discrimination and stigma emerge as barriers to healthcare access. This suggests that discrimination based on factors such as race, ethnicity, gender, or health conditions, as well as the stigma associated with certain illnesses, can deter individuals from seeking and receiving adequate healthcare. Recognizing and addressing discrimination and stigma are crucial steps towards fostering equitable and inclusive healthcare systems.

Geographical location points to the impact of physical distance and remote locations on healthcare access. It underscores the challenges faced by individuals residing in geographically isolated areas, where accessing healthcare services may be hindered by limited infrastructure, transportation options, or healthcare providers.

Socioeconomic status emphasizes the influence of economic factors on healthcare access. Individuals with lower socioeconomic status may face financial constraints, lack of health insurance, or limited resources, making it difficult for them to access necessary healthcare services. Addressing socioeconomic disparities is essential for promoting equitable access to healthcare.

Transportation signifies the role of transportation barriers in healthcare access. Difficulties in reaching healthcare facilities due to limited transportation options, especially in rural or underserved areas, can impede timely access to care. This is particularly relevant in South Africa, where a majority of the population relies on public transportation as their primary mode of commuting.

4 REPRESENTATION OF FINDINGS

The outcome the SLR illustrates the wide array of challenges that South African's face when it comes to accessing medical care. Figure 6 captures the summary of these challenges.

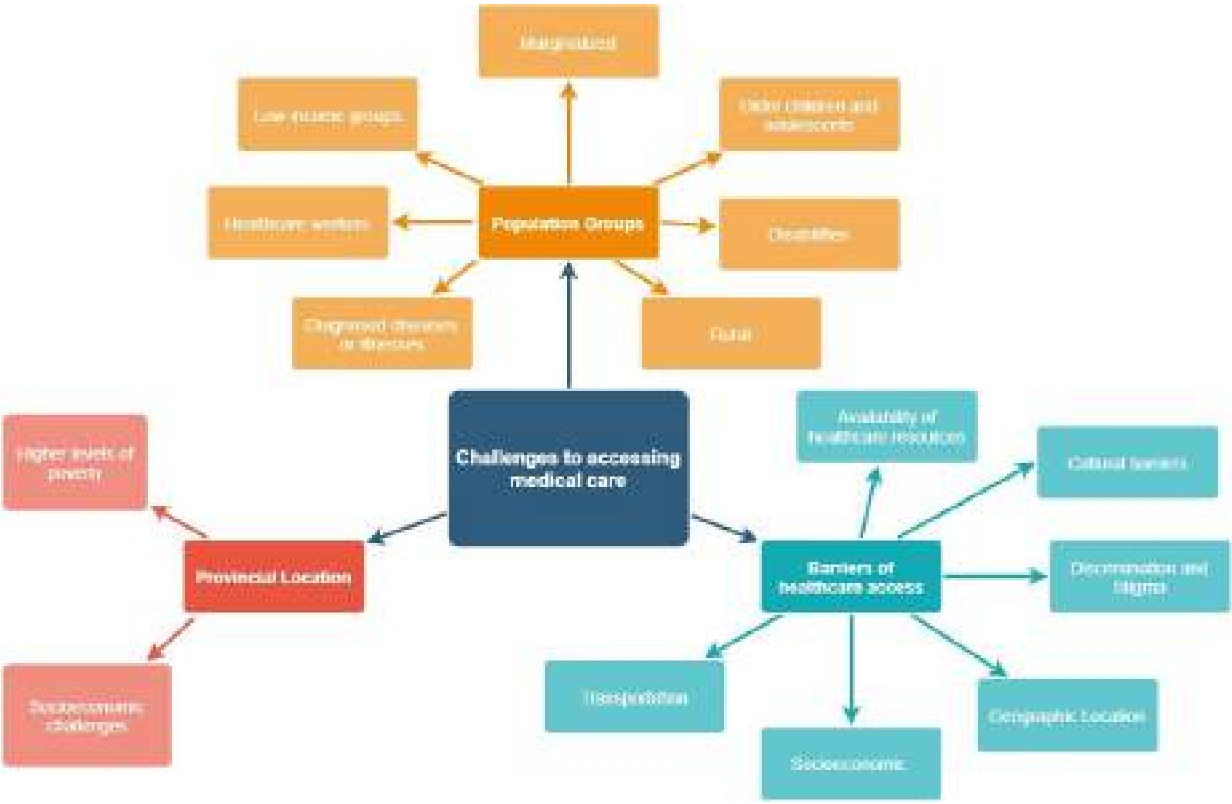

Figure 6: Representation of findings

5 CONCLUSIONS AND RECOMMENDATIONS

This study sought to look into the problems of South Africa's limited access to healthcare. The outcomes were displayed in tabulated analysis.

Using an approach adopted from Albliwi et al. [4], a systematic literature review was conducted to achieve the goal. The investigations were based on the review process, and the findings may help researchers comprehend the problems relating to South Africa's limited access to healthcare.

Based on the findings of the literature review, a few recommendations can be made to improve the situation. Firstly, it is crucial to address the availability of healthcare resources. Increasing the number of healthcare facilities, ensuring adequate staffing, and equipping them with the necessary resources will help meet the healthcare demands of the population.

Another important recommendation is to enhance cultural competency among healthcare providers. Implementing cultural competency training programs will enable them to better understand and respect diverse cultural norms, beliefs, and practices. Discrimination and stigma were identified as significant barriers to healthcare access. To address this, it is recommended to implement anti-discrimination policies and raise awareness through campaigns. Creating an environment that promotes equitable access to healthcare without fear of discrimination or judgment is essential. Socioeconomic disparities have a considerable impact on healthcare access. Strategies should be developed to address financial constraints, lack of health insurance, and limited resources.

Transportation barriers, especially in rural and underserved areas, pose challenges in accessing healthcare services. It is recommended to enhance transportation options by improving infrastructure and services. Strengthening primary healthcare will bring comprehensive and accessible healthcare closer to where people live, reducing the need for long-distance travel.

While this study provided a fulsome analysis of the challenges available in literature, it is recommended that future research work on addressing some of these challenges in a comprehensive way.

By designing a comprehensive mobile application, this design idea leverages the widespread use of smartphones to provide accessible and convenient healthcare services. The application addresses key challenges identified in the study, including resource availability, cultural sensitivity, discrimination, socioeconomic disparities, transportation barriers, and the promotion of primary healthcare. It aims to bridge the gap between individuals and healthcare services, facilitating better access to healthcare and ultimately improving healthcare outcomes in South Africa.

In conclusion, the outcomes of this study shed light on the complex issues surrounding limited healthcare access in South Africa. While the presented recommendations provide valuable insights, they represent just the beginning of a journey towards equitable healthcare for all. It is evident that further research is needed to delve deeper into these challenges, develop innovative solutions, and create strategies for implementation.

ABSTRACT

The primary sector includes the agricultural, forestry, and fishing industries. For South Africa's economy, these industries are considered key sectors as StatsSA indicates a joint increase of 15.9% through the 3rd and 4th Quarters of 2022. In a similar vein, Statista explained that the market value of precision farming is expected to grow from approximately 7 billion to 14.5 billion U.S. dollars from 2021 to 2027. Despite the success of precision farming, there is limited research on farm management support systems in Sub-Saharan Africa, suggesting a major research gap. Therefore, this paper aims to conduct a systematic literature review (SLR) to investigate studies that pertain to precision agriculture applied in the swine industry. This research showcases themes such as the affiliated countries of identified studies, the distribution of studies, technologies and strategies used by researchers, and experienced enablers and barriers of implemented precision agriculture solutions.

Keywords: Precision farming, Swine industry, systematic literature review

[*] Corresponding Author

1 INTRODUCTION

The primary sector includes the agricultural, forestry, and fishing industries that involve the production and trade of farmed crops, livestock, fish or food, and wood. For South Africa's economy, these industries are considered as key sectors as there was a joint increase of 15.9% through the 3rd and 4th Quarters of 2022 [1, 2]. In a similar vein, Statista explained that the market value of precision farming is expected to grow from approximately 7 billion to 14.5 billion U.S. dollars from 2021 to 2027 [3].

As agriculture has evolved over the past 50 years, recent use of techniques such as precision agriculture has emerged. Fuglie [4] defines precision agriculture as "the application of modern information technologies to provide, process and analyse multisource data of high spatial temporal resolution for decision making and operations in the management of crop production." This has been noted in various industries, which include agriculture, forestry, and fishing. In South Africa, the aforementioned industries planned to make use of precision agriculture. Buchana et al., [5] shows that, between 2016-2018, 52.9% of the agriculture industry, 18.3% of the forestry industry and 0% of the fishery industry makes use of precision agriculture.

Agriculture is considered as the largest industry in South Africa compared to forestry, and fishery industries. In 2017, animals and animal products made up 52% of the total South African agricultural income of which pigs were the third most sold animals [6].

Despite the success of precision agriculture, there is limited research on farm livestock management support systems in Sub-Saharan Africa, suggesting a major research gap [7]. This suggestion motivates the research to cast a larger initial focus by expanding to a global search before contextualizing the findings to Sub-Saharan Africa. Therefore, the aim of this paper is to conduct a systematic literature review (SLR) to investigate studies that pertain to precision agriculture applied in the swine industry.

This paper comprises of an overview on the methodology (section 2), followed by the results (found in Appendix A), findings (Section 3), and conclusions and recommendations (Section 4).

2 RESEARCH METHOD

For this study a systematic literature review (SLR) is conducted [8].Furthermore, this took the form of a scoping SLR, to allow for the investigation of available literature to scope and understand the current state of precision agriculture applied in the swine industry.

The sequence and grouping of the steps into research phases are captured in Figure 1, while the detail of each step is as follows:

- Step 1: Develop a research purpose and/or objective – Clearly state the goal of the SLR.
- Step 2: Develop research protocol – Create a research protocol that includes the purpose, inclusion criteria, exclusion criteria, databases, keywords and quality assessment criteria.
- Step 3: Establish relevance criteria – State the reasoning for if a resource is relevant to this study.
- Step 4: Search and retrieve the literature – Conduct searches on applicable scientific databases to find literature.
- Step 5: Selection of studies – Use the inclusion and exclusion criteria to select studies.
- Step 6: Quality assessment for relevant studies – Assess the quality of each paper.
- Step 7: Data extraction – Extract relevant information from the papers.
- Step 8: Analysis and synthesis of findings – Analyse and synthesise the data from the papers in order to find themes and patterns.

- Step 9: Report – Report the review in detailed results.
- Step 10: Dissemination – Publish the SLR

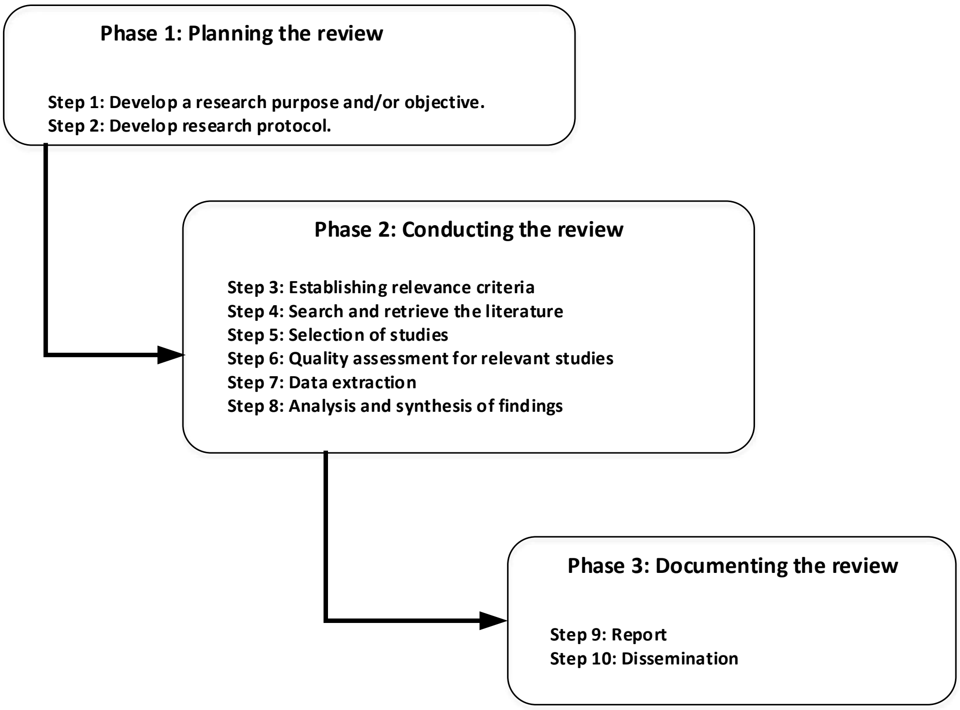

Figure 1: Research method for SLR (Adapted from [8])

2.1 Step 1: Develop a research purpose

The purpose of this research is to investigate studies on precision agriculture applied in the swine industry.

2.2 Step 2: Develop research protocol

The research protocol was developed and is shown in Table 1. The protocol breaks down the purpose, criteria, databases, keywords and quality assessment criteria.

Table 1. Research protocol

Purpose of the Study	To investigate studies on precision agriculture applied in the swine industry.
Inclusion Criteria	• Literature that contains "Precision", "farming", "agriculture", "Pig". • Time period for searched literature 2019-2023 • The explanation of techniques, tools, method, concepts in precision farming or agriculture is provided. • Information and communication management systems (ICM)
Exclusion Criteria	• Literature referring to other types farming. • Precision technology used in industries other than agriculture. • Non-English literature • Literature that relates to the advancement of technology

Search Databases	• Science Direct • Scopus • IEEE Explore • Web of Science • Emerald Insight Journals
Keywords	"Precision farming" OR "Precision agriculture" AND "Pig"
Quality assessment criteria	• All duplicate literature must be removed. • Negative results/findings are presented. • The conclusions are reliable and relate to the purpose of the study. • The aim or purpose of the study is clearly stated. • The overall methodology used is described in such a manner that the study can be replicated.

2.3 Step 3: Establish relevance criteria

The following relevance criteria was developed in order to screen studies for inclusion and exclusion:

- Inclusion criteria:
    - Literature that contains "Precision", "farming", "agriculture", "Pig".
    - Time period for searched literature 2019-2023
    - The explanation of techniques, tools, method, concepts in precision farming or agriculture is provided.
    - Information and communication management systems (ICM)
- Exclusion criteria:
    - Literature referring to other types farming.
    - Precision technology used in industries other than agriculture.
    - Non-English literature
    - Literature that relates to the advancement of technology

2.4 Step 4: Search and retrieve the literature

The search and retrieval of the literature was done on the databases captured in Table 1. The initial search yielded 431 studies. The search and retrieval process that was followed, is documented in the “Identification” section of Figure 2.

2.5 Step 5: Selection of studies

After reviewing the abstracts and titles of the studies 34 studies were deemed eligible for inclusion using the criteria stated in table 1. The outcome of the selection process is captured in the “Screening” and “Eligibility” sections of Figure 2.

2.6 Step 6: Quality assessment for relevant studies

After all duplicates were removed, the quality of the studies were assessed using the assessment criteria outlined in Table 1. Studies were selected for inclusion. A total of 34 studies were finally used. Figure 2 captures step 4 through to 6 of the selection process, as discussed in section 2.4 – 2.6 (refer to Figure 1).

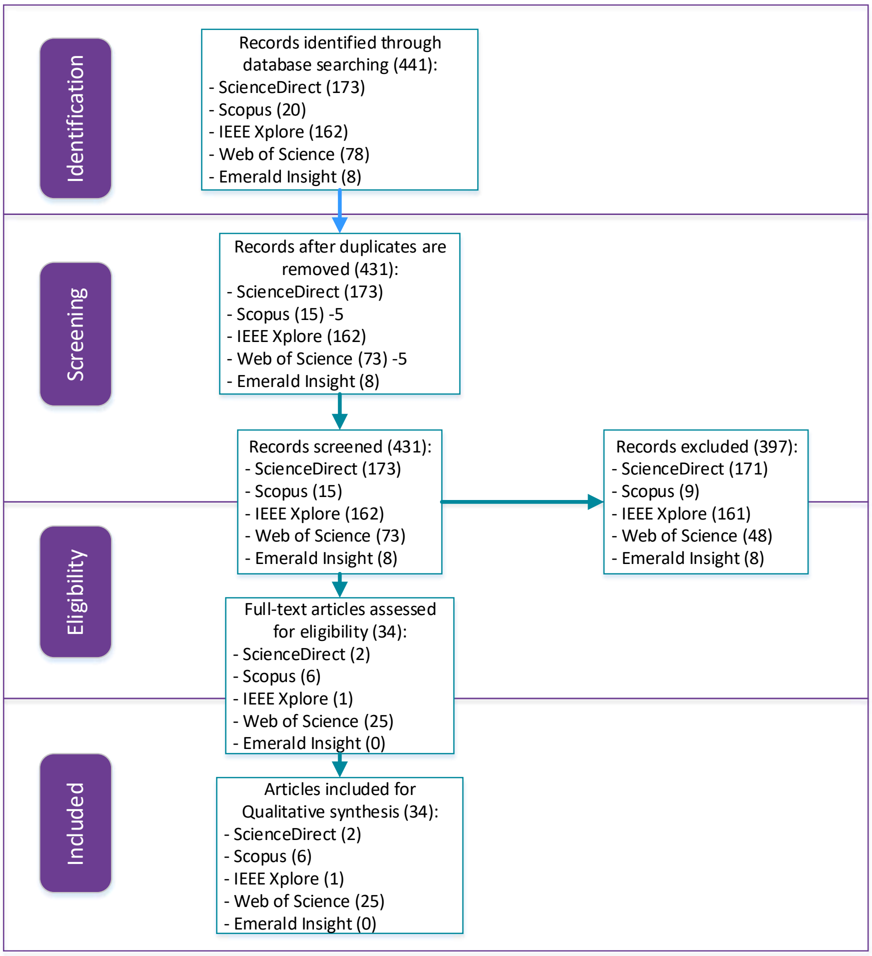

Figure 2. Systematic Literature Review (SLR) selection process chart

3 FINDINGS

The findings (step 7 and 8 in Figure 1) from the SLR methodology are discussed in the following sub-sections.

3.1 Step 7: Data extraction

After reviewing the literature a table was completed to capture and summarize technologies used, strategies/tools/techniques/methods/concepts, enablers and barriers to the implementation and use of the technology, as well as the core findings of the studies (Refer to Table 4 in Appendix A).

3.2 Step 8: Analysis and synthesis of findings

Using the research protocol described in Table 1, 34 publications were identified and used for analysis and synthesis. Findings include themes such as authors affiliated countries, distribution of publications per year, identified technologies, identified strategies, enablers, and barriers.

3.2.1 Authors affiliated countries of publication

Figure 3 illustrates a map distribution of authors' affiliated countries publications. Per continent, it was found that 10 studies are affiliated to North America, 10 to Europe, 17 to Asia, and 1 to Australia. More specifically, 13 studies are affiliated to China and 7 to the United States of America (USA). This suggests that China and USA are leaders in researching pig precision farming. Interestingly, no pig precision farming research has been found that is affiliated with Africa.

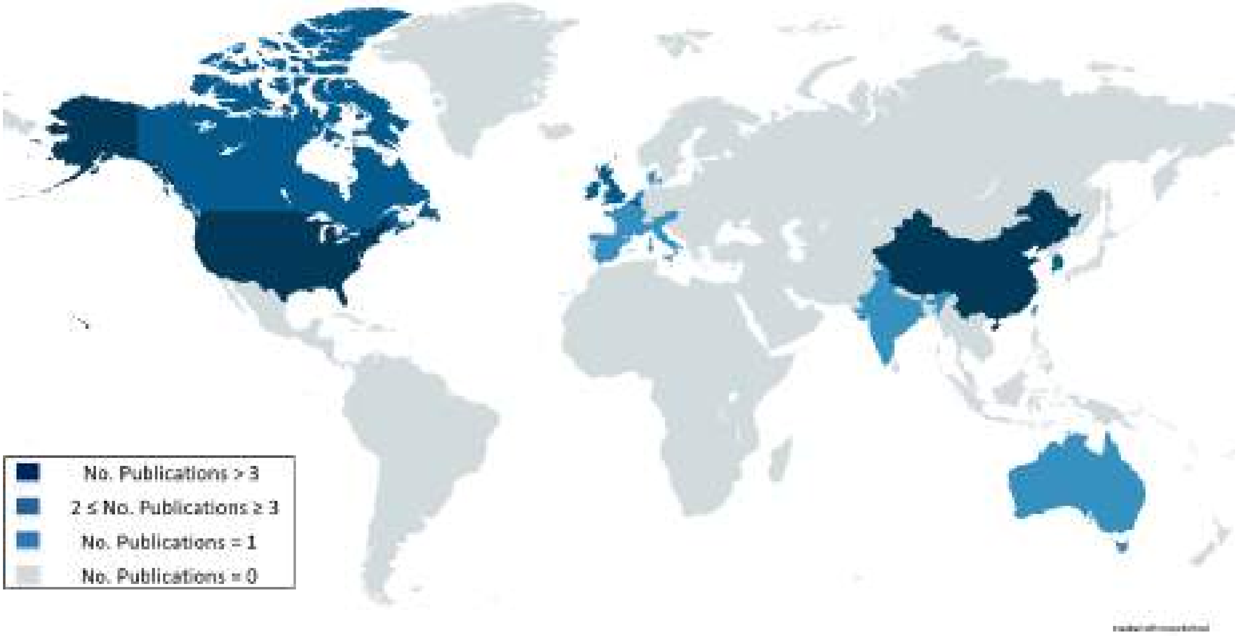

Figure 3: Map distribution of authors' affiliated countries of publication

China, The European Union, and USA are the top 3 global pork producers in 2022 and 2023 [9], which correlates with the map distribution of published research in pig precision agriculture techniques illustrated in Figure 3. It is important to note that given the research protocol (refer to Table 1), no studies were found within the South African context, specifically.

3.2.1.1 Distribution of Studies

Figure 4 illustrates the distribution of publications per year. Figure 4 illustrates that there is an increase of research in pig precision agriculture under the research protocol deployed the past 5 years. It is important to note that the low number of publications for 2023 is attributable to study being conducted in this year.

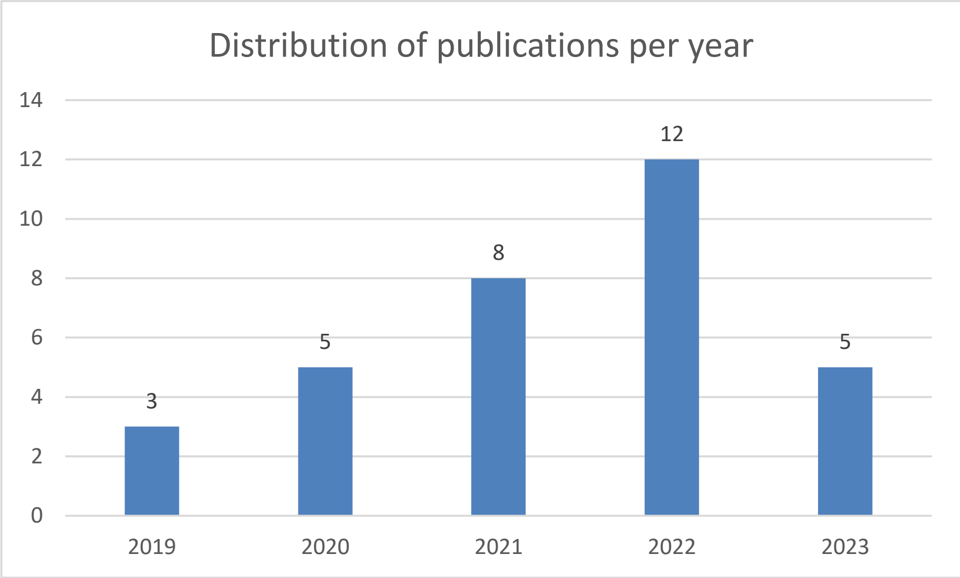

Figure 4. Studies published per year

This increase may suggest that there is an increase of interest in applying precision agriculture in the pig farming industry.

3.2.1.2 Identified Technologies

Table 2 includes brief descriptions of identified technologies. In general, the technologies involve the acquisition, processing, and analysis of data.

Table 2. Brief descriptions of identified technologies

Technologies	Brief Description
Thermal/infrared imagery	Infrared imagery is used to indicate pig growth efficiency, health and to improve pig identification.
Precision feed stations	Precision feed stations are used to indicate pig growth efficiency and to acquire data for relevant feed consumption indicators.
IoT systems	This technology involves the acquisition, management, and visualization of data for effective decision-making purposes.
Artificial Intelligence (AI)	AI is used for data analysis purposes and to improve pig detection.
Computer Vision systems (CVS)	CVS involves remote pig weighing and body weight prediction using camera recordings.
Deep learning software	Deep learning is a machine learning method that improves pig detection by analysing acquired data.
Coding Software	Coding software are platforms for development of data acquisition, and processing i.e., Matlab, RStudio, Visual Studio.

Sensors and Scanners	Several sensors and scanners are found in the SLR and are used to acquire data relevant to the purpose of the study i.e., humidity, temperature, motion, pressure, photoelectricity etc.
Cameras	Similar to sensors, cameras are used to acquire data that pertains to pig behaviour, health, and growth.
Qualtrics	In one of the studies, Qualtrics is used as a survey system,

Table 2 includes cutting edge technologies which suggests that precision agriculture gives rise to data driven farming. The implementation strategy of these technologies is discussed in Section 3.2.1.3. Furthermore, the enablers and barriers of implemented technologies are discussed in Section 3.2.1.4.

3.2.1.3 Strategies/tools/techniques/methods/concepts

Various strategies, tools, techniques, methods and concepts emerged from the literature. Table 3 includes a brief description of identified strategies.

Table 3. Brief description of identified strategies

Strategy	Brief description
Implementation of data acquisition technologies (Sensors, cameras etc.)	This involves the installation of software, sensors, cameras, and other equipment or technology used for the capturing of data. In some studies, specific pigs breeds and pig sizes were selected that meets the capacity of the technology used
The acquisition of data	The process of acquiring data occurs over a set period of time where pigs interact with technologies. This process presents the opportunity to determine the durability, effectivity, usability, and accuracy of the technology used
Pre-processing of data (i.e., data enhancement)	Pre-processing of data occurs when large sets of data have been acquired and requires filtering or, in the case of images, enhancement for algorithms or efficient datasets
Processing of data (i.e., Dataset creation)	The processing of data involves the dataset creation wherein pre-processed data is stored. The structure of the set is important as it determines the efficiency of the processing of the data.
Analysis of data (Using deep learning, AI, or other algorithms)	Data analysis involves analysing the acquired data to communicate a finding depending on the purpose of the research. Some studies analysed data using algorithms to determine which algorithm is considered more accurate, where some studies used deep learning to improve the technology's detection ability.
Visualization of analysed data	Visualization of analysed data involves graphs and tables with the purpose of conveying a finding of the methods or algorithms used.

Results of different scenarios are used for comparison and verification	Several studies applied a method in different scenarios and compared findings for verification purposes.

It is worth noting, a study's strategy involved infrared technology applied to four different pig age groups to determine if there is a differentiation in results [10]. Where a different study developed a CVS for the prediction of measurement variables and compared several algorithms to identify the most accurate predictor [11]. One study's strategy involved the processing of acquired data as an input for a nutritional model. The output of this nutritional model determines the nutrient requirements of an individual pig and instructions are communicated to automatic feeders [12].

These findings indicate the various utilization of techniques and technologies, coupled with the generalized strategy included in Table 3, to improve pig growth, behaviour, and health.

3.2.1.4 Enablers and barriers for the successful use of precision agriculture in Pig farming

Figure 5 illustrates identified enablers and barriers affecting pig precision agriculture. In summary, identified enablers involve utilizing technology to acquire, manage, and report data effectively and in a manner that is useful for decision making purposes. However, data inaccuracies, the impracticability of precision technologies, and farmer scepticism act as barriers to the adoption of pig precision agriculture. These barriers are further detailed in Appendix A relevant to the study.

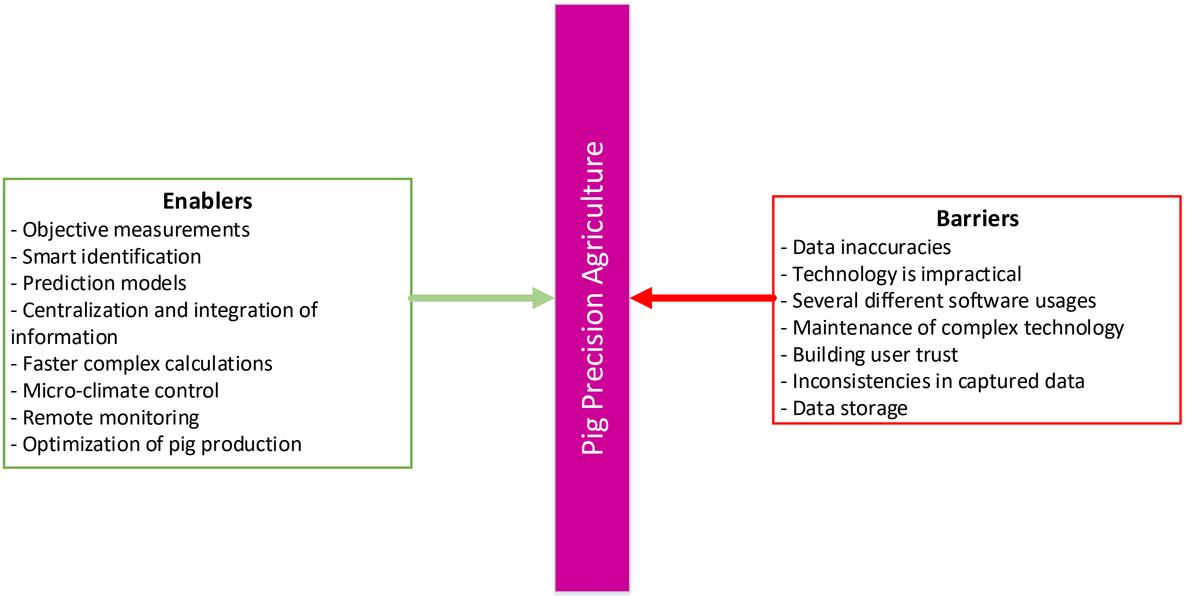

Figure 5. Identified Enalers and Barries for Pig precision agriculture

One study found that developed countries have the ability to invest in agricultural research and development projects where developing countries do not. This barrier for developing countries may serve as a reason for lack of published research in Africa (refer to Section 0).

4 CONCLUSIONS AND RECOMMENDATIONS

This paper conducted a systematic literature review (SLR) to investigate studies that pertain to precision agriculture applied in the swine industry. It was found that China, the Europe, and the USA are leaders in researching pig precision farming which is understandable as these leaders are the top 3 global pork producers. Moreover, there is a growing interest of research in pig precision agriculture the past five years which suggests the increase of pig precision agriculture technique applications.

The SLR finds numerous technologies that are used for acquiring, processing, and analysing data. The technologies integrate with strategies used by researchers which involves the implementation of these technologies, the management and analysis of acquired data, and visualization of analysed data for discussion purposes. Discussions included enablers and barriers experienced by researchers where it was found that precision agriculture technologies assist farm operations to be done remotely, and automatically. However, failure of adoption remains a barrier due to events such as data inaccuracies, impractical technology, farmer scepticism and more.

Although IoT technologies bear several benefits for pig farmers, to mitigate the barrier of failed adoption, further research in technology usability and data accuracy is required in the technological development space of IoT to implement and realise benefits in pig farming operations.

The research synthesis shows that there is a growing interest in pig precision agriculture which agrees with the trend of the growing precision agriculture market. However, this study did not find relevant published articles that are affiliated to South Africa, or Africa, indicating a research gap in the research of pig precision farming. Yet, a barrier that South Africa may face is the lack of investment in agricultural research and development projects. Pig precision agriculture can be seen as valuable for South Africa due to the growing pork production market due to the benefits it has, but for efficient implementation further research, and investment in research and development projects may be needed.

It is recommended that investigation into the application of IoT in the administrative space of pig precision agriculture is explored. In addition, it is recommended to investigate the impact of IoT on the pig value chain.

This study highlighted the growing global interest of pig precision agriculture and the research involved in the implementation of IoT systems on pig farms. Pig farmers consider several variables that influence decision making and IoT enables the integration of these puzzle pieces to build the larger narrative. Effective decision making will have a ripple effect, improving the larger and more complex puzzle of an inefficient value chain. The study contributes one piece to the puzzle of the implementation of precision agriculture techniques.

APPENDIX A

Table 4. Data extracted from applicable studies

#	Author(s)	Year	Country	Title	Technologies	Strategies/tools/techniques/methods/concepts	Enablers (success)	Barriers (failure)	Core finding	ref
1	Shi Shuaia, Yin Linga, Liang Shihao, Zhong Haojie, Tian Xuhong, Liu Caixing, Sun Aidong, Liu Hanxing	2020	China	Research on 3D surface reconstruction and body size measurement of pigs based on multi-view RGB-D cameras	Thermal imaging	Measuring of pig size using a low-cost depth camera. 3D point cloud acquisition. Point clouds pre-processing and registration. Feature extraction and body size measurement.	Provides a method for objective measurement of pig size.	Data acquisition had missing data due to environmental conditions i.e., railings and pig behaviour. The technology is unfriendly to ordinary workers and needs a specialized worker for installation and maintenance.	The method used improves registration precision and increases the accuracy in the curve-fitting.	[13]
2	A.L.Schaefer , O. Iheshiulor, H. von Gaza, P. Charagu, G. Simpson, A. Huisman	2023	Canada	Thermal Profiles: Novel phenotypic measurements of animal growth and metabolic efficiency	Infrared thermography Infrared thermal scanner Nedap feed station technology Google cloud Microsoft Access MedCalc	Feed station technology and infrared thermography are used to indicate pig growth efficiency in a controlled environment.	The technological results present a correlation between animal performance and thermal biometrics. Assists in identifying top performing pigs thus channelling feed costs effectively.	The method is not useful for mid test weights for removing animals from feed stations is disruptive and stressful for the animal, negatively affecting their growth.	The results indicate that the tool is useful for reducing cost of production and greenhouse gas impact.	[14]
3	Stephan Rosengart,	2022	Germany	Characteristics of thermal	Infrared thermography	Infrared thermography of the mammary gland	The technology used does help	Using the warmest pixel	Infrared thermography	[10]

The method is applied to four different parities to determine whether there would be differentiation between PDS-affected and non PDS-affected sows or not.	identifying diseased sows.	offers a risk of inaccuracies.	coupled with precision livestock farming and smart farming can provide the tool to detect old diseased sows earlier which will assist in better piglet feeding and improved animal health.	
4	Arthur F. A. Fernandes, João R. R. Dórea, Bruno Doura do Valente, Robert Fitzgerald, William Herring, and Guilherme J. M. Rosa	2020	United States of America	Comparison of data analytics strategies in computer vision systems to predict pig body composition traits from 3D images	Computer vision systems (CVS) Elastic networks Artificial neural networks Deep learning image encoder Matlab, R, EziWeigh5i, Python, TensorFlow,	The approach involves firstly, the development of CVS for prediction of body weight, muscle depth, and back fat from top view 3D images of pigs. Secondly, the comparison of predictive approaches such as multiple linear regression, partial least squares, and machine learning techniques.	3D imaging enables easier image processing and removal of background. Results show that CVS improves the prediction of body composition in live finishing pigs.	At least three different predictive models would need to be deployed to apply the study's models in the field.	The study demonstrates the possibility to predict muscle depth and back fat with CVS in an automated setting using 3D images from farm conditions, without needing to pre-process images.	[11]
5	Zhiwei Hu, Hua Yang, Tiantian Lou, Hongwen Yan	2023	China	Concurrent channel and spatial attention in Fully Convolutional Network for individual pig image segmentation	Ubuntu 16.04, 16GB Tesla V100 GPU, Adam, ImageNet, MobileNetV2, VGC16, ResNet50, ResNext50, UNet, LinkNet, FPN, PSPNet	The most suitable encoder-decoder combination is identified through evaluating several encoder and decoder structures. A novel model that combines channel with	The method used improves the distinguishing of the pig area from the background and the outline of the pig is clearer in captured images.	While the study was conducted, it was found that debris, light intensity, and grouped pigs provide challenges for accurate segmentation.	The study shows that concurrent channel and spatial attention can capture contextual information effectively resulting in	[15]

						spatial attention information is proposed. The model is implemented on an individual animal and then to a grouped pig environment. The results of implementation in different scenarios is used as verification.			performance gains. The study found that spatial attention is more effective than channel attention. The study's model can be moved to complex scenarios	
6	Rachel Schambow, Yoder Colin, Wright Dave, Daniella N. Schettino, and Andres M. Perez	2022	United States of America	Enhancing passive surveillance for African swine fever detection on U.S. swine farms	Qualtrics	The study characterized regularly collected swine data and disease surveillance activities. It then explored how characterized activities can be used for ASF surveillance. Lastly, it identified how advancing swine industry technologies and initiatives for disease preparation could be used to improve ASF surveillance.	The study found that management software usage is high across all farm types in the U.S which can facilitate API connections, smart phone devices, and the uploading of a centralized management software.	Software usage varied greatly which may hinder the development of a uniform, data-monitoring EPS protocol.	Results from the study demonstrate the potential role for enhanced passive surveillance (EPS) to improve African Swine Fever detection in the United States.	[16]

				Forest and Boruta Predictive Big Data Analysis Using Neural Network and K- Nearest Neighbor		then processed, data captured from processed images are analysed which results in the opportunity of decision making.	estimation, captured from images, quicker.	statistical results.	weight and growth.	
10	Alessia Dianaa, Lenn Carpentierc, Deborah Piettec, Laura Ann Boylea, Daniel Berckmansc, Tomas Nortonc	2019	Ireland, Belgium	An ethogram of biter and bitten pigs during an ear biting event: first step in the development of a Precision Livestock Farming tool	2 Panasonic camera's	The study developed an ethogram of ear biting behaviour. Through observing the developed ethogram, researchers sought for behavioural features for the development of an algorithm to monitor ear biting behaviour continuously.	The technology shows the potential development of an intervention strategy that monitors ear biting behaviour and escalation prevention.	A third of ear biting instances were incompletely identified by an ethologist because the bitten pig did not react, or the action of ear-to-mouth did not occur. This suggests that future technologies may encounter similar problems.	A combination of biter behaviours and bitten pig responses can be used as variables in an algorithm. Furthermore, the duration of non-vocal behaviour is explored to automatically extract mentioned variables from video recordings.	[20]
11	Nicholas J. Black, Luis E. Moraes, Andreia G. Arruda	2021	United States of America	Association between different types of within-farm worker movements and number of pigs weaned per sow in U.S. Swine farms	Pig Champ Pro Europa, STATA 15	The study utilized an internal movement monitoring system beacon sensor technology to describe farm-worker movements. From the data captured, the study investigated the association of farm-worker movements and	The monitoring technologies have shown the impact of internal biosecurity on farm-worker movements which may affect measures of productivity.	Sensor inoperability may have caused bias in the study. Moreover, the lack of direct oversight of compliance to the internal movement monitoring system may have	Internal movement monitoring technologies can be successfully applied in the field.	[21]

						number of pigs weaned per sow.		introduced misclassification bias.		
12	Ali Alameer, Stephanie Buijs, Niamh O'Connell, Luke Dalton, Mona Larsen, Lene Pedersen, Ilias Kyriazakis	2022	United Kingdom, Ireland, Denmark, Belgium	Automated detection and quantification of contact behaviour in pigs using deep learning	GoPro cameras, Adobe Premier Pro., Monacar infrared surveillance cameras, Microsoft video codec, YOLO detector, Matlab R2021a, Ubuntu 20.04.2 LTS	The study developed an automated system that quantifies frequency of pig head-to-rear contacts. Furthermore, it proposes a system that identifies complex body parts.	The method provides a means for timely intervention of behavioural changes that occur due to health and welfare compromises.	The method shows a higher rate of incorrect classification for pens with higher pig interaction rates which is due to pig-to-pig occlusions.	The study's method enables quantifying interactions between group housed pigs by using machine learning, image processing, deep learning, and video surveillance.	[22]
13	AliAlameer, Ilias Kyriazakis & Jaume Bacardit	2020	United Kingdom	Automated recognition of postures and drinking behaviour for the detection of compromised health in pigs	RBG cameras, YOLO, Faster R-CNN, MatlabR2019b, ResNet-50	A whole encompassing system was developed to detect postures. From this system Pig behaviours were obtained from images. Individual pig profiles were generated from obtained pig behaviours.	Subtle changes are identified by the method used which a person observing from pen side will not be able to detect.	The proposed system does not account for the pig's head, but instead the structural features of the pig. Detection is limited to the camera field view.	Methods presented in the study automatically detect change in posture and drinking behaviours.	[23]
14	Kuan-Ying Ho, Yu-Jung Tsai, Yan-Fu Kuo	2021	Taiwan	Automatic monitoring of lactation frequency of sows and movement quantification of new-born piglets in farrowing	EfficientNet, LSTM, RetinaNet, SORT, wide-angle USB camera, Pytorch toolbox, ResNet101	The study built embedded systems to acquire the videos. These videos were then transmitted to a cloud server. Videos on the server were converted to images. Software was trained to recognize the	The proposed method is objective and automatic making observation quicker and less labour-intensive.	Some Piglets were partially occluded by metal railing or heat lamps.	The proposed automated method recognizes the lactation behaviour of sows. Moreover, it tracks and quantifies the movements of	[24]

				houses using convolutional neural networks		behaviour of lactation sows and localize piglets. Once, training was complete, piglets were then tracked.			individual piglets in complex videos.	
15	Hengyi Ji, Jionghua Yu, Fengdan Lao, Yanrong Zhuang, Yanbin Wen and Guanghui Teng	2022	China	Automatic Position Detection and Posture Recognition of Grouped Pigs Based on Deep Learning	YOLOX, YOLOv5, Hikvision 2D camera, LabelImg, SimOTA,	The study established a human annotated dataset captured by a 2D camera. Data captured was processed to mitigate the problem of class imbalance. Processed data was used to create an automatic recognition algorithm for pig posture and behaviour.	The lack of a class in a dataset was improved resulting in better recognition of pig sitting postures therefore improving data quality.	The learning ability of technology used may be insufficient if more pigs than accounted for in the study are in camera view.	The proposed method meets the needs of pig position detection and posture recognition in pig production farms. Moreover, it addresses the challenge of automatic recognition of sitting postures among grouped pigs.	[25]
16	Santosh Pandey, Upender Kalwa , Taejoon Kong , Baoqing Guo , Phillip C. Gauger, David J. Peters and Kyoung-Jin Yoon	2021	United States of America, Korea	Behavioral Monitoring Tool for Pig Farmers: Ear Tag Sensors, Machine Intelligence, and Technology Adoption Roadmap	Infrared temperature sensor, 3-axis accelerometer, gyroscope, sound sensor, Bluetooth low energy module	The study built an electronic sensor board. Tests were conducted on the built sensor boards both in the laboratory and on farm. Lastly, an investigation in possible machine learning methodologies were conducted to identify attributes of normal versus abnormal pig behaviour and behavioural pigs' well-being indicators.	Automation and integration of various swine activities in swine production.	The collection and analysis of massive qualities of field data with cross validation by farm animal caretakers is a challenge. There is also a risk of damage to the sensory board. Lastly, winning the trust of users is a highlighted challenge for technology adoption.	A electronic sensor board concept that attaches to the ear tags of individual pigs was developed to record pig activities.	[26]

#	Author(s)	Year	Country	Title	Technologies	Strategies/tools/techniques/methods/concepts	Enablers (success)	Barriers (failure)	Core finding	ref
17	Maciej Oczak, Florian Bayer, Sebastian Vetter, Kristina Maschat, Johannes Baumgartner	2021	Austria	Comparison of the automated monitoring of the sow activity in farrowing pens using video and accelerometer data	IP camera, infrared spotlights, Multicam Surveillance system, SMARTBOW system, Interact and Boris labelling software, RetinaNet, Computer Vision Annotation Tool, PyTorch, ResNet-152	The study applied a state-of-the art object detection algorithm of sow activity. Accumulated data were stored in a dataset which involved data processing and data labelling. Evaluation of data was then conducted to compare measurements of sow activity between ear tag, tri-axial accelerometer, gold standard based on human observation, and automated camera-based method.	The object detection technology allows to directly measure the movement of different body parts where an accelerometer is limited to the movement of an ear.	Part of the sow's body are occluded because of the farrowing pen structure. Lighting and the position of camera's determine image quality.	Ear tag accelerometer and object detection of body and head of sows provide similar information on activity levels of animals.	[27]
18	Miguel Garrido-Izard, Eva-Cristina Correa, José-María Requejo and Belén Diezma	2019	Spain, The Netherlands	Continuous Monitoring of Pigs in Fattening Using a Multi-Sensor System: Behavior Patterns	iButton DS1922E loggers, OneWireViewer, Matlab R2018b, Compident MLB	The study distributed pigs accordingly in pens. Temperature measurements and electronic feeding stations were implemented. Captured data was then analysed	The study shows the possibility of establishing a connection between thermal parameters and intake parameters which may be useful for precision phenotyping and animal management	Results show that the rate of pig feed intake is not consistent requiring further data processing to make meaningful visualizations.	The study found that registering the high frequency of animal temperatures in a complete fattening period makes it possibles to identify individuals with different thermal patterns.	[28]
19	Kaidong Lei, Chao Zong, Ting Yang, Shanshan Peng, Pengfei Zhu,	2022	China	Detection and Analysis of Sow Targets Based on Image Vision	Azure Kinect DK, Pytorch, Ubuntu16.04,	The study first developed a sow target detection method that is based on deep learning algorithms. An assessment of two	The use of the study's method enables users to efficiently and accurately identify	Markings on the pig, the pen railing, and the drinking trough affect image segmentation	Sows in a pen can be detected through image segmentation. Moreover, identification of	[29]

	Hao Wang Guanghui Teng and Xiaodong Du					algorithms was conducted to evaluate the algorithm segmentation and recognition performances in sow detection. Lastly, from the results of implementation of algorithms, identity and analysis of sows' behaviours, based on segmentation, was conducted.	physiological behaviours of the sow.	performance negatively.	the sow's behaviour of eating, drinking, and lying is possible.	
20	Chen Shi, Jianlong Zhang and Guanghui Teng	2020	China	Division of Pig Growth Stages According to Body Component Variation using Computer Vision	RFID tags, ground scale with pressure sensors, serial port server, binocular stereo vision acquisition system, photoelectric sensors, Embedded Vision System, relay output model, Laboratory Virtual Instrumentation Engineering Workbench Environment.	The study involved the selection and housing of pigs to be experimented on. Weight scales and relevant sensors were used to capture data. Data captured was analysed using several methods.	The system could enable automatic grouping of pigs based on data analysis results. In addition, it is a simple, low manufacturing cost structure which could be combined with precision feeding systems.	Results show that grower stages ended at different kilograms requiring further data processing to better understand the data.	The study introduces a system that monitors and manages individual pigs which collects data accurately.	[30]
21	Wim Gorssen, CarmenWint	2022	Belgium	Estimating genetics of body	DeepLabCut, Python-based Graphical User	The study combined traditional pig weighing with video analysis.	The study expands pig weighing with a	The study found that defining and scoring	Pigs' body dimensions and activity traits	[31]

#	Author(s)	Year	Country	Title	Technologies	Strategies/tools/techniques/methods/concepts	Enablers (success)	Barriers (failure)	Core finding	ref
	ers, Roel Meyermans, Rudi D'Hooge, Steven Janssens & Nadine Buys			dimensions and activity levels in pigs using automated pose estimation, RFID, ground scale platform, camera	Interface, markerless pose estimation Convolutional Neural Network-based technology		computer vision system, which is able to accurately phenotype pigs body dimensions and activity traits.	behavioural read-outs in pigs is challenging to do on a large scale for application in breeding programs.	were estimated using automated pose estimation and recorded videos	
22	Charlotte Gaillard, Nathalie Quiniou, Raphaël Gauthier, Laetitia Cloutier and Jean-Yves Dourmad	2020	France, Canada	Evaluation of a decision support system for precision feeding of gestating sows	Python, automatic feeder	Farmers and Sensors collect data and store it in a database. Captured data is processed and serves as an input for a nutritional model. The outputs of the nutritional model determines the individual pig's daily nutrient requirements. Requirement instructions are communicated to the automatic feeders.	The decision support system has the potential to integrate several real-time data collections by making use of different sensors which are installed on-farm to characterize housing conditions and animal behaviour. This enables better nutrient supply and requirement decision making.	Information availability is dependent on the equipment available on the farm and the type of data collected.	The developed decision support system allows for the adaptation of the quantity and quality of daily ration's given to sows throughout gestation according to a set criterion.	[12]
23	Harry Wooseuk Ryu, Joo Ho Tai	2022	Korea, Canada	Object detection and tracking using a high-performance artificial intelligence-based 3D depth camera:	AI-based 3D depth camera, Direct X, Unity, ZED software development kit	AI-based 3D depth cameras were used to acquire 3D depth data. The captured data is processed and integrated with AI models. Results after integration are then analysed to formulate a conclusion.	AI will enable farms to detect African Swine Flu symptoms as early as possible remotely and automatically.	Object detection is generally incapable of differentiating individual objects of the same classification.	Prepared custom data sets in an appropriate model farm can train AI models for proper 3D detection. This will be critically important in operating object tracking.	[32]

				towards early detection of African swine fever						
24	Christian Taylor, Jonathan Guy, Jaume Bacardit	2022	United Kingdom	Prediction of growth in grower-finisher pigs using recurrent neural networks	Nedap feeding station, environment control system, temperature sensors	Relevant data was captured and processed. Processed data was used to generate a dataset and served as an input for various machine learning models. Results were then analysed to formulate conclusions.	The study shows all developed models were able to predict the length of time it would take for grower pigs to reach the target finished weight.	Presented results in the paper may have limited use in the global pork industry because of the limited data available to researchers. In addition, few commercial farms can facilitate the collection of individualised daily data on pig liveweight and food consumption.	The study found that an ensemble of long short-term memory models proved the best predictor of pig growth as it utilised average daily temperatures and full daily temperature.	[33]
25	Zhixiong Zeng, Fanguo Zeng, Xiaoteng Han, Hamza Elkhouchlaa, Qiaodong Yu and Enli Lü	2021	China	Real-Time Monitoring of Environmental Parameters in a Commercial Gestating Sow House Using a ZigBee-Based Wireless Sensor Network	Sensors, Mobile devices, Wireless Sensor Network, wireless communication technology, Internet of Things, transmitting terminals	Mobile devices, Cloud servers, and transmitting terminals are installed in a gestation sow house. Sensors capture relevant data which is then processed. Processed data is communicated to the transmitting terminals which is then displayed on a web page.	The system practically contributes to monitoring the microclimate from spatial and temporal perspectives. By deploying the system, real-time monitoring and timely intervention could take place	Wired communication technology encounters problems such as difficult wiring, complex maintenance, and high costs. The capturing of data encounters null entries and requires further processing.	The proposed system, applied in a commercial gestating sow confinement building, proves to be helpful with microclimate management accurately and effectively by real-time monitoring of four environmental parameters. ABSTRACT

In today's fast-paced and highly competitive industrial landscape, achieving optimal efficiency is the key to success. This review compares the fundamental facility layout design principles of industrial engineering with those of cattle handling facilities. This comparison is achieved through an integrative literature study on facility layout design principles, consisting of 1) a narrative literature review on industrial engineering principles and 2) a rapid systematic review of cattle handling facility design principles. By examining these principles side by side, we aim to identify the correlations and variations that exist and unearth opportunities for mutual enrichment and interaction between these seemingly disparate fields, to enhance both operational efficiency and improved production. A Venn diagram has been constructed to illustrate the relationship between these principles. This review offers valuable insights for industrial engineers, livestock managers, and researchers seeking innovative approaches to optimise operational performance and improve facility layout designs in diverse industrial and agricultural settings.

Keywords: cattle handling, facility, layout, design, principles, industrial engineering

1 INTRODUCTION

The pursuit of operational excellence and efficiency is a constant challenge. Organisations are continually seeking innovative ways to streamline their operations and enhance productivity [1]. While many factors contribute to overall efficiency, one aspect with significant implications is the facility layout of such organisations. The importance of a well-designed facility layout cannot be overstated as it directly impacts the overall functioning of a physical workspace. This holds true not only in industrial settings but also in the intricate world of agriculture. It goes beyond mere aesthetics and holds the power to reshape workflows, reduce bottlenecks, and maximise resource utilisation [2].

Cattle feedlots are a specialised type of agriculture operation focusing on managing, raising, growing, and fattening cattle until they reach slaughter weight for meat production [3]. The advantage of feedlots is raising a large number of cattle on less land with fewer inputs, which results in maximum production at minimum cost. Feedlots strive for better productivity to drive profitability while ensuring animal welfare. Handling facilities are needed at feedlots to guide cattle in the desired direction for sorting, feeding, and handling. Cattle handling facilities demand a specialised set of design principles focussing on animal behaviour to ensure animal welfare, worker safety, optimised handling processes, and minimised stress on the cattle [4].

The heavier the cattle in weight, the better income they will receive if cattle are sold as beef. Thus, proper design, maintenance, and operation of these facilities can help minimise stress injury and improve the overall productivity and profitability of the livestock producers [5]. Therefore, it becomes imperative for feedlot operators to carefully consider the design and layout of their facilities, taking into consideration the unique needs of the cattle they handle.

Unfortunately, sometimes feedlot facilities fall short of meeting these objectives resulting in an inefficient facility layout that inhibits the flow of cattle. A poor facility layout causes bottlenecks to form in the corrals and cattle chutes leading to unnecessary stress on cattle. Elevated stress levels of cattle lead to increased rates of injury and a reduction in production (growth), leading to economic losses [6]. Furthermore, a poor facility layout will increase labour costs and increase the risk of potential safety hazards to workers [4].

In a similar vein, industrial engineering facility layout principles revolve around strategically organising machinery, workstations, people, and resources to achieve maximum operational efficiency. By applying these principles, industries have successfully improved workflows, reduced operational bottlenecks, and enhanced overall productivity [7].

Both the manufacturing industry and feedlots require proper facility layout to achieve operational excellence. However, there is a significant gap in research regarding the integration of industrial engineering and cattle-handling facility design principles.

By elucidating the parallels, industrial engineers can gain new perspectives on facility layout design by embracing the unique challenges and principles of cattle handling. The specialised considerations in cattle handling can offer novel insights into the design and optimisation of facility layouts in industrial settings. Simultaneously, it can demonstrate how the application of industrial engineering facility layout design principles can enhance cattle handling practices at feedlots.

The aim of this study is to investigate the relationship between industrial engineering facility design principles and cattle handling facility design principles. By comparing these principles, we can uncover the potential synergies, determining how they can mutually reinforce and contribute to one another, in the pursuit of better production and increased profitability.

The next section explains the method that was followed, while section 3 and 4 provide the findings and discussions. The review is concluded in section 5, with future research recommendations stated in section 6.

2 METHOD

An integrative literature review was utilised for this study as it is a method that seeks to summarise and synthesise existing knowledge and theories across literature to provide a comprehensive understanding of a topic [8]. It allows for generating new perspectives on a topic and resolving inconsistencies in literature by combining different literature review studies [9].

This method was followed to establish the possible correlations and variations between cattle handling and industrial engineering facility design principles. The findings of a 1) rapid systematic literature review and 2) a narrative literature review, were integrated to identify relationships concerning the respective principles.

2.1 Integrative literature review

The integrative literature review followed the 5-stage framework by Whittemore and Knafl [8] and is illustrated in Figure 1.

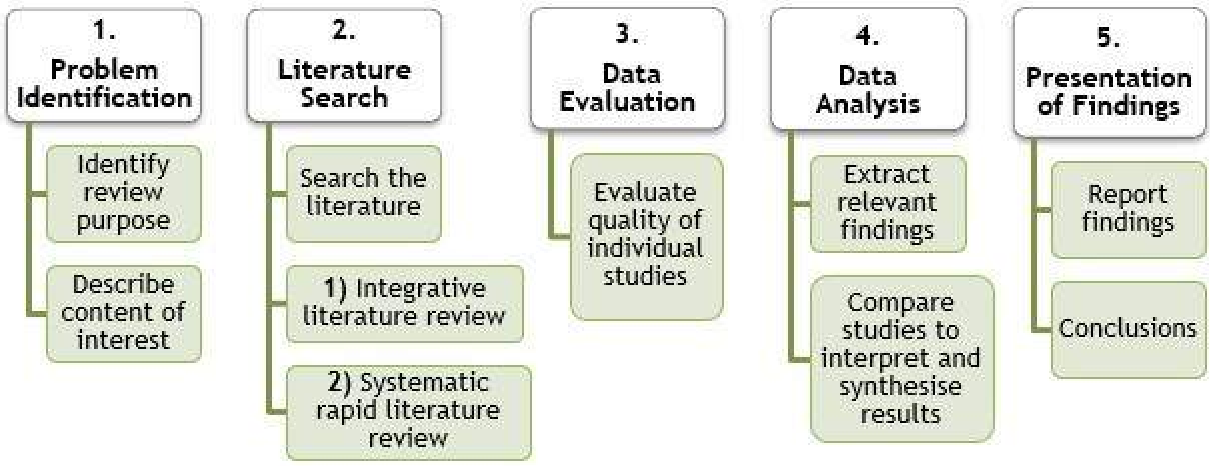

Figure 1:Integrative review methodology framework (Adapted from Whittemore and Knafl [8])

2.1.1 Stage 1: Problem identification

An integrative literature review was done to acquire practical insights into industrial engineering and cattle handling facility design principles. This review aimed to bridge the gap between these facility layout design principles. It has uncovered the correlations, explored the variations, and harnessed the collective wisdom of these domains to pave the way for a more efficient, sustainable, productive, and harmonious future.

2.1.2 Stage 2: Literature search

The literature review consisted of two separate literature reviews the findings of which were compared:

1) Since abundant information is available, a narrative literature review was conducted on Industrial Engineering facility design principles. (Detail of the method followed is discussed in Section 2.2)

2) A more specific systematic rapid literature review on cattle handling facility design principles was conducted. (Details of the method followed are discussed in Section 2.3.)

2.1.3 Stage 3: Data evaluation

Data evaluation entails the evaluation of the literature from each review based on their respective evaluation criteria, which can be found in Section 2.2 and Section 2.3.

2.1.4 Stage 4: Data analysis

Data analysis requires the extraction of key information from each study and comparison of the reviews to synthesise the results [9]. This will allow for the identification of the relationship between both reviews' findings where areas correlate and vary.

2.1.5 Stage 5: Presentation of findings

The key insights derived from the findings are effectively summarised and communicated. A Venn diagram allows for the representation of the research gaps and how the findings complement one another.

2.2 Narrative literature review - Engineering facility design principles

A general narrative literature review was conducted to extract information regarding facility layout design principles within the industrial engineering field. The purpose of this review was to synthesise and analyse a wide range of literature by combining various sources to construct a coherent narrative that highlights the current body of knowledge about industrial engineering facility layout design principles [10]. The following method of Green *et al.* [10] was adapted and followed for the review.

2.2.1 Objective

The industrial engineering facility design principles applicable to various industries were identified and established. The aim was to provide a comprehensive overview of the key principles contributing to efficient facility design and optimisation.

2.2.2 Search Strategy

Various electronic databases and books were searched to explore existing research that provided a comprehensive understanding of the topic [10]. The search terms used to obtain data were "industrial engineering" AND "facility layout design principles".

2.2.3 Inclusion and Exclusion Criteria

Sources were screened based on their relevance to industrial engineering facility design principles. Relevance refers to the degree to which the information provided by the source aligns with the research topic being investigated. Inclusion criteria included sources directly addressing these principles in an industrial engineering context. Sources that did not meet these criteria or were not specific to facility design principles were excluded.

2.2.4 Selection Process

Sources were reviewed to identify relevant studies. The full texts of the selected sources were thoroughly examined to extract pertinent information related to industrial engineering facility design principles.

2.2.5 Data Extraction

Relevant data were extracted from the selected sources. The information was organised in a structured manner to facilitate further analysis.

2.2.6 Synthesis of Findings

Recurring data and key findings were highlighted to provide a comprehensive overview of the principles. The findings are summarised and analysed in section 3.1 to compare them to the findings of the rapid systematic literature review (SLR).

2.2.7 Critical Evaluation

The findings were compared with existing knowledge to ensure a comprehensive and reliable representation of industrial engineering facility design principles.

2.3 Rapid systematic literature review - cattle handling facility design principles

A rapid SLR was conducted to explore cattle handling facility design principles. The review was accomplished by searching a specific database using predetermined keywords.

The reason for the rapid SLR is to extract as much information as was available on cattle handling facility design principles in a timely and comprehensive manner while still adhering to the rigorous methodology of a traditional systematic literature review [11].

Xiao and Watson [12] provide a methodological framework for conducting systematic reviews which is embedded with verification and validation within the steps to ensure rigour throughout the process. This framework was followed for the rapid SLR and is illustrated in Figure 2.

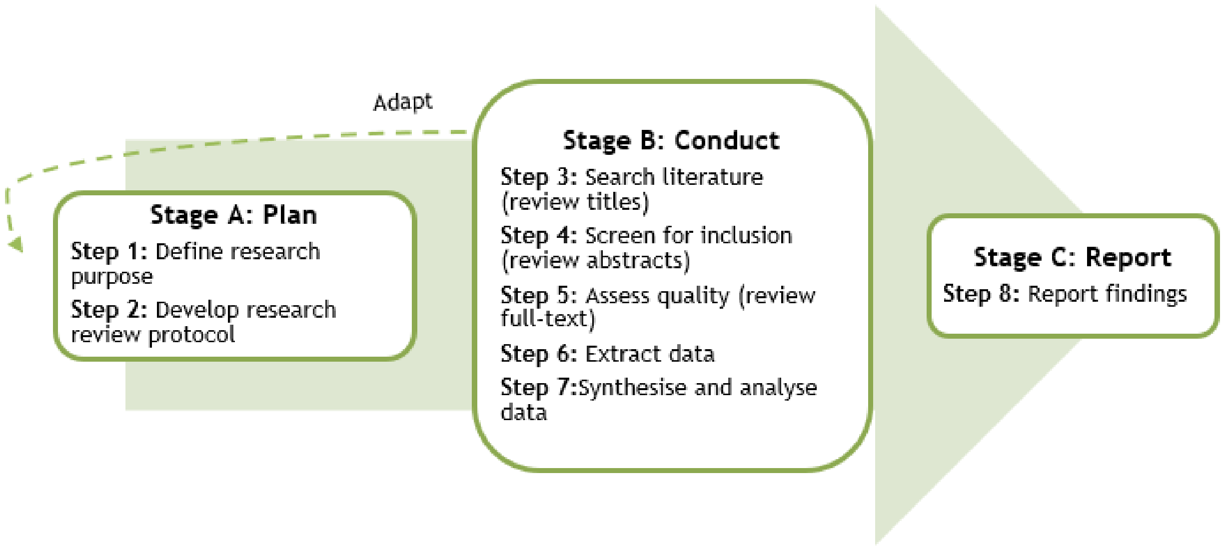

Figure 2: Method of Systematic Literature Review (Adapted from Xiao & Watson [12])

2.3.1 <u>Step 1:</u> Define research purpose

The purpose of the rapid SLR is to investigate the available literature on cattle handling facility layout design principles.

2.3.2 <u>Step 2:</u> Develop research protocol

Table 1 represents the research review protocol followed to guide the search and assess its quality. Following the protocol inclusion and exclusion criteria will remove research bias. For the rapid SLR only one scientific database will be utilised - Scopus.

Table 1: Research review protocol

Purpose of the study	To establish cattle handling facility layout design principles
Keywords	"Cattle handling" AND "facility" OR "layout" AND "design" OR "principles"
Inclusion criteria	• Literature on design principles for cattle handling facilities. • Literature on behaviour principles affecting design principles. • Literature on cattle handling facility layouts.
Exclusion criteria	• Literature that is not in English. • Cattle handling facility design literature about transportation or slaughter/abattoir. • Literature on Edu game. • Literature on dairy cattle handling. • Literature on diseases and reproductive performance. • Literature related to the biology of animals. • Literature on nutrients in animal feed.
Search databases	• Scopus
Quality assessment criteria	• Literature that provides reliable and valid information related to cattle handling principles. • The use of correct scientific methods during the research study.

2.3.3 Steps 3 to 5: Selection process

The search yielded 57 sources using the database and keywords mentioned in the review protocol. The titles of the sources were reviewed, and the inclusion and exclusion protocols were applied.

Thereafter, the abstracts of the sources were screened for inclusion using the criteria stated in the review protocol. It was determined that ten sources met the criteria after the screening of the abstracts. It was assessed based on the sources' correct interpretation of the keywords and checking the sources against the exclusion criteria. The literature that was discarded had no relevance relating to the design of cattle handling facilities. The focus of these studies relates to factors affecting bruises on carcasses, cattle behaviour during transport and slaughter and dairy cattle handling practices.

The full text of the ten sources was reviewed to determine the quality and reliability of the literature. Finally, seven sources were deemed eligible for use after quality assessment. The excluded literature was invalid and not related to cattle handling facility design principles. The literature was on an experiment conducted on designing and assessing animal welfare rather than focussing on facility layout design principles. Moreover, the literature was about the effect of stockperson handling on cattle behaviour. The process for selecting relevant sources on cattle handling facility design principles is depicted in Figure 3. It displays the different processes of the search, the number of sources found, and how this number decreased through the different selection processes.

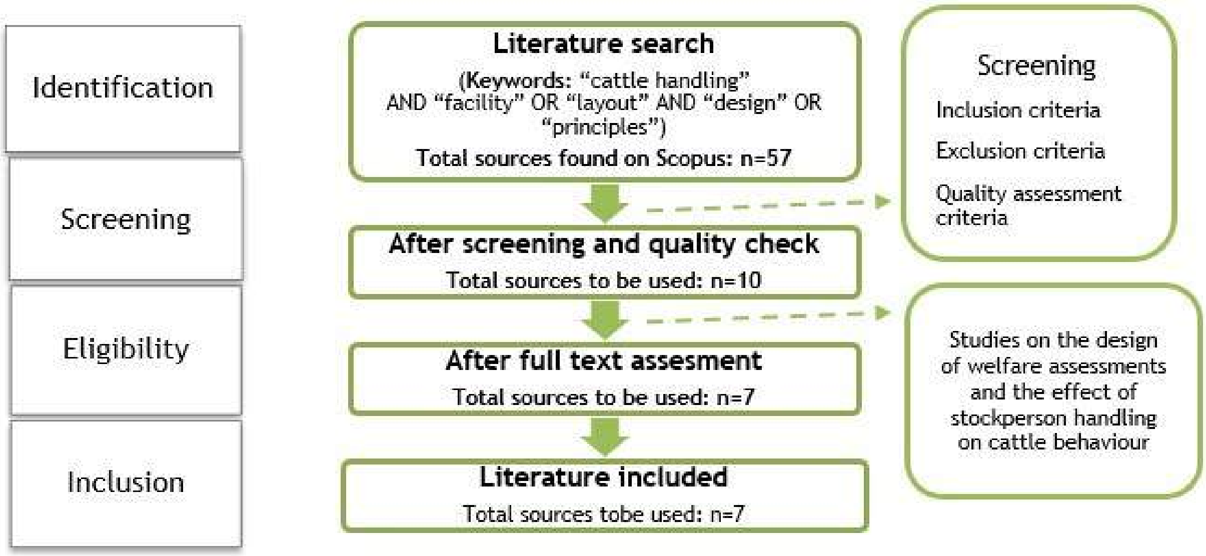

Figure 3: Selection process chart

2.3.4 *<u>Step 6:</u> Data extraction*

After the selection process, seven sources met the criteria and were eligible to be included in the study. The applicable literature on cattle handling facility design principles is presented in Table 2.

Table 2: Data extracted from applicable literature

2.3.5 *<u>Steps 7 to 8:</u> Data analysis and report findings*

The findings of the sources listed in Table 2 are analysed and summarised in section 3.2 so that they can be compared to the findings of the narrative literature review.

3 FINDINGS

The findings from each literature review are represented in separate tables to provide a summary and overview of the literature extracted from 1) the narrative literature review on industrial engineering facility design principles and 2) the rapid systematic literature review on cattle handling facility design principles.

3.1 Narrative literature review

Table 3 presents the findings of the narrative literature review conducted on industrial engineering facility design principles. It provides a summary of each principle, highlighting the core focus and objectives within the context of facility design.

Table 3: Industrial engineering facility design principles

Design Principles	Summary
Workflow optimisation	Optimising the flow of materials, information, and people within the facility. Designed to avoid bottlenecks and interruptions. Emphasises minimising waste and maximising productivity [20].
Operation efficiency	Related processes, inventory and equipment should be located near each other to minimise movement but also to facilitate material handling and process efficiency [20].
Lean manufacturing	Incorporate lean manufacturing principles. Focus on minimising inventory storage, creating clear visual cues, and facilitating smooth material flow [21].
Ergonomics	Considers the design of workstations and equipment to ensure optimal human performance and safety. Emphasises ergonomic principles to reduce strain and enhance worker comfort [22].
Space utilisation	Maximises the efficient utilisation of available space within the facility, ensuring optimal placement of equipment and resources. Aims to minimise empty or unused spaces and maximise storage capacity [20].
Safety	Incorporates safety measures to create a secure working environment, preventing accidents and promoting employee well-being [22].
Management	Apply supply chain principles to optimise the flow of materials, information, and resources across the facility and its external partners [21].
Flexibility	Enables easy modifications. Changes should be made with minimal interruption to production. Allows for future expansion or reconfiguration to accommodate evolving needs [20].
Accessibility	Considers the ease of movement and accessibility for personnel, equipment, and materials. Ensures efficient flow and reduces travel distances within the facility [22].

Design Principles	Summary
Visibility	Focuses on adequate ability for supervision with clear lines of sight, foot access and visibility across the facility to enhance monitoring and control [22].
Sustainability	Consider energy-efficient design principles to minimise environmental impact and reduce operating costs [22].
Economic feasibility	Finding the right balance between cost and efficiency that will contribute to overall profitability and long-term sustainability [22].
Technology utilisation	Incorporates advanced technologies, automation, and digital systems to enhance operational efficiency and streamline processes [20].
Regulatory Compliance	Adhere to industry regulations, safety standards, and building codes [22].

3.2 Rapid systematic literature review

Table 4 presents the findings of the rapid systematic review on cattle handling facility layout design principles. It summarises each principle, outlining its focus and objectives within the context of cattle handling.

Table 4: Facility design principles for cattle handling

Principles	Summary
Reduce distractions	Design facility with solid walls and floors, avoiding bright lights and shadows, helps maintain their focus and reduces anxiety during handling [13].
Reduce obstructions	Ensuring that the facility design does not include sharp edges, protrusions, or objects that could potentially harm cattle. Clear path with minimal obstructions ensures the safety of cattle [13].
Cattle flow	Visual barriers, non-slip flooring, and gradual slopes to facilitate smooth and efficient movement of cattle for handling operations. Minimises congestion, reduces handling time, and optimises the overall workflow [18].
Prioritise animal welfare	Gentle handling to reduce stress and improve the overall well-being, safety, and comfort of the cattle. It includes investing in the necessary infrastructure and resources. Providing shaded areas, proper ventilation, and non-slip flooring can further enhance animal welfare [17].
Sufficient Space	Providing enough space for cattle to move freely to allow cattle to move comfortably and avoid overcrowding, which can lead to stress and injury [14].
Adequate infrastructure	Ensure a robust and durable system capable of efficiently handling a large number of cattle, minimising the risk of breakdowns or frequent

Principles	Summary
	replacements, thereby maximising productivity and reducing long-term maintenance costs [15].
Efficient handling operations	Selection and placement of equipment. Enables efficient and safe handling, sorting, and containment of cattle. Consider resource placement to optimise the flow of handling operations while minimising unnecessary movement and resource wastage [19].
Safety	Use safety measures and protocols to minimise risks and injuries to both cattle and handlers. Ensure secure and controlled handling environments to prevent accidents or escapes [15].
Worker efficiency	Optimise layout to enhance worker efficiency during cattle handling tasks, reduce fatigue, and streamline processes. Consider factors like access to tools and clear communication [19].
Ease of cleaning	Facilitate easy cleaning and maintenance of the facility to maintain hygiene and reduce the risk of diseases. Efficient removal of waste to promote a healthy environment for cattle [14].
Low-Stress Handling Techniques	Implementing low-stress handling methods, adopting modern, humane handling practices such as calm and patient approaches, minimising loud noises, and avoiding abrupt movements helps maintain a relaxed environment for the cattle and encourages cooperative behaviour [19].
Cattle Behaviour	Incorporating an understanding of cattle behaviour into the facility design, considering their natural instincts, social hierarchy, and movement patterns [16].
Flexibility	Design for adaptability to accommodate different sizes and various types of cattle [13].
Accessibility & visibility	Workstations, equipment, and pathways designed to provide clear visibility and easy access for personnel, allowing for efficient monitoring and handling of the cattle [18].
Welfare regulations	Comply with animal welfare regulations and guidelines [16].
Training workers	Train workers to handle livestock, considering cattle flight zones, thereby minimising stress effectively and ensuring the safety of the cattle and maximising operational efficiency [19].

4 DISCUSSION

The exploration of cattle handling and industrial engineering facility design principles reveals an overlap and shared principles between the two domains. A closer examination reveals that both domains recognise the importance of layout optimisation, workflow analysis, and safety considerations.

There are notable similarities between these design principles. However, there are also variations since industrial engineering principles provide a more comprehensive approach to facility design across various industries, while cattle handling principles offer specialised insights specific to the unique challenges and requirements of handling livestock, which may not be fully captured by general industrial engineering design principles.

A visual representation of the correlations and variations amongst the respective principles is depicted in a Venn diagram (Fig 4). The correlations are further discussed in Section 4.1 and the variations in Section 4.2.

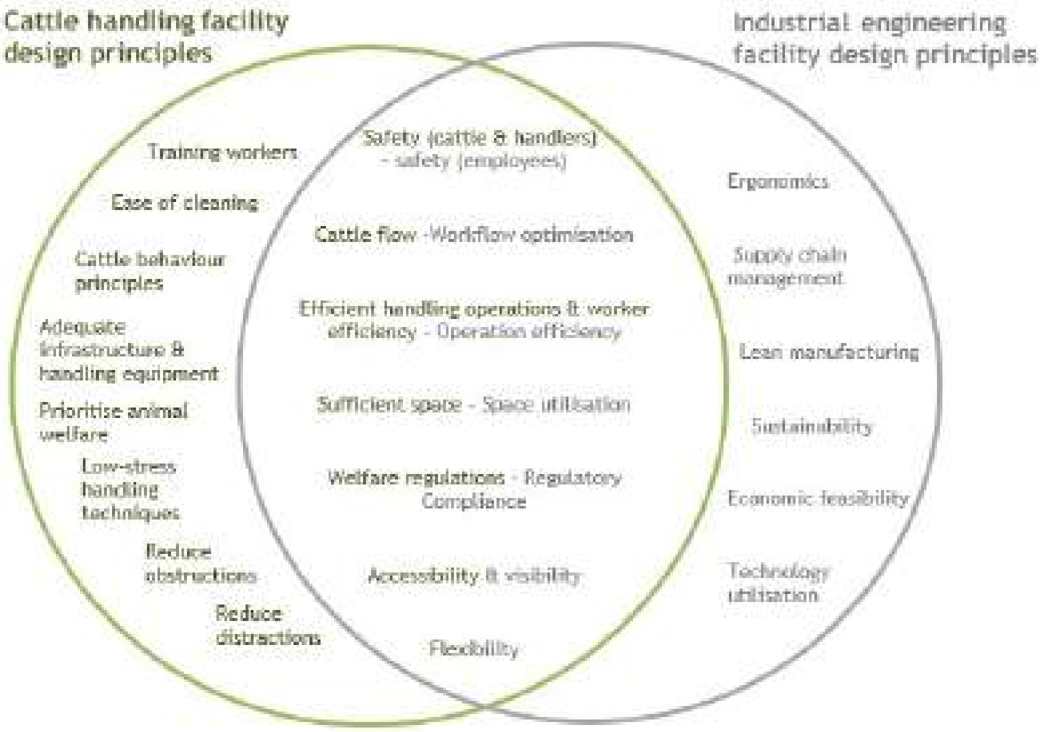

Figure 4: Venn diagram of correlations and variations between industrial engineering- and cattle handling facility design principles

4.1 Correlations

The correlations between cattle handling facility design principles and industrial engineering design principles are captured in a comparison table (Table 5). These correlations highlight the distinct objectives and considerations that shape the design principles in cattle handling facilities and industrial engineering, reflecting the specific needs and challenges of each industry.

Table 5: Correlation between facility layout design principles in Industrial Engineering and Cattle handling

Principle	Cattle handling	Industrial engineering
Safety	Incorporation of safety measures and low-stress animal handling techniques to minimise injury of both cattle and workers. Ensuring a safe working environment.	Implementing ergonomic workstations and safety measures to create a safe and comfortable working environment for employees.
Flow	*Cattle flow* - Attention to animal behaviour, cattle movement and	*Workflow* - Analysing material flow and movement patterns to minimise

Principle	Cattle handling	Industrial engineering
	designing chutes, gates, and alleys to facilitate smooth and controlled movement of livestock. (Minimise stress and congestion).	bottlenecks and streamline workflow. (Optimise process and remove waste).
Efficiency	*Handling and worker operations* - Appropriate equipment and resource placement to optimise the flow of handling operations while minimising unnecessary movement and resource wastage. (Improve livestock handling efficiency)	*Operation efficiency* - Related processes, inventory and equipment should be located near each other to minimise movement but also to facilitate material handling and process efficiency.
Space	Sufficient space - Provide enough space for cattle to move freely and comfortably to avoid overcrowding, which can lead to stress and injury.	Space utilisation - Efficiently utilise space to optimise workflow and productivity.
Regulations	Compliance with animal welfare regulations and guidelines to ensure humane treatment.	Compliance with relevant industry regulations, safety standards, and building codes.
Accessibility & visibility	Proper positioning of the equipment, infrastructure, and pathways to maximise operator visibility and accessibility while minimising distractions for livestock. (Efficient monitoring and handling of the cattle).	Considers the ease of movement and accessibility for personnel, equipment, and materials. Consideration of operator visibility to maximise productivity and minimise errors.
Flexibility	Design facilities that can handle different sizes and types of cattle.	Design for adaptability to accommodate changes in production demands.

4.2 Variations

The variations between cattle handling - and industrial engineering facility layout design principles occur due to the nature of the industries they serve and the specific objectives they aim to achieve. While both share the goal of improving operational efficiency, they differ in their primary focus areas. Cattle handling principles strongly stress the importance of animal welfare, cattle behaviour and the reduction of stress (for the animal) during handling processes. On the other hand, industrial engineering principles prioritise factors such as worker (human) ergonomics, automation and technology integration, and lean manufacturing within industrial settings. These differences stem from the distinct challenges and requirements of each industry, revealing the need for tailored approaches to facility design to meet specific objectives effectively.

4.2.1 Cattle handling principles

The literature reviews showed that cattle handling facilities employ principles in their layout design that are distinct from industrial engineering design principles. However, industries can learn from these principles:

4.2.1.1 Training Workers:

Providing proper training programmes to handlers will ensure that they have the necessary skills and knowledge to handle cattle safely and effectively. The training includes teaching workers proper handling techniques, understanding cattle behaviour, and promoting gentle and humane handling practices.

Implementing training programmes for workers in industrial settings can enhance safety protocols, reduce the risk of accidents or injuries, and improve overall operational efficiency. Well-trained workers are better equipped to handle machinery, follow procedures accurately, and make informed decisions, thereby reducing human error and optimising productivity. Moreover, training programs can foster a culture of continuous improvement, where workers are encouraged to share their knowledge, learn from each other's experiences, and contribute to the overall growth and success of the organisation. Investing in worker training in an industrial setting will enhance employee morale.

4.2.1.2 Ease of Cleaning:

The principle will permit the maintenance of hygiene and prevent disease transmission. The design includes easy access to all areas, including chutes, pens and alleys, to facilitate thorough cleaning and disinfection. Proper drainage systems and smooth surfaces will also aid in efficient cleaning processes.

The principle can be applied to various industries by ensuring hygienic and easily maintainable environments. Industries can improve cleanliness standards and maintain a safe and healthy working environment for employees.

4.2.1.3 Cattle behaviour principles:

Feedlots showcase a diverse range of physical and behavioural variations among cattle, reflecting differences in breeds, growth rates, temperaments and responses to the feedlot environment. Therefore, it is imperative to understand and account for cattle behaviour. The facility layout should align with natural cattle movement patterns to facilitate smooth flow and minimise sudden visual barriers that may cause distress to the animals.

Industries can leverage insights from cattle behaviour principles observed at feedlots to implement efficient processes within their own operations.

4.2.1.4 Adequate Handling Equipment and Infrastructure:

In cattle handling facilities, well-designed chutes, gates, and pens are necessary to facilitate smooth movement and sorting of cattle. Sturdy infrastructure is needed to ensure the safety of both animals and handlers, reducing the risk of accidents or injuries during handling.

Having adequate infrastructure and equipment in an industrial organisation is crucial to ensure the safety of employees by providing them with reliable and well-maintained machinery and facilities. It enables efficient and smooth operations, reducing downtime and maximising productivity.

4.2.1.5 Prioritise Animal Welfare:

Gentle handling is utilised to reduce stress and improve the overall well-being, safety, and comfort of the cattle. Providing shaded areas, proper ventilation and non-slip flooring can further enhance animal welfare.

Industries can learn from the animal handling environment by prioritising human welfare in an organisation. Prioritising the safety and comfort of workers will lead to improved operational efficiency and worker satisfaction.

4.2.1.6 Low-Stress Handling Techniques:

Gentle handling methods will minimise stress in cattle and encourage calm and cooperative behaviour. Minimising loud noises, sudden movements and other potential stressors are also important to keep cattle calm during handling operations.

Cattle handling principles offer unique insights into promoting animal welfare and ensuring safe and stress-free handling procedures. Industries can learn from these techniques and apply them to enhance worker safety and reduce stress in the workplace.

4.2.1.7 Reduce Obstructions:

Clear pathways, well-placed gates, and adequately designed alleys in cattle handling facilities ensure smooth and unobstructed cattle flow and the safety of cattle.

4.2.1.8 Reduce Distractions:

Avoiding visual distractions and reducing noise levels in cattle handling facilities will maintain cattle cooperation and focus during handling. Minimal distractions will result in stress free handling operations.

Creating layouts in the industry that align with natural movement patterns, minimal distractions, and obstructions can lead to improved operational efficiency.

4.2.2 Industrial engineering principles

Industrial engineers utilise principles that are distinct from cattle handling principles when designing facilities. However, these principles could be used to improve cattle handling facilities:

4.2.2.1 Principles of Ergonomics:

Ergonomics refers to designing workstations and equipment layouts that promote worker safety, comfort, and productivity. The principles of ergonomics involve accounting for factors such as proper lighting, ventilation, noise control, and ergonomic design of tools and equipment.

In the feedlot environment, cattle handlers would compromise their own comfort to prioritise the welfare of the cattle. This contrast underscores the intricate balance that must be struck between human comfort and animal welfare within the context of cattle feedlots, to ensure both human and animal needs are met effectively.

Principles of ergonomics can be adapted to design layouts that also prioritise the comfort of workers (not just animals) during handling operations. Applying ergonomic principles to cattle handling systems could reduce fatigue, injury and improve production efficiency.

4.2.2.2 Supply chain management principles:

Supply chain management principles optimise the flow of materials, information, and resources across the facility and its external partners. The principles include inventory management, supplier collaboration, and demand forecasting to enhance overall supply chain efficiency.

These principles can be applied at cattle feedlots by implementing effective inventory management systems, collaborating with suppliers to ensure timely delivery of feed and other resources, and utilising demand forecasting techniques to enhance overall efficiency and minimise disruptions.

4.2.2.3 Principles of lean manufacturing:

Lean manufacturing requires eliminating waste, reducing variability, and streamlining processes. Lean manufacturing involves techniques such as value stream mapping, just-in-time production, and continuous improvement to maximise efficiency.

In the feedlot environment these principles could be utilised to optimise workflow and minimise unnecessary movement of cattle and workers.

4.2.2.4 Sustainability and environmental factors:

Sustainability and environmental factors incorporate energy efficiency and waste reduction measures into facility designs. It involves implementing energy-saving measures, recycling programmes, and sustainable material selection.

These factors can be integrated into the design of feedlot facilities to minimise the environmental impact of livestock operations.

4.2.2.5 Principles of economic feasibility:

Economic feasibility studies focus on balancing cost-effectiveness with operational efficiency by considering factors such as resource utilisation, space optimisation, equipment selection, and labour allocation. The aim is to create facility layouts that minimise unnecessary expenses while maximising productivity and profitability and to create sustainable and financially viable solutions that optimise resource utilisation and contribute to long-term success.

These principles can be applied in the feedlot environment by optimising resource utilisation and minimising unnecessary expenses. Feedlots could invest in durable equipment and infrastructure to reduce maintenance costs and the need for frequent replacements. By making this investment, feedlots could save money in the long run and improve their overall financial stability. An economical and efficient facility layout can contribute to cost savings by optimising labour utilisation and maximising the output per worker.

4.2.2.6 Automation and technology integration:

Integrating automation and technology improves productivity and efficiency and reduces human error. The integration can include the use of robotics, automated material handling systems, and data-driven decision-making tools.

In the feedlot environment, utilising technology and automation will improve productivity. Implementing robotics and automated material handling systems could enhance the speed and precision of cattle movement and sorting. Additionally, technology integration for tracking, identification and data analysis could optimise handling processes.

5 CONCLUSIONS

This review has examined the fundamental design principles of industrial engineering facility layouts and compared them with the design principles applied in cattle handling facilities. The intricate puzzle of merging these distinct fields, emphasises the comforting truth that solutions exist even in complex integrations. This review visually mirrors the convergence through a Venn diagram, elucidating the overlapping puzzle pieces where these principles offer potential mutual enrichment and interaction. Furthermore, to the researcher's knowledge at the time of publication, it is believed that this study is the first comparison concerning these distinct facility design principles.

The overlap between industrial engineering principles and cattle handling principles lies in the shared goals of operation efficiency, productivity and safety. Both fields recognise the importance of eliminating waste, reducing variability and streamlining processes. Integrating best practices from both domains will enhance facility layout designs, improve production, and increase profitability in both industry and agriculture settings.

The similarities between these principles underscore the critical importance of a well-designed facility layout. The shared emphasis on creating efficient and effective facility layouts highlights the universal need for thoughtful design considerations and their influence on overall operational success.

The divide between industrial engineering facility design principles and cattle handling facility design principles is rooted in the distinct nature of these domains. The disparity is particularly evident in the realm of ergonomics, where a notable contradiction arises. Industrial ergonomics is primarily driven by optimising human comfort, while cattle handlers compromise their own comfort to prioritise the well-being of the cattle.

Despite their apparent differences, there exists a connection that remains largely unexplored. The knowledge and insights to be gained from this exploration can lead to transformative advances in operational efficiency and hold value for professionals in both industry and livestock sectors.

6 FUTURE RESEARCH

Future research should explore the potential for further integration between industrial engineering principles and cattle handling principles to continue to explore relationships between these principles, facilitate knowledge exchange, and foster collaboration to unlock new possibilities for operational excellence.

By leveraging these design principles, it will become possible to enhance cattle handling facility layouts through insights and strategies derived from industrial engineering, ultimately leading to improved productivity, safety, and economic feasibility.

Further research should also address the specific challenges faced by different sectors within the livestock industry and explore tailored solutions to optimise operational performance and animal welfare.

Additionally, there is a need to bridge the gap in research between theoretical principles and practical implementation. Future research could conduct field studies to assess the real-world effectiveness of different facility layout designs. By closely examining how these designs function in practical scenarios, researchers can gain valuable insights into their actual performance and identify areas for improvement. Moreover, future research could conduct field studies to evaluate real-world challenges. This would entail observing and analysing the current issues and obstacles encountered at feedlots, enabling researchers to develop more informed and effective solutions that align theory with practical application.

ABSTRACT

Financial institutions are rapidly adopting Agile to speed up the development of products and services. In such a highly regulated industry the adoption of a Software Development Life Cycle (SDLC) is hampered by the organisation's existing structure and culture. This paper investigates how a financial institution's organisational structure and culture influence its SDLC decision-making process to ensure that Agile is accepted by the organisation. A survey of 80 project practitioners in various South African financial institutions and hypothesis testing revealed that the organisational structure factors of management style and work ways and the organisational culture factor of work style have a significant positive influence on SDLC decision-making in a financial institution. The research indicates that the way the organisation approaches decision-making influences the perceived acceptance of agile. Financial institutions are encouraged to regularly review their organisational structure, culture, and decision-making to ensure that it is aligned with their development strategy.

Keywords: Organisational culture, organisational structure, agile, financial institutions, South Africa

1. INTRODUCTION

Financial institutions operate in a very competitive environment to produce innovative products and services for their customers [1]. In South Africa, financial institutions are known for being very innovative and providing solutions that cater to their customers' needs. South African banks are ranked amongst the top 15 banks on the African continent with Standard Bank, First National Bank (FNB), Amalgamated Bank of South Africa (Absa), and Nedbank holding the Top 4 positions [2]. The solutions financial institutions develop are dependent on information technology (IT) infrastructure and require a software development approach. The rapid evolution of technology is forcing the financial industry to embrace digitisation, which requires this industry to align its business with information technology (IT). Various competitive factors have created a strategic need for financial institutions to be more agile, so that they can respond quickly and adapt faster while delivering greater value and keeping their existing market share [1]. This is the reason why most financial institutions are transitioning from a traditional waterfall methodology to an agile methodology as their preferred Software Development Life Cycle (SDLC). An SDLC is the framework that is used to plan, manage, and control the process of developing an information system (Bassil, 2012). There are seven different SDLC methodologies namely agile, lean, waterfall, iterative, spiral and dev-ops. This paper investigates how an organisation goes about adopting a new SDLC methodology such as agile based on its existing organisational culture and structure.

Agile methodology is based on the agile manifesto, which is a set of guiding principles of practice. The agile manifesto promotes values of collaboration over contract negotiations, adapting to change over following a specific plan, having a working solution over comprehensive documentation, and finally, human interactions over tools and processes [3]. These values speak to an organisation's culture and structure.

Many studies have investigated agile and agile adoption in organisations [4]. However there has been a much more limited focus on agile studies in financial institutions [5]. Financial institutions differ from the software development industry, where agile is very prevalent. Financial institutions are more traditional and have a lot more regulations, policies, and procedures that they need to comply with. This highly regulated environment provides a level of complexity when implementing an agile methodology. Failing to adhere to these regulations can result in (a) the institutions being fined; (b) reputational damage, and the most serious consequence which is (c) having their financial license revoked. It is due to operating in such a highly regulated environment that financial institutions seemingly have stringent and bureaucratic decision-making processes and have taken a conservative approach to adopting agile [6]. It is therefore important to investigate the factors/dimensions that are unique to the financial industry that determine the successful adoption of agile.

It has been shown that an agile methodology provides a workable solution much faster than when a traditional methodology is used, although organisations often struggle to adapt to agile [7]. Past research shows that software development process changes trigger complex organisational changes and that these changes cannot be accomplished by merely replacing current tools and technologies with new ones [8]. When an organisation decides to adopt an agile methodology it should review its entire structure, management practice, and culture.

The aim of this study is to investigate the organisational structure and culture factors that contribute to a financial institution successfully adopting an agile methodology for its projects.

The objective is to identify the factors relating to an organisation's structure and culture that contribute to the successful adoption of agile methodology in the financial industry.

Given the objectives, the research questions are:

1. How does the organisational structure in the financial industry play a role in the acceptance of an agile methodology?

2. What organisational culture factors ensure a perfect culture for agile adoption in the financial industry?

2. LITERATURE REVIEW

2.1. Organisational culture

Organisational culture is a shared belief system that infuses an organisation or sub-unit and ultimately influences the actions of people and workgroups [9]. Understanding the culture of an organisation ensures that an organisation and its project office choose a software development method that suits the organisational culture irrespective of software development evolution [10]. The culture of an organisation can be categorised according to various typologies. Burns [11] uses the Hofstede dimension framework to measure the culture in an organisation. Organisational culture studies tend to evaluate individualism vs collectivism; power distance; uncertainty avoidance; and masculinity vs. femininity in the organisation [11]. In contrast, Livari and Huisman [12] use a competing value framework (CVM) to determine the organisational culture based on the organisation's value system. The culture types that be identified based on the CVM framework [12] include:

- The group culture - This culture is concerned with morale and human relations. This type of culture values collaboration and the distribution of decision making.
- The development culture – Describes a culture that emphasises growth and the willingness to adapt. This type of culture values communication that is horizontal, and informal coordination.
- The rational culture – This culture focuses on efficiency, productivity, and the achievement of goals. The culture prefers centralised decision making with formal control systems.
- The hierarchical culture - This culture is concerned with control, stability, and efficiency by following formal rules and regulations.

Each culture type mentioned above has its drawbacks which highlights the inherent dilemmas an organisation might have. An organisation may consist of more than one type of culture based on the size and structure of the organisation.

Although organisational culture may be interpreted in various ways, previous studies emphasize that organisational culture influences the adoption of a software development methodology [13], [14].

Moreover, organisational culture or the organisational climate has a significant impact on the work style exhibited by individuals in an organisation [15]. Work style is defined as the appropriate skills and abilities that an individual possesses to be able to do their job [15]. The literature states that work style, management style, communication, and knowledge sharing processes are all important cultural factors that influence the implementation of agile in an organisation [9].

By knowing which factors are indicative of the organisational culture and therefore determine the different culture types, the study aims to establish the organisational culture factors that can influence the acceptance of an agile methodology.

2.2. Agile culture

Agile is defined as "a network of teams within a people-centred culture that operates in rapid learning and fast decision cycles which are enabled by technology, and that is guided by a powerful common purpose to co-create value for all stakeholders" [14]. To determine the quality of agile, one needs to understand agile development from a human and cultural perspective [13]. By knowing the type of culture inherent in an organisation one can gain insight into how that organisation will embrace an agile culture which is part and parcel of adopting an agile methodology. An agile culture encompasses factors that influence the decision-making process in an organisation. Depending on how decision-making power is distributed in the organisation, the organisation and its management can either empower their employees to be self-sufficient and creative or the employees can be disempowered which results in them doing just the bare minimum of what is required. The latter will limit the benefits of adopting an agile methodology in an organisation.

An agile culture changes the way employees coordinate, communicate, and collaborate [16]. Furthermore, there should be alignment between product and project decision making and the organisation's business strategy to ensure the success of the agile strategy in the organisation [16]. An agile culture requires a shared decision-making model to empower the team to not be confined to a specialised role. This implies that decision-making power should not only be vested in the project managers and management of the organisation but also in the team [16]. Moreover, the involvement of team members in the decision-making process may even change based on the phase of the development cycle the team finds itself in. An example of this is that when the team is collaborating, the decision making process should include the input of various stakeholders even though they may have different goals and backgrounds [16].

2.3. Organisational Structure

Organisational structure is defined "as the formal system of task and reporting relationships that controls, coordinates, and motivates employees so that they cooperate to achieve an organisation's goal" [Ajagbe (2017) in 17]. The structure of the organisation determines how tasks are executed which in turn has implications for the performance of that organisation.

Karpik [14] describes the functional structure as a "hierarchical structure where each department consist of employees who report to the functional manager and where the functional manager reports to the head of department who oversees the overall performance of the department" [14].

One of the oldest organisational structures is the hierarchical structure also commonly known as the traditional organisational structure. Burns [18] describes the hierarchical structure as a structure where decision making power is centralised towards the top of the organisation and cascades down. This provides managers with the confidence that they have the authority to manage their units [18]. Funminiyi [19] found that the decision-making process in a hierarchical structure may have a negative impact on the organisation if management is ineffective in motivating employees and providing them with training [19].

A second type of organisational structure is the matrix structure where the organisation is more project-oriented and where teamwork between departments is required. The matrix structure tends to be flexible, but it requires interactions and communication amongst the employees. The level of authority in the matrix structure may not be equally shared between the functional and project managers as it depends on the balance of power in the organisation [14]. One of the organisational benefits of the matrix structure is motivated employees. Motivated employees perform at a high level as they have some sense of autonomy and don't always need to wait for top management to make decisions. The mindset of people working in the matrix structure tends to be more strategic and receptive to new ideas [20].

The third organisational structure is called the flat structure. This type of structure is the opposite of the hierarchical structure in that it typically has few to no management levels [21]. The organisation of the flat structure can be based on projects, production, geography, or division. Funminiyi [19] suggests that the flat structure allows employees to be more creative which increases their productivity as they are more satisfied with their work [19].This is because decision making power is distributed to the employees and everyone is seen as equals.

Based on the literature above how managers manage and direct their employees and how these employees respond to their manager's direction is an important factor that determines the organisation's structure. Olmedo-Cifuentes and Martínez-León [22] named this factor management style. They further suggest that management style can assist in the organisation's brand identity. Management style is described as the manner in which managers of an organisation control and manage their employees [22]. The management style of an organisation also influences how the employees respond to the method of management which then determines employees' work ways.

The literature review indicates that an institution's organisational culture and structure may influence its SDLC decision-making and adoption process with reference to the adoption of agile. However, few studies have investigated these factors in the financial institution context, this is the gap we hope to address with this study.

3. CONCEPTUAL MODEL

The conceptual model shown in Figure 1 below is derived from Chan and Thong's [23] framework for studying agile adoption by reviewing various factors in an organisation that contribute to knowledge management outcomes which will in turn ensure that an agile methodology is successful in an organisation. The conceptual model indicates the organisational structure and culture factors that will be covered in this study. This study will be make use of the organisational culture types identified by Iivari and Huisman [12] namely group culture, developmental culture, hierarchical culture, and rational culture. By identifying the existing culture type(s) in a financial institution one can determine if that culture supports an agile culture which the institution requires to be able to successfully adopt agile.

To identify the organisational structure of a financial institution we will be using the structures identified by Funminiyi, Taylor and Karpik [14], [19], [21] namely the functional, hierarchical, flat and matrix structure.

3.1. Organisational structure factors

The organisational structure factors (See Figure 1) refer to how the organisation is structured in terms of the level and type of hierarchy and the decision-making authority. The management style is indicative of the style of the management that is followed. The style will either be one of mentor and leader where the employees are provided with autonomy and support, or the style can be authoritative and dictating. The work ways factor refers to how the employees perform their duties in relation to management giving them more accountability and responsibility to make decisions and carry out work. These factors have been derived from the literature and are based on studies that determine how the structure of an organisation impacts how decisions are made in an organisation [14], [19], [21].

3.2. Organisational culture factors

Organisation culture factors (see Figure 1) refer to the employees' behaviour in the organisation. These factors provide insight on how the employees perform their duties and to what extent they are involved in decision making in the organisation. Work style refers to the extent to which the organisation encourages teamwork and collaboration from their employees. How the organisation reacts to uncertainty and the distribution of power (power distance) provides more insight on the flexibility of the organisation.

3.3. Agile culture factors
